Disclaimer:

Supplement recommendations are based on the Organic Acid test results. The prescribing health practitioner must take into consideration the age, weight, sex, and pregnancy or lactation state. In addition, consider clinical state, medication regime, associated drug-nutrient depletion and allergies. The doses listed above are considered optimal, based on lab results and do not apply to specific disease conditions where doses may need to be altered. The vitamins, minerals or amino acids listed are elemental quantities. Use clinical discretion when choosing the right salt with the guidance of your compounding health professional. For example, Magnesium may be prescribed as a glycinate for its calming effect or threonate may be used for a Magnesium that crosses the blood-brain-barrier.

Laboratory Comments

Organic acids provide functional markers for the metabolic effects of micronutrient adequacy, toxic exposure, neuroendocrine activity, intestinal bacterial and fungal overgrowth. Organic acid testing indicates the need for nutrients, diet modification, detoxification, antioxidant protection or further testing.

In a healthy state, organic acids are excreted in the urine at low concentrations. Low range results may be associated with hypometabolic compensatory states. Compensatory responses include hormonal secretions and cytokine responses that can slow or reverse deviations from median or normal physiologic states.

The Krebs cycle is a process of conversion of fats, carbohydrates and protein to mitochondrial energy, ATP.

Metabolic blocks in the Krebs cycle due to insufficient enzymes or cofactors will result in the elevation of organic acids that accumulate and spill into urine.

Carbohydrate Metabolism and Glycolysis

Dietary carbohydrates are broken down into Glucose and other sugars where carbohydrate breakdown products, pyruvate and lactate are formed. Pyruvate enters the Krebs cycle via dehydrogenase enzymes which require vitamin B1 (thiamine), Vit B2 (riboflavin), vitamin B3 (niacin), vitamin B5 (pantothenic acid), and lipoic Acid to function correctly. Review Vitamin B Levels in conjunction with Pyruvate and Lactate levels.

In the absence of these nutrients, lactate builds up leading to lactic acidosis. Elevated pyruvate and lactate can indicate a need for lipoic acid.

Pyruvate

Elevated pyruvate is associated with increased exercise, bacterial, shock, inborn error of metabolism and anaemia.

Consider Vitamin B1 (thiamine), Vitamin B2 (riboflavin), Vitamin B3 (niacin), Vitamin B5 (pantothenic acid), and lipoic Acid.

Methylmalonate (MMA)

Methylmalonyl-Co-A (MMA) is produced from breakdown of isoleucine, Valine, methionine and threonine. MMA is converted into succinic acid via a B12 dependent enzyme Methylmalonyl-Co-A mutase. Elevations in MMA is associated with vitamin B12 deficiency, pernicious anaemia, GI bacterial metabolism, malabsorption or gastroenteritis.

Consider: Vitamin B12.

Bacterial- Dysbiosis

Benzoate and hippurate are metabolically related as substrates and products of the glycine conjugation system. Urinary benzoate and hippurate are functional markers of a common genetic weakness in glycine conjugation.

Benzoate

Benzoate was one of the compounds first found to be elevated in urine from patients with intestinal bacterial overgrowth and a metabolic product of free intestinal phenylalanine. Benzoates are found in jams and foods containing paraben preservatives.

Hippurate

Hippurate is the most abundant marker of dysbiosis because its precursor, benzoate is the principal product of intestinal bacterial metabolism of dietary polyphenols.

Consider a Microbiome assessment to determine microbial overgrowth.

Phenylacetate, Phenylpropionate, p-Hydroxybenzoate, p-Hydroxyphenylacetate

One or more of the phenyl compounds may be elevated due to overgrowth of intestinal bacteria involved in their production from dietary polyphenols or undigested phenylalanine.
