

## Properties of Logarithms

- The properties of **logarithms** follow directly from the properties of exponents. Keep in mind that “a log is an exponent.”
- REMEMBER:** A log is an exponent!
- A log written without a "b" value is the **common log**.

$$y = \log x$$

In a common log, the "b" value is understood to be 10. In other words,  $y = \log x$  is equivalent to the statement  $10^y = x$ .

<p><b>The log of a product</b></p> $\log_b (xy) = \log_b x + \log_b y$ <p style="text-align: center;"><i>sum of two logs</i></p>	<p>When dealing with a product of exponents of the same base, you add the exponents.</p> <p>When dealing with the log of a product, you add the logs.</p>
<p><b>The log of a quotient</b></p> $\log_b \left(\frac{x}{y}\right) = \log_b x - \log_b y$ <p style="text-align: center;"><i>difference of two logs</i></p>	<p>When you have a quotient of bases raised to different exponents, you subtract the exponents.</p> <p>When you have the log of a quotient, you subtract the logs.</p>
<p><b>The log of a power</b></p> $\log_b (x^y) = y \log_b x$	<p>When you raise a number with an exponent to another power, you multiply the exponents.</p> <p>When taking the log of a number raised to another power, you multiply that number by the log.</p>
$\log_b b = 1 \quad b^1 = b$	<p>Here is another useful property of logs.</p> <p><b>REMEMBER:</b> <math>\log_b b = x</math> means <math>b^x = b</math>. The only exponent that produces its base is 1. So, the <math>\log b</math> that produces <math>b</math> has to be 1.</p>
