

Description:

Prompts for input if omitted. It is entirely possible this will be a very obvious answer. This includes detailed settings that were applied with a precedence of 1 and higher. It won't allow me to delete the keys. You can remove anything sensitive. Technically, there's nothing wrong with this but it is considered bad practice and makes troubleshooting difficult.

Windows 7 gpresult scope computer access denied - Hi Sorry for the delay, a few unexpected issues came up. However it will show the updated setting in gpedit not that it makes a difference at that point if it can't apply.

In other words, it shows you what Group Policy Objects have been applied and their settings. This is typically one of the first tools I go to when troubleshooting Group Policy from a client once basic connectivity has been confirmed. The tool itself is very simple to use and I will run through some common examples below. It will also display summary data, such as last time group policy was applied, which Domain Controller it was applied from, the site, security groups and if the slow link threshold has been activated. If you want to see both user and computer settings, elevate the command prompt by either tapping the winkey+cmd then ctrl+shift+enter or right click on the command prompt and select run as administrator. To work around this, specify the standard user that you are troubleshooting. This view is particularly nice as you can show all and use ctrl+f to find a particular policy or setting. Click on advanced and review the permissions against the object. In this case you can see that the Seven computer object has been denied Apply Group Policy resulting in the Filtering: Denied Security message. If deny read has been granted every permission will have a red cross next to it.
