

Garage Door Insulation Kit – How to Measure – Instructions

We cut all the insulation panels to size, the length, width and thickness. Essentially, you would measure the garage door sections to have the panels slotted in behind the flanges of the garage door. Please see the below simple steps to measure each section. Please ensure you measure each section as all might not be the same size.

For the length of the panels, from the inside of the flanges, you measure directly from left to right.

For the width, you would measure from up inside the top lip of each section to the top of the bottom lip. (Not to the inside of the bottom lip – as it would be impossible for the panels to slot in the cavity). As for the thickness, you would measure the depth of the slot in which the panels would be slotted into. We would recommend adding 1mm onto the thickness to allow it to be snug/firm in place when installed (This is only optional). If/When the thickness, length or width of the panel is slightly more and is not slotting in easily – sandpaper can be used to sand back a couple of millimetres to suit.

You can order your garage door insulation kit here (double or single):
