Researched in collaboration with the Universities of Pretoria & North West (Potch Campus)

To whom it may concern

SupaZorb South Africa are International specialists in Water purification, Water and soil rehabilitation, Water pollution prevention and Water distribution networks.

SupaZorb received a request from Mr. J. Sadler to test the Sydney 905 filters 0.1 Mic and 0.01 Mic.

Specific micro-organisms were chosen from (Bacteria, Fungus, Yeast and Algae) to measure the efficiency of microbiological removal from pressurised water. (Municipal water pressure).

The results were conclusive at a range of different pressures as successful.

It would be difficult to estimate the duration of sufficiency of this filter as all drinking water (above ground and underground) in Southern Africa is considered polluted with sewer and grave leachate. What is also amazing of this filter, is that once it is saturated with contaminants, the water flow will stop until the filter is backwashed. The cleaning of this filter is a simple reverse flow/backwash of the water and the filter can be re-used.
