

Hot Summer Ahead, Time To Check Your Charge Air Cooler For Leaks

Truck charge air coolers (CACs) can experience several problems during the summer due to high ambient temperatures and increased thermal loads. Common issues:

- High temperatures accelerate the wear and degradation of seals and gaskets, leading to leaks and reduced efficiency.
- Repeated heating and cooling cycles cause the material to fatigue from continual expansion and contraction, leading to cracks and tube-to-header joint leaks. A leaking CAC results in increased fuel consumption and reduced engine power.
- Summer conditions lead to increased accumulation of dirt, bugs, and other debris on the CAC, reducing its efficiency.
- High temperatures and humidity can accelerate corrosion, especially in areas where salt or other corrosive substances are present. This can compromise the structural integrity of the CAC.

To keep your truck on the road and to maintain optimum fuel economy it is essential to keep the CAC and radiator clean and well-maintained. Regularly check the CAC for leaks, blockages, and damage.

Discover what a leaking charge air cooler could be costing you by visiting our "Leaking Charge Air Cooler Fuel Cost Calculator".
