Use of TPM2_SetCommandCodeAuditStatus() to change the list of audited commands is an audited event. If TPM_CC_SetCommandCodeAuditStatus is in *clearList,* the fact that it is in *clearList* is ignored.

NOTE 2 Use of this command to change the audit hash algorithm is not audited and the digest is reset when the command completes. The change in the audit hash algorithm is the evidence that this command was used to change the algorithm.

The commands in *setList* indicate the commands to be added to the list of audited commands and the commands in *clearList* indicate the commands that will no longer be audited. It is not an error if a command in *setList* is already audited or is not implemented. It is not an error if a command in *clearList* is not currently being audited or is not implemented.

If a command code is in both *setList* and *clearList*, then it will not be audited (that is, *setList* shall be processed first).

22 Integrity Collection (PCR)

22.1 Introduction

In TPM 1.2, an Event was hashed using SHA-1 and then the 20-octet digest was extended to a PCR using TPM_Extend(). This specification allows the use of multiple PCR at a given Index, each using a different hash algorithm. Rather than require that the external software generate multiple hashes of the Event with each being extended to a different PCR, the Event data may be sent to the TPM for hashing. This ensures that the resulting digests will properly reflect the algorithms chosen for the PCR even if the calling software is unable to implement the hash algorithm.

NOTE 1 There is continued support for software hashing of events with TPM2_PCR_Extend().

To support recording of an Event that is larger than the TPM input buffer, the caller may use the command sequence described in clause 17.

Change to a PCR requires authorization. The authorization may be with either an authorization value or an authorization policy. The platform-specific specifications determine which PCR may be controlled by policy. All other PCR are controlled by authorization.

If a PCR may be associated with a policy, then the algorithm ID of that policy determines whether the policy is to be applied. If the algorithm ID is not TPM_ALG_NULL, then the policy digest associated with the PCR must match the *policySession→policyDigest* in a policy session. If the algorithm ID is TPM_ALG_NULL, then no policy is present and the authorization requires an EmptyAuth.

If a platform-specific specification indicates that PCR are grouped, then all the PCR in the group use the same authorization policy or authorization value.

pcrUpdateCounter counter will be incremented on the successful completion of any command that modifies (Extends or resets) a PCR unless the platform-specific specification explicitly excludes the PCR from being counted.

NOTE 2 If a command causes PCR in multiple banks to change, the PCR Update Counter must be incremented once for each bank. The commands that extend PCR are: TPM2_PCR_Extend, TPM2_PCR_Event, and TPM2_EventSequenceComplete.

If a command resets PCR in multiple banks, the PCR Update Counter must be incremented only once. The commands that reset PCR are: TPM2_PCR_Reset, and TPM2_Startup.

A platform-specific specification may designate a set of PCR that are under control of the TCB. These PCR may not be modified without the proper authorization. Updates of these PCR shall not cause the PCR Update Counter to increment.

EXAMPLE Updates of the TCB PCR will not cause the PCR update counter to increment because these PCR are changed at the whim of the TCB and may not represent the trust state of the platform.

 Copyright © TCG 2006-2020

22.2 TPM2_PCR_Extend

22.2.1 General Description

This command is used to cause an update to the indicated PCR. The *digests* parameter contains one or more tagged digest values identified by an algorithm ID. For each digest, the PCR associated with *pcrHandle* is Extended into the bank identified by the tag (*hashAlg*).

EXAMPLE A SHA1 digest would be Extended into the SHA1 bank and a SHA256 digest would be Extended into the SHA256 bank.

For each list entry, the TPM will check to see if *pcrNum* is implemented for that algorithm. If so, the TPM shall perform the following operation:

$$PCR.digest_{new}[pcrNum][alg] \coloneqq \mathbf{H}_{alg}(PCR.digest_{old}[pcrNum][alg] \mid\mid data[alg].buffer) \quad (6)$$

where

$\mathbf{H}_{alg}()$	hash function using the hash algorithm associated with the PCR instance
$PCR.digest$	the digest value in a PCR
$pcrNum$	the PCR numeric selector (*pcrHandle*)
alg	the PCR algorithm selector for the digest
$data[alg].buffer$	the bank-specific data to be extended

If no digest value is specified for a bank, then the PCR in that bank is not modified.

NOTE 1 This allows consistent operation of the digests list for all of the Event recording commands.

If a digest is present and the PCR in that bank is not implemented, the digest value is not used.

NOTE 2 If the caller includes digests for algorithms that are not implemented, then the TPM will fail the call because the unmarshalling of *digests* will fail. Each of the entries in the list is a TPMT_HA, which is a hash algorithm followed by a digest. If the algorithm is not implemented, unmarshalling of the *hashAlg* will fail and the TPM will return TPM_RC_HASH.

If the TPM unmarshals the *hashAlg* of a list entry and the unmarshaled value is not a hash algorithm implemented on the TPM, the TPM shall return TPM_RC_HASH.

The *pcrHandle* parameter is allowed to reference TPM_RH_NULL. If so, the input parameters are processed but no action is taken by the TPM. This permits the caller to probe for implemented hash algorithms as an alternative to TPM2_GetCapability.

NOTE 3 This command allows a list of digests so that PCR in all banks may be updated in a single command. While the semantics of this command allow multiple extends to a single PCR bank, this is not the preferred use and the limit on the number of entries in the list make this use somewhat impractical.

22.3 TPM2_PCR_Event

22.3.1 General Description

This command is used to cause an update to the indicated PCR.

The data in *eventData* is hashed using the hash algorithm associated with each bank in which the indicated PCR has been allocated. After the data is hashed, the *digests* list is returned. If the *pcrHandle* references an implemented PCR and not TPM_RH_NULL, the *digests* list is processed as in TPM2_PCR_Extend().

A TPM shall support an *Event.size* of zero through 1,024 inclusive (*Event.size* is an octet count). An *Event.size* of zero indicates that there is no data but the indicated operations will still occur,

EXAMPLE 1 If the command implements PCR[2] in a SHA1 bank and a SHA256 bank, then an extend to PCR[2] will cause *eventData* to be hashed twice, once with SHA1 and once with SHA256. The SHA1 hash of *eventData* will be Extended to PCR[2] in the SHA1 bank and the SHA256 hash of *eventData* will be Extended to PCR[2] of the SHA256 bank.

On successful command completion, *digests* will contain the list of tagged digests of *eventData* that was computed in preparation for extending the data into the PCR. At the option of the TPM, the list may contain a digest for each bank, or it may only contain a digest for each bank in which *pcrHandle* is extant. If *pcrHandle* is TPM_RH_NULL, the TPM may return either an empty list or a digest for each bank.

EXAMPLE 2 Assume a TPM that implements a SHA1 bank and a SHA256 bank and that PCR[22] is only implemented in the SHA1 bank. If *pcrHandle* references PCR[22], then *digests* may contain either a SHA1 and a SHA256 digest or just a SHA1 digest.

[[PCR_Event]]

22.4 TPM2_PCR_Read

22.4.1 General Description

This command returns the values of all PCR specified in *pcrSelectionIn*.

The TPM will process the list of TPMS_PCR_SELECTION in *pcrSelectionIn* in order. Within each TPMS_PCR_SELECTION, the TPM will process the bits in the *pcrSelect* array in ascending PCR order (see TPM 2.0 Part 1, *Selecting Multiple PCR*). If a bit is SET, and the indicated PCR is present, then the TPM will add the digest of the PCR to the list of values to be returned in *pcrValues.*

The TPM will continue processing bits until all have been processed or until *pcrValues* would be too large to fit into the output buffer if additional values were added.

The returned *pcrSelectionOut* will have a bit SET in its *pcrSelect* structures for each value present in *pcrValues*.

The current value of the PCR Update Counter is returned in *pcrUpdateCounter*.

The returned list may be empty if none of the selected PCR are implemented.

NOTE If no PCR are returned from a bank, the selector for the bank will be present in *pcrSelectionOut*.

No authorization is required to read a PCR and any implemented PCR may be read from any locality.

22.5 TPM2_PCR_Allocate

22.5.1 General Description

This command is used to set the desired PCR allocation of PCR and algorithms. This command requires Platform Authorization.

The TPM will evaluate the request and, if sufficient memory is available for the requested allocation, the TPM will store the allocation request for use during the next _TPM_Init operation. The PCR allocation in place when this command is executed will be retained until the next _TPM_Init. If this command is received multiple times before a _TPM_Init, each one overwrites the previous stored allocation.

This command will only change the allocations of banks that are listed in *pcrAllocation*.

EXAMPLE 1 If a TPM supports SHA1 and SHA256, then it maintains an allocation for two banks (one of which could be empty). If *pcrAllocation* only has a selector for the SHA1 bank, then only the allocation of the SHA1 bank will be changed and the SHA256 bank will remain unchanged. To change the allocation of a TPM from 24 SHA1 PCR and no SHA256 PCR to 24 SHA256 PCR and no SHA1 PCR, the *pcrAllocation* would have to have two selections: one for the empty SHA1 bank and one for the SHA256 bank with 24 PCR.

If a bank is listed more than once, then the last selection in the *pcrAllocation* list is the one that the TPM will attempt to allocate.

NOTE 1 This does not mean to imply that *pcrAllocation.count* can exceed HASH_COUNT, the number of digests implemented in the TPM.

EXAMPLE 2 If HASH_COUNT is 2, *pcrAllocation* can specify SHA-256 twice, and the second one is used. However, if SHA_256 is specified three times, the unmarshaling may fail and the TPM may return an error.

This command shall not allocate more PCR in any bank than there are PCR attribute definitions. The PCR attribute definitions indicate how a PCR is to be managed – if it is resettable, the locality for update, etc. In the response to this command, the TPM returns the maximum number of PCR allowed for any bank.

When PCR are allocated, if DRTM_PCR is defined, the resulting allocation must have at least one bank with the D-RTM PCR allocated. If HCRTM_PCR is defined, the resulting allocation must have at least one bank with the HCRTM_PCR allocated. If not, the TPM returns TPM_RC_PCR.

The TPM may return TPM_RC_SUCCESS even though the request fails. This is to allow the TPM to return information about the size needed for the requested allocation and the size available. If the *sizeNeeded* parameter in the return is less than or equal to the *sizeAvailable* parameter, then the *allocationSuccess* parameter will be YES. Alternatively, if the request fails, The TPM may return TPM_RC_NO_RESULT.

NOTE 2 An example for this type of failure is a TPM that can only support one bank at a time and cannot support arbitrary distribution of PCR among banks.

After this command, TPM2_Shutdown() is only allowed to have a *startupType* equal to TPM_SU_CLEAR until after the next _TPM_Init.

NOTE 3 Even if this command does not cause the PCR allocation to change, the TPM cannot have its state saved. This is done in order to simplify the implementation. There is no need to optimize this command as it is not expected to be used more than once in the lifetime of the TPM (it can be used any number of times but there is no justification for optimization).

22.5.3 Detailed Actions

[[PCR_Allocate]]

22.6 TPM2_PCR_SetAuthPolicy

22.6.1 General Description

This command is used to associate a policy with a PCR or group of PCR. The policy determines the conditions under which a PCR may be extended or reset.

A policy may only be associated with a PCR that has been defined by a platform-specific specification as allowing a policy. If the TPM implementation does not allow a policy for *pcrNum*, the TPM shall return TPM_RC_VALUE.

A platform-specific specification may group PCR so that they share a common policy. In such case, a *pcrNum* that selects any of the PCR in the group will change the policy for all PCR in the group.

The policy setting is persistent and may only be changed by TPM2_PCR_SetAuthPolicy() or by TPM2_ChangePPS().

Before this command is first executed on a TPM or after TPM2_ChangePPS(), the access control on the PCR will be set to the default value defined in the platform-specific specification.

NOTE 1 It is expected that the typical default will be with the policy hash set to TPM_ALG_NULL and an Empty Buffer for the *authPolicy* value. This will allow an *EmptyAuth* to be used as the authorization value.

If the size of the data buffer in *authPolicy* is not the size of a digest produced by *hashAlg*, the TPM shall return TPM_RC_SIZE.

NOTE 2 If *hashAlg* is TPM_ALG_NULL, then the size is required to be zero.

This command requires platformAuth/platformPolicy.

NOTE 3 If the PCR is in multiple policy sets, the policy will be changed in only one set. The set that is changed will be implementation dependent.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

22.7 TPM2_PCR_SetAuthValue

22.7.1 General Description

This command changes the *authValue* of a PCR or group of PCR.

An *authValue* may only be associated with a PCR that has been defined by a platform-specific specification as allowing an authorization value. If the TPM implementation does not allow an authorization for *pcrNum*, the TPM shall return TPM_RC_VALUE. A platform-specific specification may group PCR so that they share a common authorization value. In such case, a *pcrNum* that selects any of the PCR in the group will change the *authValue* value for all PCR in the group.

The authorization setting is set to EmptyAuth on each STARTUP(CLEAR) or by TPM2_Clear(). The authorization setting is preserved by SHUTDOWN(STATE).

[[PCR_SetAuthValue]]

22.8 TPM2_PCR_Reset

22.8.1 General Description

If the attribute of a PCR allows the PCR to be reset and proper authorization is provided, then this command may be used to set the PCR in all banks to zero. The attributes of the PCR may restrict the locality that can perform the reset operation.

NOTE 1 The definition of TPMI_DH_PCR in TPM 2.0 Part 2 indicates that if pcrHandle is out of the allowed range for PCR, then the appropriate return value is TPM_RC_VALUE.

If *pcrHandle* references a PCR that cannot be reset, the TPM shall return TPM_RC_LOCALITY.

NOTE 2 TPM_RC_LOCALITY is returned because the reset attributes are defined on a per-locality basis.

22.9 _TPM_Hash_Start

22.9.1 Description

This indication from the TPM interface indicates the start of an H-CRTM measurement sequence. On receipt of this indication, the TPM will initialize an H-CRTM Event Sequence context.

If no object memory is available for creation of the sequence context, the TPM will flush the context of an object so that creation of the sequence context will always succeed.

A platform-specific specification may allow this indication before TPM2_Startup().

NOTE If this indication occurs after TPM2_Startup(), it is the responsibility of software to ensure that an object context slot is available or to deal with the consequences of having the TPM select an arbitrary object to be flushed. If this indication occurs before TPM2_Startup() then all context slots are available.

 Copyright © TCG 2006-2020

22.9.2 Detailed Actions

[[_TPM_Hash_Start]]

 Copyright © TCG 2006-2020

22.10 _TPM_Hash_Data

22.10.1 Description

This indication from the TPM interface indicates arrival of one or more octets of data that are to be included in the H-CRTM Event Sequence sequence context created by the _TPM_Hash_Start indication. The context holds data for each hash algorithm for each PCR bank implemented on the TPM.

If no H-CRTM Event Sequence context exists, this indication is discarded and no other action is performed.

 Copyright © TCG 2006-2020

22.10.2 Detailed Actions

[[_TPM_Hash_Data]]

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

22.11 _TPM_Hash_End

22.11.1 Description

This indication from the TPM interface indicates the end of the H-CRTM measurement. This indication is discarded and no other action performed if the TPM does not contain an H-CRTM Event Sequence context.

NOTE 1 An H-CRTM Event Sequence context is created by _TPM_Hash_Start().

If the H-CRTM Event Sequence occurs after TPM2_Startup(), the TPM will set all of the PCR designated in the platform-specific specifications as resettable by this event to the value indicated in the platform specific specification and increment *restartCount*. The TPM will then Extend the Event Sequence digest/digests into the designated D-RTM PCR (PCR[17]).

$$\text{PCR}[17][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(initial_value \,||\, \mathbf{H}_{hashAlg}(hash_data)) \quad (7)$$

where

$hashAlg$	hash algorithm associated with a bank of PCR
$initial_value$	initialization value specified in the platform-specific specification (should be 0…0)
$hash_data$	all the octets of data received in _TPM_Hash_Data indications

A _TPM_Hash_End indication that occurs after TPM2_Startup() will increment *pcrUpdateCounter* unless a platform-specific specification excludes modifications of PCR[DRTM] from causing an increment.

A platform-specific specification may allow an H-CRTM Event Sequence before TPM2_Startup(). If so, _TPM_Hash_End will complete the digest, initialize PCR[0] with a digest-size value of 4, and then extend the H-CRTM Event Sequence data into PCR[0].

$$\text{PCR}[0][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(0...04 \,||\, \mathbf{H}_{hashAlg}(hash_data)) \quad (8)$$

NOTE 2 The entire sequence of _TPM_Hash_Start, _TPM_Hash_Data, and _TPM_Hash_End are required to complete before TPM2_Startup() or the sequence will have no effect on the TPM.

NOTE 3 PCR[0] does not need to be updated according to (8) until the end of TPM2_Startup().

23 Enhanced Authorization (EA) Commands

23.1 Introduction

The commands in this clause 23 are used for policy evaluation. When successful, each command will update the *policySession→policyDigest* in a policy session context in order to establish that the authorizations required to use an object have been provided. Many of the commands will also modify other parts of a policy context so that the caller may constrain the scope of the authorization that is provided.

NOTE 1 Many of the terms used in this clause are described in detail in TPM 2.0 Part 1 and are not redefined in this clause.

The *policySession* parameter of the command is the handle of the policy session context to be modified by the command.

If the *policySession* parameter indicates a trial policy session, then the *policySession→policyDigest* will be updated and the indicated validations are not performed. However, any authorizations required to perform the policy command will be checked and dictionary attack logic invoked as necessary.

NOTE 2 If software is used to create policies, no authorization values are used. For example, TPM_PolicySecret requires an authorization in a trial policy session, but not in a policy calculation outside the TPM.

NOTE 3 A policy session is set to a trial policy by TPM2_StartAuthSession(*sessionType* = TPM_SE_TRIAL).

NOTE 4 Unless there is an unmarshaling error in the parameters of the command, these commands will return TPM_RC_SUCCESS when *policySession* references a trial session.

NOTE 5 Policy context other than the *policySession→policyDigest* may be updated for a trial policy but it is not required.

 Copyright © TCG 2006-2020

23.2 Signed Authorization Actions

23.2.1 Introduction

The TPM2_PolicySigned, TPM_PolicySecret, and TPM2_PolicyTicket commands use many of the same functions. This clause consolidates those functions to simplify the document and to ensure uniformity of the operations.

23.2.2 Policy Parameter Checks

These parameter checks will be performed when indicated in the description of each of the commands:

a) *nonceTPM* – If this parameter is not the Empty Buffer, and it does not match *policySession→nonceTPM*, then the TPM shall return TPM_RC_VALUE.

b) *expiration* – If this parameter is not zero, then:

   1) if *nonceTPM* is not an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and added to *policySession→startTime* to create the *timeout* value and proceed to c).

   2) If *nonceTPM* is an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and used as the *timeout* value and proceed to c).

   However, *timeout* can only be changed to a smaller value.

c) *timeout* – If *timeout* is less than the current value of *Time*, or the current *timeEpoch* is not the same as *policySession→timeEpoch, the* TPM shall return TPM_RC_EXPIRED

d) *cpHashA* – If this parameter is not an Empty Buffer

   NOTE 2 *cpHashA* is the hash of the command to be executed using this policy session in the authorization. The algorithm used to compute this hash is required to be the algorithm of the policy session.

   1) the TPM shall return TPM_RC_CPHASH if *policySession→cpHash* is set and the contents of *policySession→cpHash* are not the same as *cpHashA*; or

      NOTE 3 cpHash is the expected cpHash value held in the policy session context.

   2) the TPM shall return TPM_RC_SIZE if *cpHashA* is not the same size as *policySession→policyDigest*.

      NOTE 4 policySession→policyDigest is the size of the digest produced by the hash algorithm used to compute policyDigest.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

23.2.3 Policy Digest Update Function (PolicyUpdate())

This is the update process for *policySession→policyDigest* used by TPM2_PolicySigned(), TPM2_PolicySecret(), TPM2_PolicyTicket(), and TPM2_PolicyAuthorize(). The function prototype for the update function is:

$$\mathbf{PolicyUpdate}(commandCode, arg2, arg3) \quad (9)$$

where

$arg2$	a TPM2B_NAME
$arg3$	a TPM2B

These parameters are used to update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \;||\; commandCode \;||\; arg2.name) \quad (10)$$

followed by

$$policyDigest_{new+1} \coloneqq \mathbf{H}_{\mathrm{policyAlg}}(policyDigest_{new} \;||\; arg3.buffer) \quad (11)$$

where

$\mathbf{H}_{policyAlg}()$	the hash algorithm chosen when the policy session was started

NOTE 1 If *arg3* is a TPM2B_NAME, then *arg3.buffer* will actually be an *arg3.name*.

NOTE 2 The *arg2.size* and *arg3.size* fields are not included in the hashes.

NOTE 3 **PolicyUpdate**() uses two hash operations because *arg2* and *arg3* are variable-sized and the concatenation of *arg2* and *arg3* in a single hash could produce the same digest even though *arg2* and *arg3* are different. For example, arg2 = 1 2 3 and arg3 = 4 5 6 would produce the same digest as arg2 = 1 2 and arg3 = 3 4 5 6. Processing of the arguments separately in different Extend operation ensures that the digest produced by **PolicyUpdate**() will be different if *arg2* and *arg3* are different.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

23.2.4 Policy Context Updates

When a policy command modifies some part of the policy session context other than the *policySession→policyDigest*, the following rules apply.

- ***cpHash*** – this parameter may only be changed if it contains its initialization value (an Empty Buffer). If *cpHash* is not the Empty Buffer when a policy command attempts to update it, the TPM will return an error (TPM_RC_CPHASH) if the current and update values are not the same.
- ***timeOut*** – this parameter may only be changed to a smaller value. If a command attempts to update this value with a larger value (longer into the future), the TPM will discard the update value. This is not an error condition.
- ***commandCode*** – once set by a policy command, this value may not be changed except by TPM2_PolicyRestart(). If a policy command tries to change this to a different value, an error is returned (TPM_RC_POLICY_CC).
- ***pcrUpdateCounter*** – this parameter is updated by TPM2_PolicyPCR(). This value may only be set once during a policy. Each time TPM2_PolicyPCR() executes, it checks to see if *policySession→pcrUpdateCounter* has its default state, indicating that this is the first TPM2_PolicyPCR(). If it has its default value, then *policySession→pcrUpdateCounter* is set to the current value of *pcrUpdateCounter*. If *policySession→pcrUpdateCounter* does not have its default value and its value is not the same as *pcrUpdateCounter*, the TPM shall return TPM_RC_PCR_CHANGED.

  NOTE 1 If this parameter and *pcrUpdateCounter* are not the same, it indicates that PCR have changed since checked by the previous TPM2_PolicyPCR(). Since they have changed, the previous PCR validation is no longer valid.

- ***commandLocality*** – this parameter is the logical AND of all enabled localities. All localities are enabled for a policy when the policy session is created. TPM2_PolicyLocalities() selectively disables localities. Once use of a policy for a locality has been disabled, it cannot be enabled except by TPM2_PolicyRestart().
- ***isPPRequired*** – once SET, this parameter may only be CLEARed by TPM2_PolicyRestart().
- ***isAuthValueNeeded*** – once SET, this parameter may only be CLEARed by TPM2_PolicyPassword() or TPM2_PolicyRestart().
- ***isPasswordNeeded*** – once SET, this parameter may only be CLEARed by TPM2_PolicyAuthValue() or TPM2_PolicyRestart(),

NOTE 2 Both TPM2_PolicyAuthValue() and TPM2_PolicyPassword() change *policySession→policyDigest* in the same way. The different commands simply indicate to the TPM the format used for the *authValue* (HMAC or clear text). Both commands could be in the same policy. The final instance of these commands determines the format.

 Copyright © TCG 2006-2020

23.2.5 Policy Ticket Creation

For TPM2_PolicySigned() or TPM2_PolicySecret(), if the caller specified a negative value for *expiration*, then the TPM will return a ticket that includes a value indicating when the authorization expires. Otherwise, the TPM will return a NULL Ticket.

NOTE 1 If the *authHandle* in TPM2_PolicySecret() references a PIN Pass Index, then the command may succeed but a NULL Ticket will be returned.

The required computation for the digest in the authorization ticket is:

$$\mathbf{HMAC}_{contextAlg}(proof, (\text{TPM_ST_AUTH_xxx} \mathbin{||} cpHash \mathbin{||} policyRef \mathbin{||} authName \mathbin{||} timeout \mathbin{||} [timeEpoch] \mathbin{||} [resetCount])) \quad (12)$$

where

$\mathbf{HMAC}_{contextAlg}()$	an HMAC using the context integrity hash
$proof$	a TPM secret value associated with the hierarchy of the object associated with *authName*
TPM_ST_AUTH_xxx	either TPM_ST_AUTH_SIGNED or TPM_ST_AUTH_SECRET; used to ensure that the ticket is properly used
$cpHash$	optional hash of the authorized command
$policyRef$	optional reference to a policy value
$authName$	Name of the object that signed the authorization
$timeout$	implementation-specific value indicating when the authorization expires
$timeEpoch$	implementation-specific representation of the $timeEpoch$ at the time the ticket was created

NOTE 2 Not included if *timeout* is zero.

$resetCount$	implementation-specific representation of the TPM's *totalResetCount*

NOTE 3 Not included it *timeout* is zero or if *nonceTPM* was include in the authorization.

 Copyright © TCG 2006-2020

23.3 TPM2_PolicySigned

23.3.1 General Description

This command includes a signed authorization in a policy. The command ties the policy to a signing key by including the Name of the signing key in the *policyDigest*

If *policySession* is a trial session, the TPM will not check the signature and will update *policySession→policyDigest* as described in 23.2.3 as if a properly signed authorization was received, but no ticket will be produced.

If *policySession* is not a trial session, the TPM will validate *auth* and only perform the update if it is a valid signature over the fields of the command.

The authorizing entity will sign a digest of the authorization qualifiers: *nonceTPM*, *expiration*, *cpHashA*, and *policyRef*. The digest is computed as:

$$aHash \coloneqq \mathbf{H}_{authAlg}(nonceTPM \mid\mid expiration \mid\mid cpHashA \mid\mid policyRef) \quad (13)$$

where

$\mathbf{H}_{authAlg}()$ the hash associated with the auth parameter of this command

NOTE 1 Each signature and key combination indicates the scheme and each scheme has an associated hash.

$nonceTPM$ the nonceTPM parameter from the TPM2_StartAuthSession() response. If the authorization is not limited to this session, the size of this value is zero.

$expiration$ time limit on authorization set by authorizing object. This 32-bit value is set to zero if the expiration time is not being set.

$cpHashA$ digest of the command parameters for the command being approved using the hash algorithm of the policy session. Set to an Empty Digest if the authorization is not limited to a specific command.

NOTE 3 This is not the *cpHash* of this TPM2_PolicySigned() command.

$policyRef$ an opaque value determined by the authorizing entity. Set to the Empty Buffer if no value is present.

NOTE 4 The *nonceTPM*, *cpHashA*, and *policyRef* qualifiers used to compute *aHash* use the TPM2B buffer but do not prepend the size.

EXAMPLE The computation for an *aHash* if there are no restrictions is:

$$aHash \coloneqq \mathbf{H}_{authAlg}(00\ 00\ 00\ 00_{16})$$

which is the hash of an expiration time of zero.

The *aHash* is signed by the key associated with a key whose handle is *authObject*. The signature and signing parameters are combined to create the *auth* parameter.

The TPM will perform the parameter checks listed in 23.2.2

If the parameter checks succeed, the TPM will construct a test digest (*tHash*) over the provided parameters using the same formulation as shown in equation (13) above.

If *tHash* does not match the digest of the signed *aHash,* then the authorization fails and the TPM shall return TPM_RC_POLICY_FAIL and make no change to *policySession→policyDigest*.

 Copyright © TCG 2006-2020

When all validations have succeeded, *policySession→policyDigest* is updated by **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(\text{TPM_CC_PolicySigned}, authObject{\rightarrow}Name, policyRef) \tag{14}$$

authObject→Name is a TPM2B_NAME. *policySession* is updated as described in 23.2.4. The TPM will optionally produce a ticket as described in 23.2.5.

Authorization to use *authObject* is not required.

 Copyright © TCG 2006-2020

23.3.2 Command and Response

Table 124 — TPM2_PolicySigned Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit, encrypt, or decrypt session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_PolicySigned
TPMI_DH_OBJECT	authObject	handle for a key that will validate the signature Auth Index: None
TPMI_SH_POLICY	policySession	handle for the policy session being extended Auth Index: None
TPM2B_NONCE	nonceTPM	the policy nonce for the session This can be the Empty Buffer.
TPM2B_DIGEST	cpHashA	digest of the command parameters to which this authorization is limited This is not the *cpHash* for this command but the *cpHash* for the command to which this policy session will be applied. If it is not limited, the parameter will be the Empty Buffer.
TPM2B_NONCE	policyRef	a reference to a policy relating to the authorization – may be the Empty Buffer Size is limited to be no larger than the nonce size supported on the TPM.
INT32	expiration	time when authorization will expire, measured in seconds from the time that *nonceTPM* was generated If *expiration* is non-negative, a NULL Ticket is returned. See 23.2.5.
TPMT_SIGNATURE	auth	signed authorization (not optional)

Table 125 — TPM2_PolicySigned Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_TIMEOUT	timeout	implementation-specific time value, used to indicate to the TPM when the ticket expires NOTE If *policyTicket* is a NULL Ticket, then this shall be the Empty Buffer.
TPMT_TK_AUTH	policyTicket	produced if the command succeeds and *expiration* in the command was non-zero; this ticket will use the TPMT_ST_AUTH_SIGNED structure tag. See 23.2.5

23.3.3 Detailed Actions

[[PolicySigned]]

23.4 TPM2_PolicySecret

23.4.1 General Description

This command includes a secret-based authorization to a policy. The caller proves knowledge of the secret value using an authorization session using the *authValue* associated with *authHandle*. A password session, an HMAC session, or a policy session containing TPM2_PolicyAuthValue() or TPM2_PolicyPassword() will satisfy this requirement.

If a policy session is used and use of the *authValue* of *authHandle* is not required, the TPM will return TPM_RC_MODE. That is, the session for *authHandle* must have either *isAuthValueNeeded* or *isPasswordNeeded* SET.

The secret is the *authValue* of the entity whose handle is *authHandle,* which may be any TPM entity with a handle and an associated *authValue*. This includes the reserved handles (for example, Platform, Storage, and Endorsement), NV Indexes, and loaded objects. *authEntity* is the entity referenced by *authHandle*. If *authEntity* references an Ordinary object, it must have *userWithAuth* SET.

NOTE 1 The *userWithAuth* requirement permits the implementation to use common authorization code.

If *authEntity* references a non-PIN Index. TPMA_NV_AUTHREAD is required to be SET in the Index. If *authEntity* references an NV PIN index, TPMA_NV_WRITTEN is required to be SET and *pinCount* must be less than *pinLimit*.

NOTE 2 The authorization value for a hierarchy cannot be used in this command if the hierarchy is disabled.

If the authorization check fails, then the normal dictionary attack logic is invoked.

If the authorization provided by the authorization session is valid, the command parameters are checked as described in 23.2.2.

When all validations have succeeded, *policySession→policyDigest* is updated by **PolicyUpdate**() (see 23.2.3).

$$\textbf{PolicyUpdate}(\text{TPM_CC_PolicySecret}, authEntity{\rightarrow}Name, policyRef) \qquad (15)$$

authEntity→Name is a TPM2B_NAME. *policySession* is updated as described in 23.2.4. The TPM will optionally produce a ticket as described in 23.2.5.

If the session is a trial session, *policySession→policyDigest* is updated if the authorization is valid.

NOTE 2 If an HMAC is used to convey the authorization, a separate session is needed for the authorization. Because the HMAC in that authorization will include a nonce that prevents replay of the authorization, the value of the *nonceTPM* parameter in this command is limited. It is retained mostly to provide processing consistency with TPM2_PolicySigned().

23.5 TPM2_PolicyTicket

23.5.1 General Description

This command is similar to TPM2_PolicySigned() except that it takes a ticket instead of a signed authorization. The ticket represents a validated authorization that had an expiration time associated with it.

The parameters of this command are checked as described in 23.2.2.

If the checks succeed, the TPM uses the *timeout*, *cpHashA*, *policyRef*, and *authName* to construct a ticket to compare with the value in *ticket*. If these tickets match, then the TPM will create a TPM2B_NAME (*objectName*) using *authName* and update the context of *policySession* by **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(commandCode, authName, policyRef) \tag{16}$$

If the structure tag of ticket is TPM_ST_AUTH_SECRET, then *commandCode* will be TPM_CC_PolicySecret. If the structure tag of ticket is TPM_ST_AUTH_SIGNED, then *commandCode* will be TPM_CC_PolicySIgned.

policySession is updated as described in 23.2.4.

23.6 TPM2_PolicyOR

23.6.1 General Description

This command allows options in authorizations without requiring that the TPM evaluate all of the options. If a policy may be satisfied by different sets of conditions, the TPM need only evaluate one set that satisfies the policy. This command will indicate that one of the required sets of conditions has been satisfied.

PolicySession→policyDigest is compared against the list of provided values. If the current *policySession→policyDigest* does not match any value in the list, the TPM shall return TPM_RC_VALUE. Otherwise, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then *policySession→policyDigest* is extended by the concatenation of TPM_CC_PolicyOR and the concatenation of all of the digests.

If *policySession* is a trial session, the TPM will assume that *policySession→policyDigest* matches one of the list entries and compute the new value of *policyDigest*.

The algorithm for computing the new value for *policyDigest* of *policySession* is:

a) Concatenate all the digest values in *pHashList*:

$$digests \coloneqq pHashList.digests[1].buffer \;||\; \ldots \;||\; pHashList.digests[n].buffer \qquad (17)$$

NOTE 1 The TPM will not return an error if the size of an entry is not the same as the size of the digest of the policy. However, that entry cannot match *policyDigest*.

b) Reset *policyDigest* to a Zero Digest.

c) Extend the command code and the hashes computed in step a) above:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \;||\; \text{TPM_CC_PolicyOR} \;||\; digests) \qquad (18)$$

NOTE 2 The computation in b) and c) above is equivalent to:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(0\ldots0 \;||\; \text{TPM_CC_PolicyOR} \;||\; digests)$$

A TPM shall support a list with at least eight tagged digest values.

NOTE 3 If policies are to be portable between TPMs, then they should not use more than eight values.

23.6.3 Detailed Actions

[[PolicyOR]]

23.7 TPM2_PolicyPCR

23.7.1 General Description

This command is used to cause conditional gating of a policy based on PCR. This command together with TPM2_PolicyOR() allows one group of authorizations to occur when PCR are in one state and a different set of authorizations when the PCR are in a different state.

The TPM will modify the *pcrs* parameter so that bits that correspond to unimplemented PCR are CLEAR. If *policySession* is not a trial policy session, the TPM will use the modified value of pcrs to select PCR values to hash according to TPM 2.0 Part 1, *Selecting Multiple PCR.* The hash algorithm of the policy session is used to compute a digest (*digestTPM*) of the selected PCR. If *pcrDigest* does not have a length of zero, then it is compared to *digestTPM*; and if the values do not match, the TPM shall return TPM_RC_VALUE and make no change to *policySession→policyDigest*. If the values match, or if the length of *pcrDigest* is zero, then *policySession→policyDigest* is extended by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \,||\, \text{TPM_CC_PolicyPCR} \,||\, pcrs \,||\, digestTPM) \qquad (19)$$

where

$pcrs$	the pcrs parameter with bits corresponding to unimplemented PCR set to 0
$digestTPM$	the digest of the selected PCR using the hash algorithm of the policy session

NOTE 1 If the caller provides the expected PCR value, the intention is that the policy evaluation stop at that point if the PCR do not match. If the caller does not provide the expected PCR value, then the validity of the settings will not be determined until an attempt is made to use the policy for authorization. If the policy is constructed such that the PCR check comes before user authorization checks, this early termination would allow software to avoid unnecessary prompts for user input to satisfy a policy that would fail later due to incorrect PCR values.

After this command completes successfully, the TPM shall return TPM_RC_PCR_CHANGED if the policy session is used for authorization and the PCR are not known to be correct.

The TPM uses a "generation" number (*pcrUpdateCounter*) that is incremented each time PCR are updated (unless the PCR being changed is specified not to cause a change to this counter). The value of this counter is stored in the policy session context (*policySession→pcrUpdateCounter*) when this command is executed. When the policy is used for authorization, the current value of the counter is compared to the value in the policy session context and the authorization will fail if the values are not the same.

When this command is executed, *policySession→pcrUpdateCounter* is checked to see if it has been previously set (in the reference implementation, it has a value of zero if not previously set). If it has been set, it will be compared with the current value of *pcrUpdateCounter* to determine if any PCR changes have occurred. If the values are different, the TPM shall return TPM_RC_PCR_CHANGED.

NOTE 2 Since the pcrUpdateCounter is updated if any PCR is extended (except those specified not to do so), this means that the command will fail even if a PCR not specified in the policy is updated. This is an optimization for the purposes of conserving internal TPM memory. This would be a rare occurrence, and, if this should occur, the policy could be reset using the TPM2_PolicyRestart command and rerun.

If *policySession→pcrUpdateCounter* has not been set, then it is set to the current value of *pcrUpdateCounter*.

If this command is used for a trial *policySession*, *policySession→policyDigest* will be updated using the values from the command rather than the values from a digest of the TPM PCR. If the caller does not provide PCR settings (*pcrDigest* has a length of zero), the TPM may (and it is preferred to) use the

 Copyright © TCG 2006-2020

current TPM PCR settings (*digestTPM)* in the calculation for the new *policyDigest*. The TPM may return an error if the caller does not provide a PCR digest for a trial policy session but this is not the preferred behavior.

The TPM will not check any PCR and will compute:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyPCR} \mathbin{||} pcrs \mathbin{||} pcrDigest) \tag{20}$$

In this computation, pcrs is the input parameter without modification.

NOTE 3 The pcrs parameter is expected to match the configuration of the TPM for which the policy is being computed which may not be the same as the TPM on which the trial policy is being computed.

NOTE 4 Although no PCR are checked in a trial policy session, *pcrDigest* is expected to correspond to some useful PCR values. It is legal, but pointless, to have the TPM aid in calculating a *policyDigest* corresponding to PCR values that are not useful in practice.

23.8 TPM2_PolicyLocality

23.8.1 General Description

This command indicates that the authorization will be limited to a specific locality.

policySession→commandLocality is a parameter kept in the session context. When the policy session is started, this parameter is initialized to a value that allows the policy to apply to any locality.

If *locality* has a value greater than 31, then an extended locality is indicated. For an extended locality, the TPM will validate that *policySession→commandLocality* has not previously been set or that the current value of *policySession→commandLocality* is the same as *locality* (TPM_RC_RANGE).

When *locality* is not an extended locality, the TPM will validate that the *policySession→commandLocality* is not set to an extended locality value (TPM_RC_RANGE). If not the TPM will disable any locality not SET in the *locality* parameter. If the result of disabling localities results in no locality being enabled, the TPM will return TPM_RC_RANGE.

If no error occurred in the validation of *locality*, *policySession→policyDigest* is extended with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyLocality} \mathbin{||} locality) \quad (21)$$

Then *policySession→commandLocality* is updated to indicate which localities are still allowed after execution of TPM2_PolicyLocality().

When the policy session is used to authorize a command, the authorization will fail if the locality used for the command is not one of the enabled localities in *policySession→commandLocality*.

23.8.3 Detailed Actions

[[PolicyLocality]]

23.9 TPM2_PolicyNV

23.9.1 General Description

This command is used to cause conditional gating of a policy based on the contents of an NV Index. It is an immediate assertion. The NV index is validated during the TPM2_PolicyNV() command, not when the session is used for authorization.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equations (22) and (23) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

An authorization session providing authorization to read the NV Index shall be provided.

If TPMA_NV_WRITTEN is not SET in the NV Index, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

operandA begins at *offset* into the NV index contents and has a size equal to the size of *operandB*. The TPM will perform the indicated arithmetic check using *operandA* and *operandB*. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession→policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args \coloneqq \mathbf{H}_{policyAlg}(operandB.buffer \mid\mid offset \mid\mid operation) \quad (22)$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$operandB$	the value used for the comparison
$offset$	offset from the start of the NV Index data to start the comparison
$operation$	the operation parameter indicating the comparison being performed

The value of args and the Name of the NV Index are extended to *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyNV} \mid\mid args \mid\mid nvIndex{\rightarrow}Name) \quad (23)$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$args$	value computed in equation (22)
$nvIndex{\rightarrow}Name$	the Name of the NV Index

The signed arithmetic operations are performed using twos-compliment.

Magnitude comparisons assume that the octet at offset zero in the referenced NV location and in *operandB* contain the most significant octet of the data.

23.10 TPM2_PolicyCounterTimer

23.10.1 General Description

This command is used to cause conditional gating of a policy based on the contents of the TPMS_TIME_INFO structure.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equations (24) and (25) below and return TPM_RC_SUCCESS. It will not perform any validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

The TPM will perform the indicated arithmetic check on the indicated portion of the TPMS_TIME_INFO structure. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession→policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args \coloneqq \mathbf{H}_{policyAlg}(operandB.buffer \mid\mid offset \mid\mid operation) \tag{24}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$operandB.buffer$	the value used for the comparison
$offset$	offset from the start of the TPMS_TIME_INFO structure at which the comparison starts
$operation$	the operation parameter indicating the comparison being performed

NOTE There is no security related reason for the double hash.

The value of *args* is extended to *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyCounterTimer} \mid\mid args) \tag{25}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$args$	value computed in equation (24)

The signed arithmetic operations are performed using twos-compliment. The indicated portion of the TPMS_TIME_INFO structure begins at *offset* and has a length of *operandB.size*. If the number of octets to be compared overflows the TPMS_TIME_INFO structure, the TPM returns TPM_RC_RANGE. If *offset* is greater than the size of the marshaled TPMS_TIME_INFO structure, the TPM returns TPM_RC_VALUE. The structure is marshaled into its canonical form with no padding. The TPM does not check for alignment of the offset with a TPMS_TIME_INFO structure member.

Magnitude comparisons assume that the octet at offset zero in the referenced location and in *operandB* contain the most significant octet of the data.

[[PolicyCounterTimer]]

23.11 TPM2_PolicyCommandCode

23.11.1 General Description

This command indicates that the authorization will be limited to a specific command code.

If *policySession→commandCode* has its default value, then it will be set to *code.* If *policySession→commandCode* does not have its default value, then the TPM will return TPM_RC_VALUE if the two values are not the same.

If *code* is not implemented, the TPM will return TPM_RC_POLICY_CC.

If the TPM does not return an error, it will update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \,||\, \text{TPM_CC_PolicyCommandCode} \,||\, code) \qquad (26)$$

NOTE 1 If a previous TPM2_PolicyCommandCode() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *code* is the same.

NOTE 2 A TPM2_PolicyOR() would be used to allow an authorization to be used for multiple commands.

When the policy session is used to authorize a command, the TPM will fail the command if the *commandCode* of that command does not match *policySession→commandCode*.

This command, or TPM2_PolicyDuplicationSelect(), is required to enable the policy to be used for ADMIN role authorization.

EXAMPLE Before TPM2_Certify() can be executed, TPM2_PolicyCommandCode() with code set to TPM_CC_Certify is required.

23.12.3 Detailed Actions

[[PolicyPhysicalPresence]]

23.13 TPM2_PolicyCpHash

23.13.1 General Description

This command is used to allow a policy to be bound to a specific command and command parameters.

TPM2_PolicySigned(), TPM2_PolicySecret(), and TPM2_PolicyTIcket() are designed to allow an authorizing entity to execute an arbitrary command as the *cpHashA* parameter of those commands is not included in *policySession→policyDigest*. TPM2_PolicyCommandCode() allows the policy to be bound to a specific Command Code so that only certain entities may authorize specific command codes. This command allows the policy to be restricted such that an entity may only authorize a command with a specific set of parameters.

If *policySession→cpHash* is already set and not the same as *cpHashA*, then the TPM shall return TPM_RC_CPHASH. If *cpHashA* does not have the size of the *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE.

NOTE 1 If a previous TPM2_PolicyCpHash() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *cpHash* is the same.

If the *cpHashA* checks succeed, *policySession→cpHash* is set to *cpHashA* and *policySession→policyDigest* is updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyCpHash} \mathbin{||} cpHashA) \tag{28}$$

23.14 TPM2_PolicyNameHash

23.14.1 General Description

This command allows a policy to be bound to a specific set of TPM entities without being bound to the parameters of the command. This is most useful for commands such as TPM2_Duplicate() and for TPM2_PCR_Event() when the referenced PCR requires a policy.

The *nameHash* parameter should contain the digest of the Names associated with the handles to be used in the authorized command.

EXAMPLE For the TPM2_Duplicate() command, two handles are provided. One is the handle of the object being duplicated and the other is the handle of the new parent. For that command, *nameHash* would contain:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectHandle{\rightarrow}Name \mid\mid newParentHandle{\rightarrow}Name)$$

If *policySession→cpHash* is already set, the TPM shall return TPM_RC_CPHASH. If the size of *nameHash* is not the size of *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession→cpHash* is set to *nameHash*.

If this command completes successfully, the *cpHash* of the authorized command will not be used for validation. Only the digest of the Names associated with the handles in the command will be used.

NOTE 1 This allows the space normally used to hold *policySession→cpHash* to be used for *policySession→nameHash* instead.

The *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyNameHash} \mid\mid nameHash) \quad (29)$$

NOTE 2 This command can only be used with TPM2_PolicyAuthorize() or TPM2_PolicyAuthorizeNV. The owner of the object being duplicated provides approval for their object to be migrated to a specific new parent.

Without this approval, the Name of the Object would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity.

23.14.3 Detailed Actions

[[PolicyNameHash]]

23.15 TPM2_PolicyDuplicationSelect

23.15.1 General Description

This command allows qualification of duplication to allow duplication to a selected new parent.

If this command not used in conjunction with a PolicyAuthorize Command, then only the new parent is selected and *includeObject* should be CLEAR.

EXAMPLE When an object is created when the list of allowed duplication targets is known, the policy would be created with *includeObject* CLEAR.

NOTE 1 Only the new parent may be selected because, without TPM2_PolicyAuthorize(), the Name of the Object to be duplicated would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity (a PolicyAuthorize Command) in which case *includeObject* may be SET.

If used in conjunction with TPM2_PolicyAuthorize(), then the authorizer of the new policy has the option of selecting just the new parent or of selecting both the new parent and the duplication Object.

NOTE 2 If the authorizing entity for an TPM2_PolicyAuthorize() only specifies the new parent, then that authorization may be applied to the duplication of any number of other Objects. If the authorizing entity specifies both a new parent and the duplicated Object, then the authorization only applies to that pairing of Object and new parent.

If either *policySession→cpHash* or *policySession→nameHash* has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, *policySession→nameHash* will be set to:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectName.name \; || \; newParentName.name) \quad (30)$$

NOTE 3 It is allowed that policySesion→nameHash and policySession→cpHash share the same memory space.

NOTE 4 The Name in these equations uses Name.name, indicating that the UINT16 size is not included in the hash.

The *policySession→policyDigest* will be updated according to the setting of *includeObject*. If equal to YES, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \; || \; \text{TPM_CC_PolicyDuplicationSelect} \; || \; objectName.name \; || \; newParentName.name \; || \; includeObject) \quad (31)$$

If includeObject is NO, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \; || \; \text{TPM_CC_PolicyDuplicationSelect} \; || \; newParentName.name \; || \; includeObject) \quad (32)$$

NOTE 5 *policySession→nameHash* receives the digest of both Names so that the check performed in TPM2_Duplicate() may be the same regardless of which Names are included in *policySession→policyDigest*. This means that, when TPM2_PolicyDuplicationSelect() is executed, it is only valid for a specific pair of duplication object and new parent.

If the command succeeds, *policySession→commandCode* is set to TPM_CC_Duplicate.

NOTE 6 The normal use of this command is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allowed duplication to a specific new parent. The authorizing entity may want to limit the authorization so that the approval allows only a specific object to be duplicated to the new parent. In that case, the authorizing entity would approve the *policyDigest* of *equation* (31).

23.15.3 Detailed Actions

[[PolicyDuplicationSelect]]

23.16 TPM2_PolicyAuthorize

23.16.1 General Description

This command allows policies to change. If a policy were static, then it would be difficult to add users to a policy. This command lets a policy authority sign a new policy so that it may be used in an existing policy.

The authorizing entity signs a structure that contains

$$aHash \coloneqq \mathbf{H}_{aHashAlg}(approvedPolicy \mid\mid policyRef) \tag{33}$$

The *aHashAlg* is required to be the *nameAlg* of the key used to sign the *aHash*. The *aHash* value is then signed (symmetric or asymmetric) by *keySign*. That signature is then checked by the TPM in 20.1 TPM2_VerifySignature() which produces a ticket by

$$\mathbf{HMAC}(proof, (\text{TPM_ST_VERIFIED} \mid\mid aHash \mid\mid keySign{\rightarrow}Name)) \tag{34}$$

NOTE 1 The reason for the validation is because of the expectation that the policy will be used multiple times and it is more efficient to check a ticket than to load an object each time to check a signature.

The ticket is then used in TPM2_PolicyAuthorize() to validate the parameters.

The *keySign* parameter is required to be a valid object name using nameAlg other than TPM_ALG_NULL. If the first two octets of *keySign* are not a valid hash algorithm, the TPM shall return TPM_RC_HASH. If the remainder of the Name is not the size of the indicated digest, the TPM shall return TPM_RC_SIZE.

The TPM validates that the *approvedPolicy* matches the current value of *policySession→policyDigest* and if not, shall return TPM_RC_VALUE.

The TPM then validates that the parameters to TPM2_PolicyAuthorize() match the values used to generate the ticket. If so, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then it will update *policySession→policyDigest* with **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(\text{TPM_CC_PolicyAuthorize}, keySign, policyRef) \tag{35}$$

If the ticket is not valid, the TPM shall return TPM_RC_POLICY.

If *policySession* is a trial session, *policySession→policyDigest* is extended as if the ticket is valid without actual verification.

NOTE 2 The unmarshaling process requires that a proper TPMT_TK_VERIFIED be provided for *checkTicket* but it may be a NULL Ticket. A NULL ticket is useful in a trial policy, where the caller uses the TPM to perform policy calculations but does not have a valid authorization ticket.

[[PolicyAuthorize]]

23.17 TPM2_PolicyAuthValue

23.17.1 General Description

This command allows a policy to be bound to the authorization value of the authorized entity.

When this command completes successfully, *policySession→isAuthValueNeeded* is SET to indicate that the *authValue* will be included in *hmacKey* when the authorization HMAC is computed for the command being authorized using this session. Additionally, *policySession→isPasswordNeeded* will be CLEAR.

NOTE If a policy does not use this command, then the *hmacKey* for the authorized command would only use *sessionKey.* If *sessionKey* is not present, then the *hmacKey* is an Empty Buffer and no HMAC would be computed.

If successful, *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyAuthValue}) \quad (36)$$

23.17.3 Detailed Actions

[[PolicyAuthValue]]

23.18 TPM2_PolicyPassword

23.18.1 General Description

This command allows a policy to be bound to the authorization value of the authorized object.

When this command completes successfully, *policySession→isPasswordNeeded* is SET to indicate that *authValue* of the authorized object will be checked when the session is used for authorization. The caller will provide the *authValue* in clear text in the *hmac* parameter of the authorization. The comparison of *hmac* to *authValue* is performed as if the authorization is a password.

NOTE 1 The parameter field in the policy session where the authorization value is provided is called *hmac*. If TPM2_PolicyPassword() is part of the sequence, then the field will contain a password and not an HMAC.

If successful, *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyAuthValue}) \quad (37)$$

NOTE 2 This is the same extend value as used with TPM2_PolicyAuthValue so that the evaluation may be done using either an HMAC or a password with no change to the *authPolicy* of the object. The reason that two commands are present is to indicate to the TPM if the *hmac* field in the authorization will contain an HMAC or a password value.

When this command is successful, *policySession→isAuthValueNeeded* will be CLEAR.

 Copyright © TCG 2006-2020

23.20 TPM2_PolicyNvWritten

23.20.1 General Description

This command allows a policy to be bound to the TPMA_NV_WRITTEN attributes. This is a deferred assertion. Values are stored in the policy session context and checked when the policy is used for authorization.

If *policySession→checkNVWritten* is CLEAR, it is SET and *policySession→nvWrittenState* is set to *writtenSet*. If *policySession→checkNVWritten* is SET, the TPM will return TPM_RC_VALUE if *policySession→nvWrittenState* and *writtenSet* are not the same.

If the TPM does not return an error, it will update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyNvWritten} \mathbin{||} writtenSet) \quad (38)$$

When the policy session is used to authorize a command, the TPM will fail the command if *policySession→checkNVWritten* is SET and *nvIndex→attributes→TPMA_NV_WRITTEN does not match policySession→nvWrittenState.*

NOTE 1 A typical use case is a simple policy for the first write during manufacturing provisioning that would require TPMA_NV_WRITTEN CLEAR and a more complex policy for later use that would require TPMA_NV_WRITTEN SET.

NOTE 2 When an Index is written, it has a different authorization name than an Index that has not been written. It is possible to use this change in the NV Index to create a write-once Index.

23.20.3 Detailed Actions

[[PolicyNvWRitten]]

23.21 TPM2_PolicyTemplate

23.21.1 General Description

This command allows a policy to be bound to a specific creation template. This is most useful for an object creation command such as TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded().

The *templateHash* parameter should contain the digest of the template that will be required for the *inPublic* parameter of an Object creation command.

If *policySession→isTemplateHash* is SET and *policySession→cpHash* is not equal to *templateHash,* the TPM shall return TPM_RC_VALUE.

NOTE 1 Revision 01.38 of this specification permitted the TPM to return TPM_RC_CPHASH.

Otherwise, if *policySession→cpHash* is already set, the TPM shall return TPM_RC_CPHASH.

NOTE 2 Revision 01.38 of this specification permitted the TPM to return TPM_RC_VALUE.

If the size of *templateHash* is not the size of *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession→cpHash* is set to *templateHash*.

NOTE 3 The digest calculation includes the TPM2B buffer but not the TPM2B size.

If this command completes successfully, the *cpHash* of the authorized command will not be used for validation. Only the digest of the *inPublic* parameter will be used.

NOTE 4 This allows the space normally used to hold *policySession→cpHash* to be used for *policySession→templateHash* instead.

The *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyTemplate} \mathbin{||} templateHash) \qquad (39)$$

23.21.3 Detailed Actions

[[PolicyTemplate]]

23.22 TPM2_PolicyAuthorizeNV

23.22.1 General Description

This command provides a capability that is the equivalent of a revocable policy. With TPM2_PolicyAuthorize(), the authorization ticket never expires, so the authorization may not be withdrawn. With this command, the approved policy is kept in an NV Index location so that the policy may be changed as needed to render the old policy unusable.

NOTE 1 This command is useful for Objects but of limited value for other policies that are persistently stored in TPM NV, such as the OwnerPolicy.

An authorization session providing authorization to read the NV Index shall be provided.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equation (40) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

NOTE 2 If read access is controlled by policy, the policy should include a branch that authorizes a TPM2_PolicyAuthorizeNV().

If TPMA_NV_WRITTEN is not SET in the Index referenced by *nvIndex*, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

The *dataSize* of the NV Index referenced by *nvIndex* is required to be at least large enough to hold a properly formatted TPMT_HA (TPM_RC_INSUFFICIENT).

NOTE 3 A TPMT_HA contains a TPM_ALG_ID followed a digest that is consistent in size with the hash algorithm indicated by the TPM_ALG_ID.

It is an error (TPM_RC_HASH) if the first two octets of the Index are not a TPM_ALG_ID for a hash algorithm implemented on the TPM or if the indicated hash algorithm does not match *policySession→authHash*.

NOTE 4 The TPM_ALG_ID is stored in the first two octets in big endian format.

The TPM will compare *policySession→policyDigest* to the contents of the NV Index, starting at the first octet after the TPM_ALG_ID (the third octet) and return TPM_RC_VALUE if they are not the same.

NOTE 5 If the Index does not contain enough bytes for the compare, then TPM_RC_INSUFFICENT is generated as indicated above.

NOTE 6 The *dataSize* of the Index may be larger than is required for this command. This permits the Index to include metadata.

If the comparison is successful, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then it will update *policySession→policyDigest* with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyAuthorizeNV} \mathbin{||} nvIndex{\rightarrow}Name) \quad (40)$$

23.22.3 Detailed Actions

[[PolicyAuthorizeNV]]

24 Hierarchy Commands

24.1 TPM2_CreatePrimary

24.1.1 General Description

This command is used to create a Primary Object under one of the Primary Seeds or a Temporary Object under TPM_RH_NULL. The command uses a TPM2B_PUBLIC as a template for the object to be created. The size of the *unique* field shall not be checked for consistency with the other object parameters. The command will create and load a Primary Object. The sensitive area is not returned.

NOTE 1 Since the sensitive data is not returned, the key cannot be reloaded. It can either be made persistent or it can be recreated.

NOTE 2 For interoperability, the *unique* field should not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail.

NOTE 3 An Empty Buffer is a legal *unique* field value.

EXAMPLE 1 A TPM_ALG_RSA object with a *keyBits* of 2048 in the objects parameters should have a *unique* field that is no larger than 256 bytes.

EXAMPLE 2 A TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object should have a *unique* field this is no larger than the digest produced by the object's *nameAlg*.

Any type of object and attributes combination that is allowed by TPM2_Create() may be created by this command. The constraints on templates and parameters are the same as TPM2_Create() except that a Primary Storage Key and a Temporary Storage Key are not constrained to use the algorithms of their parents.

For setting of the attributes of the created object, *fixedParent*, *fixedTPM*, decrypt, and restricted are implied to be SET in the parent (a Permanent Handle). The remaining attributes are implied to be CLEAR.

The TPM will derive the object from the Primary Seed indicated in *primaryHandle* using an approved KDF. All of the bits of the template are used in the creation of the Primary Key. Methods for creating a Primary Object from a Primary Seed are described in TPM 2.0 Part 1 and implemented in TPM 2.0 Part 4.

If this command is called multiple times with the same *inPublic* parameter, *inSensitive.data*, and Primary Seed, the TPM shall produce the same Primary Object.

NOTE 4 If the Primary Seed is changed, the Primary Objects generated with the new seed shall be statistically unique even if the parameters of the call are the same.

This command requires authorization. Authorization for a Primary Object attached to the Platform Primary Seed (PPS) shall be provided by *platformAuth* or *platformPolicy*. Authorization for a Primary Object attached to the Storage Primary Seed (SPS) shall be provided by *ownerAuth* or *ownerPolicy*. Authorization for a Primary Key attached to the Endorsement Primary Seed (EPS) shall be provided by *endorsementAuth* or *endorsementPolicy*.

24.2 TPM2_HierarchyControl

24.2.1 General Description

This command enables and disables use of a hierarchy and its associated NV storage. The command allows *phEnable*, *phEnableNV*, *shEnable*, and *ehEnable* to be changed when the proper authorization is provided.

This command may be used to CLEAR *phEnable* and *phEnableNV* if *platformAuth/platformPolicy* is provided. *phEnable* may not be SET using this command.

This command may be used to CLEAR *shEnable* if either *platformAuth/platformPolicy* or *ownerAuth/ownerPolicy* is provided. *shEnable* may be SET if *platformAuth*/*platformPolicy* is provided.

This command may be used to CLEAR *ehEnable* if either *platformAuth*/*platformPolicy* or *endorsementAuth*/*endorsementPolicy* is provided. *ehEnable* may be SET if *platformAuth*/*platformPolicy* is provided.

When this command is used to CLEAR *phEnable*, *shEnable*, or *ehEnable*, the TPM will disable use of any persistent entity associated with the disabled hierarchy and will flush any transient objects associated with the disabled hierarchy.

When this command is used to CLEAR *shEnable,* the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE CLEAR (indicating that the NV Index was defined using Owner Authorization). As long as *shEnable* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE CLEAR.

When this command is used to CLEAR *phEnableNV*, the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE SET (indicating that the NV Index was defined using Platform Authorization). As long as *phEnableNV* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE SET.

24.2.3 Detailed Actions

[[HierarchyControl]]

24.3 TPM2_SetPrimaryPolicy

24.3.1 General Description

This command allows setting of the authorization policy for the lockout (*lockoutPolicy*), the platform hierarchy (*platformPolicy*), the storage hierarchy (*ownerPolicy*), and the endorsement hierarchy (*endorsementPolicy*). On TPMs implementing Authenticated Countdown Timers (ACT), this command may also be used to set the authorization policy for an ACT.

The command requires an authorization session. The session shall use the current *authValue* or satisfy the current *authPolicy* for the referenced hierarchy, or the ACT.

The policy that is changed is the policy associated with *authHandle*.

If the enable associated with *authHandle* is not SET, then the associated authorization values (*authValue* or *authPolicy*) may not be used, and the TPM returns TPM_RC_HIERARCHY.

When *hashAlg* is not TPM_ALG_NULL, if the size of *authPolicy* is not consistent with the hash algorithm, the TPM returns TPM_RC_SIZE.

24.4 TPM2_ChangePPS

24.4.1 General Description

This replaces the current platform primary seed (PPS) with a value from the RNG and sets *platformPolicy* to the default initialization value (the Empty Buffer).

NOTE 1 A policy that is the Empty Buffer can match no policy.

NOTE 2 Platform Authorization is not changed.

All resident transient and persistent objects in the Platform hierarchy are flushed.

Saved contexts in the Platform hierarchy that were created under the old PPS will no longer be able to be loaded.

The policy hash algorithm for PCR is reset to TPM_ALG_NULL.

This command does not clear any NV Index values.

NOTE 3 Index values belonging to the Platform are preserved because the indexes may have configuration information that will be the same after the PPS changes. The Platform may remove the indexes that are no longer needed using TPM2_NV_UndefineSpace().

This command requires Platform Authorization.

24.4.2 Command and Response

24.4.3 Detailed Actions

[[ChangePPS]]

24.5 TPM2_ChangeEPS

24.5.1 General Description

This replaces the current endorsement primary seed (EPS) with a value from the RNG and sets the Endorsement hierarchy controls to their default initialization values: *ehEnable* is SET, *endorsementAuth* and *endorsementPolicy* are both set to the Empty Buffer. It will flush any resident objects (transient or persistent) in the Endorsement hierarchy and not allow objects in the hierarchy associated with the previous EPS to be loaded.

NOTE In the reference implementation, *ehProof* is a non-volatile value from the RNG. It is allowed that the *ehProof* be generated by a KDF using both the EPS and SPS as inputs. If generated with a KDF, the ehProof can be generated on an as-needed basis or made a non-volatile value.

This command requires Platform Authorization.

24.5.3 Detailed Actions

[[ChangeEPS]]

24.6 TPM2_Clear

24.6.1 General Description

This command removes all TPM context associated with a specific Owner.

The clear operation will:

- flush resident objects (persistent and volatile) in the Storage and Endorsement hierarchies;
- delete any NV Index with TPMA_NV_PLATFORMCREATE == CLEAR;
- change the storage primary seed (SPS) to a new value from the TPM's random number generator (RNG),
- change *shProof* and *ehProof*,

NOTE 1 The proof values may be set from the RNG or derived from the associated new Primary Seed. If derived from the Primary Seeds, the derivation of *ehProof* shall use both the SPS and EPS. The computation shall use the SPS as an HMAC key and the derived value may then be a parameter in a second HMAC in which the EPS is the HMAC key. The reference design uses values from the RNG.

- SET *shEnable* and *ehEnable*;
- set *ownerAuth*, *endorsementAuth*, and *lockoutAuth* to the Empty Buffer;
- set *ownerPolicy, endorsementPolicy,* and *lockoutPolicy* to the Empty Buffer;
- set *Clock* to zero;
- set *resetCount* to zero;
- set *restartCount* to zero; and
- set *Safe* to YES.
- increment *pcrUpdateCounter*

NOTE 2 This permits an application to create a policy session that is invalidated on TPM2_Clear. The policy needs, ideally as the first term, TPM2_PolicyPCR(). The session is invalidated even if the PCR selection is empty.

This command requires Platform Authorization or Lockout Authorization. If TPM2_ClearControl() has disabled this command, the TPM shall return TPM_RC_DISABLED.

If this command is authorized using *lockoutAuth*, the HMAC in the response shall use the new *lockoutAuth* value (that is, the Empty Buffer) when computing the response HMAC.

24.6.3 Detailed Actions

[[Clear]]

24.7 TPM2_ClearControl

24.7.1 General Description

TPM2_ClearControl() disables and enables the execution of TPM2_Clear().

The TPM will SET the TPM's TPMA_PERMANENT.*disableClear* attribute if *disable* is YES and will CLEAR the attribute if *disable* is NO. When the attribute is SET, TPM2_Clear() may not be executed.

NOTE This is to simplify the logic of TPM2_Clear(). TPM2_ClearControl() can be called using Platform Authorization to CLEAR the *disableClear* attribute and then execute TPM2_Clear().

Lockout Authorization may be used to SET *disableClear* but not to CLEAR it.

Platform Authorization may be used to SET or CLEAR *disableClear*.

24.8 TPM2_HierarchyChangeAuth

24.8.1 General Description

This command allows the authorization secret for a hierarchy or lockout to be changed using the current authorization value as the command authorization.

If *authHandle* is TPM_RH_PLATFORM, then *platformAuth* is changed. If *authHandle* is TPM_RH_OWNER, then o*wnerAuth* is changed. If *authHandle* is TPM_RH_ENDORSEMENT, then e*ndorsementAuth* is changed. If *authHandle* is TPM_RH_LOCKOUT, then *lockoutAuth* is changed. The HMAC in the response shall use the new authorization value when computing the response HMAC.

If *authHandle* is TPM_RH_PLATFORM, then Physical Presence may need to be asserted for this command to succeed (see 26.2, *TPM2_PP_Commands*).

The authorization value may be no larger than the digest produced by the hash algorithm used for context integrity.

EXAMPLE If SHA384 is used in the computation of the integrity values for saved contexts, then the largest authorization value is 48 octets.

24.8.3 Detailed Actions

[[HierarchyChangeAuth]]

25 Dictionary Attack Functions

25.1 Introduction

A TPM is required to have support for logic that will help prevent a dictionary attack on an authorization value. The protection is provided by a counter that increments when a password authorization or an HMAC authorization fails. When the counter reaches a predefined value, the TPM will not accept, for some time interval, further requests that require authorization and the TPM is in Lockout mode. While the TPM is in Lockout mode, the TPM will return TPM_RC_LOCKOUT if the command requires use of an object's or Index's *authValue* unless the authorization applies to an entry in the Platform hierarchy.

NOTE 1 Authorizations for objects and NV Index values in the Platform hierarchy are never locked out. However, a command that requires multiple authorizations will not be accepted when the TPM is in Lockout mode unless all of the authorizations reference objects and indexes in the Platform hierarchy.

If the TPM is continuously powered for the duration of *newRecoveryTime* and no authorization failures occur, the authorization failure counter will be decremented by one. This property is called "self-healing." Self-healing shall not cause the count of failed attempts to decrement below zero.

The count of failed attempts, the lockout interval, and self-healing interval are settable using TPM2_DictionaryAttackParameters(). The lockout parameters and the current value of the lockout counter can be read with TPM2_GetCapability().

Dictionary attack protection does not apply to an entity associated with a permanent handle (handle type == TPM_HT_PERMANENT) other than TPM_RH_LOCKOUT

25.2 TPM2_DictionaryAttackLockReset

25.2.1 General Description

This command cancels the effect of a TPM lockout due to a number of successive authorization failures. If this command is properly authorized, the lockout counter is set to zero.

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval (set using TPM2_DictionaryAttackParameters().

25.2.3 Detailed Actions

[[DictionaryAttackLockReset]]

 Copyright © TCG 2006-2020

25.3 TPM2_DictionaryAttackParameters

25.3.1 General Description

This command changes the lockout parameters.

The command requires Lockout Authorization.

The timeout parameters (*newRecoveryTime* and *lockoutRecovery*) indicate values that are measured with respect to the *Time* and not *Clock*.

NOTE Use of *Time* means that the TPM shall be continuously powered for the duration of a timeout.

If *newRecoveryTime* is zero, then DA protection is disabled. Authorizations are checked but authorization failures will not cause the TPM to enter lockout.

If *newMaxTries* is zero, the TPM will be in lockout and use of DA protected entities will be disabled.

If *lockoutRecovery* is zero, then the recovery interval is _TPM_Init followed by TPM2_Startup().

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval.

26 Miscellaneous Management Functions

26.1 Introduction

This clause contains commands that do not logically group with any other commands.

26.2 TPM2_PP_Commands

26.2.1 General Description

This command is used to determine which commands require assertion of Physical Presence (PP) in addition to *platformAuth*/*platformPolicy*.

This command requires that *auth* is TPM_RH_PLATFORM and that Physical Presence be asserted.

After this command executes successfully, the commands listed in *setList* will be added to the list of commands that require that Physical Presence be asserted when the handle associated with the authorization is TPM_RH_PLATFORM. The commands in *clearList* will no longer require assertion of Physical Presence in order to authorize a command.

If a command is not in either list, its state is not changed. If a command is in both lists, then it will no longer require Physical Presence (for example, *setList* is processed first).

Only commands with handle types of TPMI_RH_PLATFORM, TPMI_RH_PROVISION, TPMI_RH_CLEAR, or TPMI_RH_HIERARCHY can be gated with Physical Presence. If any other command is in either list, it is discarded.

When a command requires that Physical Presence be provided, then Physical Presence shall be asserted for either an HMAC or a Policy authorization.

NOTE 1 Physical Presence may be made a requirement of any policy.

NOTE 2 If the TPM does not implement this command, the command list is vendor specific. A platform-specific specification may require that the command list be initialized in a specific way.

TPM2_PP_Commands() always requires assertion of Physical Presence.

[[PP_Commands]]

26.3 TPM2_SetAlgorithmSet

26.3.1 General Description

This command allows the platform to change the set of algorithms that are used by the TPM. The *algorithmSet* setting is a vendor-dependent value.

If the changing of the algorithm set results in a change of the algorithms of PCR banks, then the TPM will need to be reset (_TPM_Init and TPM2_Startup(TPM_SU_CLEAR)) before the new PCR settings take effect. After this command executes successfully, if *startupType* in the next TPM2_Startup() is not TPM_SU_CLEAR, the TPM shall return TPM_RC_VALUE and may enter Failure mode.

Other than PCR, when an algorithm is no longer supported, the behavior of this command is vendor-dependent.

EXAMPLE Entities may remain resident. Persistent objects, transient objects, or sessions may be flushed. NV Indexes may be undefined. Policies may be erased.

NOTE The reference implementation does not have support for this command. In particular, it does not support use of this command to selectively disable algorithms. Proper support would require modification of the unmarshaling code so that each time an algorithm is unmarshaled, it would be verified as being enabled.

26.3.3 Detailed Actions

[[SetAlgorithmSet]]

27 Field Upgrade

27.1 Introduction

This clause contains the commands for managing field upgrade of the firmware in the TPM. The field upgrade scheme may be used for replacement or augmentation of the firmware installed in the TPM.

EXAMPLE 1 If an algorithm is found to be flawed, a patch of that algorithm might be installed using the firmware upgrade process. The patch might be a replacement of a portion of the code or a complete replacement of the firmware.

EXAMPLE 2 If an additional set of ECC parameters is needed, the firmware process may be used to add the parameters to the TPM data set.

The field upgrade process uses two commands (TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData()). TPM2_FieldUpgradeStart() validates that a signature on the provided digest is from the TPM manufacturer and that proper authorization is provided using *platformPolicy*.

NOTE 1 The *platformPolicy* for field upgraded is defined by the PM and may include requirements that the upgrade be signed by the PM or the TPM owner and include any other constraints that are desired by the PM.

If the proper authorization is given, the TPM will retain the signed digest and enter the Field Upgrade mode (FUM). While in FUM, the TPM will accept TPM2_FieldUpgradeData() commands. It may accept other commands if it is able to complete them using the previously installed firmware. Otherwise, it will return TPM_RC_UPGRADE.

Each block of the field upgrade shall contain the digest of the next block of the field upgrade data. That digest shall be included in the digest of the previous block. The digest of the first block is signed by the TPM manufacturer. That signature and first block digest are the parameters for TPM2_FieldUpgradeStart(). The digest is saved in the TPM as the required digest for the next field upgrade data block and as the identifier of the field upgrade sequence.

For each field upgrade data block that is sent to the TPM by TPM2_FieldUpgradeData(), the TPM shall validate that the digest matches the required digest and if not, shall return TPM_RC_VALUE. The TPM shall extract the digest of the next expected block and return that value to the caller, along with the digest of the first data block of the update sequence.

The system may attempt to abandon the firmware upgrade by using a zero-length buffer in TPM2_FieldUpdateData(). If the TPM is able to resume operation using the firmware present when the upgrade started, then the TPM will indicate that it has abandon the update by setting the digest of the next block to the Empty Buffer. If the TPM cannot abandon the update, it will return the expected next digest.

The system may also attempt to abandon the update because of a power interruption. If the TPM is able to resume normal operations, then it will respond normally to TPM2_Startup(). If the TPM is not able to resume normal operations, then it will respond to any command but TPM2_FieldUpgradeData() with TPM_RC_UPGRADE.

After a _TPM_Init, system software may not be able to resume the field upgrade that was in process when the power interruption occurred. In such case, the TPM firmware may be reset to one of two other values:

- the original firmware that was installed at the factory (“initial firmware”); or
- the firmware that was in the TPM when the field upgrade process started (“previous firmware”).

The TPM retains the digest of the first block for these firmware images and checks to see if the first block after _TPM_Init matches either of those digests. If so, the firmware update process restarts and the original firmware may be loaded.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

NOTE 2 The TPM is required to accept the previous firmware as either a vendor-provided update or as recovered from the TPM using TPM2_FirmwareRead().

When the last block of the firmware upgrade is loaded into the TPM (indicated to the TPM by data in the data block in a TPM vendor-specific manner), the TPM will complete the upgrade process. If the TPM is able to resume normal operations without a reboot, it will set the hash algorithm of the next block to TPM_ALG_NULL and return TPM_RC_SUCCESS. If a reboot is required, the TPM shall return TPM_RC_REBOOT in response to the last TPM2_FieldUpgradeData() and all subsequent TPM commands until a _TPM_Init is received.

NOTE 3 Because no additional data is allowed when the response code is not TPM_RC_SUCCESS, the TPM returns TPM_RC_SUCCESS for all calls to TPM2_FieldUpgradeData() except the last. In this manner, the TPM is able to indicate the digest of the next block. If a _TPM_Init occurs while the TPM is in FUM, the next block may be the digest for the first block of the original firmware. If it is not, then the TPM will not accept the original firmware until the next _TPM_Init when the TPM is in FUM.

During the field upgrade process, either the one specified in this clause or a vendor proprietary field upgrade process, the TPM should preserve:

- Primary Seeds;
- Hierarchy *authValue*, *authPolicy*, and *proof* values;
- Lockout *authValue* and authorization failure count values;
- PCR authValue and authPolicy values;
- NV Index allocations and contents;
- Persistent object allocations and contents; and
- Clock.

NOTE 4 A platform manufacturer may provide a means to change preserved data to accommodate a case where a field upgrade fixes a flaw that might have compromised TPM secrets.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

27.2 TPM2_FieldUpgradeStart

27.2.1 General Description

This command uses *platformPolicy* and a TPM Vendor Authorization Key to authorize a Field Upgrade Manifest.

If the signature checks succeed, the authorization is valid and the TPM will accept TPM2_FieldUpgradeData().

This signature is checked against the loaded key referenced by *keyHandle*. This key will have a Name that is the same as a value that is part of the TPM firmware data. If the signature is not valid, the TPM shall return TPM_RC_SIGNATURE.

NOTE A loaded key is used rather than a hard-coded key to reduce the amount of memory needed for this key data in case more than one vendor key is needed.

27.3 TPM2_FieldUpgradeData

27.3.1 General Description

This command will take the actual field upgrade image to be installed on the TPM. The exact format of *fuData* is vendor-specific. This command is only possible following a successful TPM2_FieldUpgradeStart(). If the TPM has not received a properly authorized TPM2_FieldUpgradeStart(), then the TPM shall return TPM_RC_FIELDUPGRADE.

The TPM will validate that the digest of *fuData* matches an expected value. If so, the TPM may buffer or immediately apply the update. If the digest of *fuData* does not match an expected value, the TPM shall return TPM_RC_VALUE.

27.4 TPM2_FirmwareRead

27.4.1 General Description

This command is used to read a copy of the current firmware installed in the TPM.

The presumption is that the data will be returned in reverse order so that the last block in the sequence would be the first block given to the TPM in case of a failure recovery. If the TPM2_FirmwareRead sequence completes successfully, then the data provided from the TPM will be sufficient to allow the TPM to recover from an abandoned upgrade of this firmware.

To start the sequence of retrieving the data, the caller sets *sequenceNumber* to zero. When the TPM has returned all the firmware data, the TPM will return the Empty Buffer as *fuData*.

The contents of *fuData* are opaque to the caller.

NOTE 1 The caller should retain the ordering of the update blocks so that the blocks sent to the TPM have the same size and inverse order as the blocks returned by a sequence of calls to this command.

NOTE 2 Support for this command is optional even if the TPM implements TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData().

28 Context Management

28.1 Introduction

Three of the commands in this clause (TPM2_ContextSave(), TPM2_ContextLoad(), and TPM2_FlushContext()) implement the resource management described in the "Context Management" clause in TPM 2.0 Part 1.

The fourth command in this clause (TPM2_EvictControl()) is used to control the persistence of loadable objects in TPM memory. Background for this command may be found in the "Owner and Platform Evict Objects" clause in TPM 2.0 Part 1.

28.2 TPM2_ContextSave

28.2.1 General Description

This command saves a session context, object context, or sequence object context outside the TPM.

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS.

NOTE This preclusion avoids complex issues of dealing with the same session in *handle* and in the session area. While it might be possible to provide specificity, it would add unnecessary complexity to the TPM and, because this capability would provide no application benefit, use of authorization sessions for audit or encryption is prohibited.

The TPM shall encrypt and integrity protect the TPM2B_CONTEXT_SENSITIVE *context* as described in the "Context Protections" clause in TPM 2.0 Part 1.

See the “Context Data” clause in TPM 2.0 Part 2 for a description of the *context* structure in the response.

28.2.3 Detailed Actions

[[ContextSave]]

28.3 TPM2_ContextLoad

28.3.1 General Description

This command is used to reload a context that has been saved by TPM2_ContextSave().

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in 28.2.1).

The TPM will return TPM_RC_HIERARCHY if the context is associated with a hierarchy that is disabled.

NOTE Contexts for authorization sessions and for sequence objects belong to the NULL hierarchy, which is never disabled.

See the "Context Data" clause in TPM 2.0 Part 2 for a description of the values in the *context* parameter.

If the integrity HMAC of the saved context is not valid, the TPM shall return TPM_RC_INTEGRITY.

The TPM shall perform a check on the decrypted context as described in the "Context Confidentiality Protection" clause of TPM 2.0 Part 1 and enter failure mode if the check fails.

28.4 TPM2_FlushContext

28.4.1 General Description

This command causes all context associated with a loaded object, sequence object, or session to be removed from TPM memory.

This command may not be used to remove a persistent object from the TPM. Use TPM2_EvictControl to remove a persistent object.

A session does not have to be loaded in TPM memory to have its context flushed. The saved session context associated with the indicated handle is invalidated. When flushing a session, the upper byte of the handle is ignored.

EXAMPLE A command to flush session handle 0x20000000 will flush session handle 0x03000000.

No sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in 28.2.1).

If the handle is for a Transient Object and the handle is not associated with a loaded object, then the TPM shall return TPM_RC_HANDLE.

If the handle is for an authorization session and the handle does not reference a loaded or active session, then the TPM shall return TPM_RC_HANDLE.

NOTE *flushHandle* is a parameter and not a handle. If it were in the handle area, the TPM would validate that the context for the referenced entity is in the TPM. When a TPM2_FlushContext references a saved session context, it is not necessary for the context to be in the TPM. When the *flushHandle* is in the parameter area, the TPM does not validate that associated context is actually in the TPM.

28.4.3 Detailed Actions

[[FlushContext]]

28.5 TPM2_EvictControl

28.5.1 General Description

This command allows certain Transient Objects to be made persistent or a persistent object to be evicted.

NOTE 1 A transient object is one that may be removed from TPM memory using either TPM2_FlushContext or TPM2_Startup(). A persistent object is not removed from TPM memory by TPM2_FlushContext() or TPM2_Startup().

If *objectHandle* is a Transient Object, then this call makes a persistent copy of the object and assigns *persistentHandle* to the persistent version of the object. If *objectHandle* is a persistent object, then the call evicts the persistent object. The call does not affect the transient object.

Before execution of TPM2_EvictControl code below, the TPM verifies that *objectHandle* references an object that is resident on the TPM and that *persistentHandle* is a valid handle for a persistent object.

NOTE 2 This requirement simplifies the unmarshaling code so that it only need check that *persistentHandle* is always a persistent object.

If *objectHandle* references a Transient Object:

a) The TPM shall return TPM_RC_ATTRIBUTES if
   1) it is in the hierarchy of TPM_RH_NULL,
   2) only the public portion of the object is loaded, or

      NOTE 3 This is for NV space efficiency. Loading an object whose private part is empty would unnecessarily consume NV resources.

   3) the *stClear* is SET in the object or in an ancestor key.
b) The TPM shall return TPM_RC_HIERARCHY if the object is not in the proper hierarchy as determined by *auth*.
   1) If *auth* is TPM_RH_PLATFORM, the proper hierarchy is the Platform hierarchy.
   2) If *auth* is TPM_RH_OWNER, the proper hierarchy is either the Storage or the Endorsement hierarchy.
c) The TPM shall return TPM_RC_RANGE if *persistentHandle* is not in the proper range as determined by *auth*.
   1) If *auth* is TPM_RH_OWNER, then *persistentHandle* shall be in the inclusive range of $81\ 00\ 00\ 00_{16}$ to $81\ 7F\ FF\ FF_{16}$.
   2) If *auth* is TPM_RH_PLATFORM, then *persistentHandle* shall be in the inclusive range of $81\ 80\ 00\ 00_{16}$ to $81\ FF\ FF\ FF_{16}$.

   NOTE 4 This separation permits the platform (the platform OEM) a range of indexes that will not interfere with indexes used by the TPM owner (the OS or applications).

d) The TPM shall return TPM_RC_NV_DEFINED if a persistent object exists with the same handle as *persistentHandle*.
e) The TPM shall return TPM_RC_NV_SPACE if insufficient space is available to make the object persistent.
f) The TPM shall return TPM_RC_NV_SPACE if execution of this command will prevent the TPM from being able to hold two transient objects of any kind.

 Copyright © TCG 2006-2020

NOTE 5 This requirement anticipates that a TPM may be implemented such that all TPM memory is non-volatile and not subject to endurance issues. In such case, there is no movement of an object between memory of different types and it is necessary that the TPM ensure that it is always possible for the management software to move objects to/from TPM memory in order to ensure that the objects required for command execution can be context restored.

g) If the TPM returns TPM_RC_SUCCESS, the object referenced by *objectHandle* will not be flushed and both *objectHandle* and *persistentHandle* may be used to access the object.

If *objectHandle* references a persistent object:

a) The TPM shall return TPM_RC_RANGE if *objectHandle* is not in the proper range as determined by *auth*. If *auth* is TPM_RC_OWNER, *objectHandle* shall be in the inclusive range of 81 00 00 00_{16} to 81 7F FF FF_{16}. If *auth* is TPM_RC_PLATFORM, *objectHandle* may be any valid persistent object handle.

b) If objectHandle is not the same value as persistentHandle, return TPM_RC_HANDLE.

c) If the TPM returns TPM_RC_SUCCESS, *objectHandle* will be removed from persistent memory and no longer be accessible.

NOTE 5 The persistent object is not converted to a transient object, as this would prevent the immediate revocation of an object by removing it from persistent memory.

29.1.3 Detailed Actions

[[ReadClock]]

29.2 TPM2_ClockSet

29.2.1 General Description

This command is used to advance the value of the TPM's *Clock*. The command will fail if *newTime* is less than the current value of *Clock* or if the new time is greater than FF FF 00 00 00 00 00 00_{16}. If both of these checks succeed, *Clock* is set to *newTime*. If either of these checks fails, the TPM shall return TPM_RC_VALUE and make no change to *Clock*.

NOTE This maximum setting would prevent *Clock* from rolling over to zero for approximately 8,000 years at the real time *Clock* update rate. If the *Clock* update rate was set so that TPM time was passing 33 percent faster than real time, it would still be more than 6,000 years before *Clock* would roll over to zero. Because *Clock* will not roll over in the lifetime of the TPM, there is no need for external software to deal with the possibility that *Clock* may wrap around.

If the value of *Clock* after the update makes the volatile and non-volatile versions of TPMS_CLOCK_INFO.*clock* differ by more than the reported update interval, then the TPM shall update the non-volatile version of TPMS_CLOCK_INFO.*clock* before returning.

This command requires Platform Authorization or Owner Authorization.

29.2.3 Detailed Actions

[[ClockSet]]

29.3 TPM2_ClockRateAdjust

29.3.1 General Description

This command adjusts the rate of advance of *Clock* and *Time* to provide a better approximation to real time.

The *rateAdjust* value is relative to the current rate and not the nominal rate of advance.

EXAMPLE 1 If this command had been called three times with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER and once with *rateAdjust* = TPM_CLOCK_COARSE_FASTER, the net effect will be as if the command had been called twice with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER.

The range of adjustment shall be sufficient to allow *Clock* and *Time* to advance at real time but no more. If the requested adjustment would make the rate advance faster or slower than the nominal accuracy of the input frequency, the TPM shall return TPM_RC_VALUE.

EXAMPLE 2 If the frequency tolerance of the TPM's input clock is +/-10 percent, then the TPM will return TPM_RC_VALUE if the adjustment would make *Clock* run more than 10 percent faster or slower than nominal. That is, if the input oscillator were nominally 100 megahertz (MHz), then 1 millisecond (ms) would normally take 100,000 counts. The update *Clock* should be adjustable so that 1 ms is between 90,000 and 110,000 counts.

The interpretation of “fine” and “coarse” adjustments is implementation-specific.

The nominal rate of advance for *Clock* and *Time* shall be accurate to within 15 percent. That is, with no adjustment applied, *Clock* and *Time* shall be advanced at a rate within 15 percent of actual time.

NOTE If the adjustments are incorrect, it will be possible to make the difference between advance of *Clock/Time* and real time to be as much as 1.15^2 or ~1.33.

Changes to the current *Clock* update rate adjustment need not be persisted across TPM power cycles.

30 Capability Commands

30.1 Introduction

The TPM has numerous values that indicate the state, capabilities, and properties of the TPM. These values are needed for proper management of the TPM. The TPM2_GetCapability() command is used to access these values.

TPM2_GetCapability() allows reporting of multiple values in a single call. The values are grouped according to type.

NOTE TPM2_TestParms()is used to determine if a TPM supports a particular combination of algorithm parameters

30.2 TPM2_GetCapability

30.2.1 General Description

This command returns various information regarding the TPM and its current state.

The *capability* parameter determines the category of data returned. The *property* parameter selects the first value of the selected category to be returned. If there is no property that corresponds to the value of *property*, the next higher value is returned, if it exists.

EXAMPLE 1 The list of handles of transient objects currently loaded in the TPM may be read one at a time. On the first read, set the property to TRANSIENT_FIRST and *propertyCount* to one. If a transient object is present, the lowest numbered handle is returned and *moreData* will be YES if transient objects with higher handles are loaded. On the subsequent call, use returned handle value plus 1 in order to access the next higher handle.

The *propertyCount* parameter indicates the number of capabilities in the indicated group that are requested. The TPM will return no more than the number of requested values (*propertyCount*) or until the last property of the requested type has been returned.

NOTE 1 The type of the capability is derived from a combination of *capability* and *property*.

NOTE 2 If the *property* selects an unimplemented property, the next higher implemented property is returned.

When all of the properties of the requested type have been returned, the *moreData* parameter in the response will be set to NO. Otherwise, it will be set to YES.

NOTE 3 The *moreData* parameter will be YES if there are more properties even if the requested number of capabilities has been returned.

The TPM is not required to return more than one value at a time. It is not required to provide the same number of values in response to subsequent requests.

EXAMPLE 2 A TPM may return 4 properties in response to a TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTY, *property* = TPM_PT_MANUFACTURER, *propertyCount* = 8) and for a latter request with the same parameters, the TPM may return as few as one and as many as 8 values.

When the TPM is in Failure mode, a TPM is required to allow use of this command for access of the following capabilities:

 Copyright © TCG 2006-2020

- TPM_PT_MANUFACTURER
- TPM_PT_VENDOR_STRING_1
- TPM_PT_VENDOR_STRING_2 (NOTE 4)
- TPM_PT_VENDOR_STRING_3 (NOTE 4)
- TPM_PT_VENDOR_STRING_4 (NOTE 4)
- TPM_PT_VENDOR_TPM_TYPE
- TPM_PT_FIRMWARE_VERSION_1
- TPM_PT_FIRMWARE_VERSION_2

NOTE 4 If the vendor string does not require one of these values, the property type does not need to exist.

A vendor may optionally allow the TPM to return other values.

If in Failure mode and a capability is requested that is not available in Failure mode, the TPM shall return no value.

EXAMPLE 3 Assume the TPM is in Failure mode and the TPM only supports reporting of the minimum required set of properties (the limited subset of TPML_TAGGED_TPM_PROPERTY values). If a TPM2_GetCapability is received requesting a capability that has a property type value greater than TPM_PT_FIRMWARE_VERSION_2, the TPM may return a zero length list with the moreData parameter set to NO or return the property TPM_PT_FIRMWARE_VERSION_2. If the property type is less than TPM_PT_MANUFACTURER, the TPM will return properties beginning with TPM_PT_MANUFACTURER.

In Failure mode, *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

The capability categories and the types of the return values are:

capability	***property***	**Return Type**
TPM_CAP_ALGS	TPM_ALG_ID(1)	TPML_ALG_PROPERTY
TPM_CAP_HANDLES	TPM_HANDLE	TPML_HANDLE
TPM_CAP_COMMANDS	TPM_CC	TPML_CCA
TPM_CAP_PP_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_AUDIT_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_PCRS	Reserved	TPML_PCR_SELECTION
TPM_CAP_TPM_PROPERTIES	TPM_PT	TPML_TAGGED_TPM_PROPERTY
TPM_CAP_PCR_PROPERTIES	TPM_PT_PCR	TPML_TAGGED_PCR_PROPERTY
TPM_CAP_ECC_CURVES	TPM_ECC_CURVE(1)	TPML_ECC_CURVE
TPM_CAP_AUTH_POLICIES (3)	TPM_HANDLE(2)	TPML_TAGGED_POLICY
TPM_CAP_ACT(4)	TPM_HANDLE(2)	TPML_ACT_DATA
TPM_CAP_VENDOR_PROPERTY	manufacturer specific	manufacturer-specific values

NOTES:
(1) The TPM_ALG_ID or TPM_ECC_CURVE is cast to a UINT32
(2) The TPM will return TPM_RC_VALUE if the handle does not reference the range for permanent handles.
(3) TPM_CAP_AUTH_POLICIES was added in revision 01.32.
(4) TPM_CAP_ACT was added in revision 01.56.

 Copyright © TCG 2006-2020

- TPM_CAP_ALGS – Returns a list of TPMS_ALG_PROPERTIES. Each entry is an algorithm ID and a set of properties of the algorithm.
- TPM_CAP_HANDLES – Returns a list of all of the handles within the handle range of the *property* parameter. The range of the returned handles is determined by the handle type (the most-significant octet (MSO) of the *property)*. Any of the defined handle types is allowed

EXAMPLE 4 If the MSO of *property* is TPM_HT_NV_INDEX, then the TPM will return a list of NV Index values.

EXAMPLE 5 If the MSO of property is TPM_HT_PCR, then the TPM will return a list of PCR.

- For this capability, use of TPM_HT_LOADED_SESSION and TPM_HT_SAVED_SESSION is allowed. Requesting handles with a handle type of TPM_HT_LOADED_SESSION will return handles for loaded sessions. The returned handle values will have a handle type of either TPM_HT_HMAC_SESSION or TPM_HT_POLICY_SESSION. If saved sessions are requested, all returned values will have the TPM_HT_HMAC_SESSION handle type because the TPM does not track the session type of saved sessions.

NOTE 5 TPM_HT_LOADED_SESSION and TPM_HT_HMAC_SESSION have the same value, as do TPM_HT_SAVED_SESSION and TPM_HT_POLICY_SESSION. It is not possible to request that the TPM return a list of loaded HMAC sessions without including the policy sessions.

- TPM_CAP_COMMANDS – Returns a list of the command attributes for all of the commands implemented in the TPM, starting with the TPM_CC indicated by the *property* parameter. If vendor specific commands are implemented, the vendor-specific command attribute with the lowest *commandIndex*, is returned after the non-vendor-specific (base) command.

NOTE 6 The type of the property parameter is a TPM_CC while the type of the returned list is TPML_CCA.

- TPM_CAP_PP_COMMANDS – Returns a list of all of the commands currently requiring Physical Presence for confirmation of platform authorization. The list will start with the TPM_CC indicated by *property*.
- TPM_CAP_AUDIT_COMMANDS – Returns a list of all of the commands currently set for command audit.
- TPM_CAP_PCRS – Returns the current allocation of PCR in a TPML_PCR_SELECTION. The *property* parameter shall be zero. The TPM will always respond to this command with the full PCR allocation and *moreData* will be NO.

  The TPML_PCR_SELECTION must include a TPMS_PCR_SELECTION for each PCR bank in which there is at least one allocated PCR. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented PCR bank. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented hash algorithm.
- TPM_CAP_TPM_PROPERTIES – Returns a list of tagged properties. The tag is a TPM_PT and the property is a 32-bit value. The properties are returned in groups. Each property group is on a 256-value boundary (that is, the boundary occurs when the TPM_PT is evenly divisible by 256). The TPM will only return values in the same group as the *property* parameter in the command.
- TPM_CAP_PCR_PROPERTIES – Returns a list of tagged PCR properties. The tag is a TPM_PT_PCR and the property is a TPMS_PCR_SELECT.

  The input command property is a TPM_PT_PCR (see TPM 2.0 Part 2 for PCR properties to be requested) that specifies the first property to be returned. If propertyCount is greater than 1, the list of properties begins with that property and proceeds in TPM_PT_PCR sequence.

  Each item in the list is a TPMS_PCR_SELECT structure that contains a bitmap of all PCR.

NOTE 7 A PCR index in all banks (all hash algorithms) has the same properties, so the hash algorithm is not specified here.

 Copyright © TCG 2006-2020

- TPM_CAP_TPM_ECC_CURVES – Returns a list of ECC curve identifiers currently available for use in the TPM.
- TPM_CAP_AUTH_POLICIES - Returns a list of tagged policies reporting the authorization policies for the permanent handles.
- TPM_CAP_ACT – Returns a list of TPMS_ACT_DATA, each of which contains the handle for the ACT, the remaining time before it expires, and the ACT attributes.

The *moreData* parameter will have a value of YES if there are more values of the requested type that were not returned.

If no next capability exists, the TPM will return a zero-length list and *moreData* will have a value of NO.

30.3 TPM2_TestParms

30.3.1 General Description

This command is used to check to see if specific combinations of algorithm parameters are supported.

The TPM will unmarshal the provided TPMT_PUBLIC_PARMS. If the parameters unmarshal correctly, then the TPM will return TPM_RC_SUCCESS, indicating that the parameters are valid for the TPM. The TPM will return the appropriate unmarshaling error if a parameter is not valid.

30.3.3 Detailed Actions

[[TestParms]]

31 Non-volatile Storage

31.1 Introduction

The NV commands are used to create, update, read, and delete allocations of space in NV memory. Before an Index may be used, it must be defined (TPM2_NV_DefineSpace()).

An Index may be modified if the proper write authorization is provided or read if the proper read authorization is provided. Different controls are available for reading and writing.

An Index may have an Index-specific *authValue* and *authPolicy*. The *authValue* may be used to authorize reading if TPMA_NV_AUTHREAD is SET and writing if TPMA_NV_AUTHWRITE is SET. The *authPolicy* may be used to authorize reading if TPMA_NV_POLICYREAD is SET and writing if TPMA_NV_POLICYWRITE is SET.

For commands that have both *authHandle* and *nvIndex* parameters, *authHandle* can be an NV Index, Platform Authorization, or Owner Authorization. If *authHandle* is an NV Index, it must be the same as *nvIndex* (TPM_RC_NV_AUTHORIZATION).

TPMA_NV_PPREAD and TPMA_NV_PPWRITE indicate if reading or writing of the NV Index may be authorized by *platformAuth* or *platformPolicy*.

TPMA_NV_OWNERREAD and TPMA_NV_OWNERWRITE indicate if reading or writing of the NV Index may be authorized by *ownerAuth* or *ownerPolicy*.

If an operation on an NV index requires authorization, and the authHandle parameter is the handle of an NV Index, then the nvIndex parameter must have the same value or the TPM will return TPM_RC_NV_AUTHORIZATION.

NOTE 1 This check ensures that the authorization that was provided is associated with the NV Index being authorized.

For creating an Index, Owner Authorization may not be used if *shEnable* is CLEAR and Platform Authorization may not be used if *phEnableNV* is CLEAR.

If an Index was defined using Platform Authorization, then that Index is not accessible when *phEnableNV* is CLEAR. If an Index was defined using Owner Authorization, then that Index is not accessible when *shEnable* is CLEAR.

For read access control, any combination of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD is allowed as long as at least one is SET.

For write access control, any combination of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE is allowed as long as at least one is SET.

If an Index has been defined and not written, then any operation on the NV Index that requires read authorization will fail (TPM_RC_NV_INITIALIZED). This check may be made before or after other authorization checks but shall be performed before checking the NV Index *authValue*. An authorization failure due to the NV Index not having been written shall not be logged by the dictionary attack logic.

If TPMA_NV_CLEAR_STCLEAR is SET, then the TPMA_NV_WRITTEN will be CLEAR on each TPM2_Startup(TPM_SU_CLEAR). TPMA_NV_CLEAR_STCLEAR shall not be SET if the *nvIndexType* is TPM_NT_COUNTER.

The code in the “Detailed Actions” clause of each command is written to interface with an implementation-dependent library that allows access to NV memory. The actions assume no specific layout of the structure of the NV data.

Only one NV Index may be directly referenced in a command.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

NOTE 2 This means that, if *authHandle* references an NV Index, then *nvIndex* will have the same value. However, this does not limit the number of changes that may occur as side effects. For example, any number of NV Indexes might be relocated as a result of deleting or adding a NV Index.

 Copyright © TCG 2006-2020

31.2 NV Counters

When an Index has the TPM_NT_COUNTER attribute, it behaves as a monotonic counter and may only be updated using TPM2_NV_Increment().

When an NV counter is created, the TPM shall initialize the 8-octet counter value with a number that is greater than any count value for any NV counter on the TPM since the time of TPM manufacture.

An NV counter may be defined with the TPMA_NV_ORDERLY attribute to indicate that the NV Index is expected to be modified at a high frequency and that the data is only required to persist when the TPM goes through an orderly shutdown process. The TPM may update the counter value in RAM and occasionally update the non-volatile version of the counter. An orderly shutdown is one occasion to update the non-volatile count. If the difference between the volatile and non-volatile version of the counter becomes as large as MAX_ORDERLY_COUNT, this shall be another occasion for updating the non-volatile count.

Before an NV counter can be used, the TPM shall validate that the count is not less than a previously reported value. If the TPMA_NV_ORDERLY attribute is not SET, or if the TPM experienced an orderly shutdown, then the count is assumed to be correct. If the TPMA_NV_ORDERLY attribute is SET, and the TPM shutdown was not orderly, then the TPM shall OR MAX_ORDERLY_COUNT to the contents of the non-volatile counter and set that as the current count.

NOTE 1 Because the TPM would have updated the NV Index if the difference between the count values was equal to MAX_ORDERLY_COUNT + 1, the highest value that could have been in the NV Index is MAX_ORDERLY_COUNT so it is safe to restore that value.

NOTE 2 The TPM may implement the RAM portion of the counter such that the effective value of the NV counter is the sum of both the volatile and non-volatile parts. If so, then the TPM may initialize the RAM version of the counter to MAX_ORDERLY_COUNT and no update of NV is necessary.

NOTE 3 When a new NV counter is created, the TPM may search all the counters to determine which has the highest value. In this search, the TPM would use the sum of the non-volatile and RAM portions of the counter. The RAM portion of the counter shall be properly initialized to reflect shutdown process (orderly or not) of the TPM.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

31.3 TPM2_NV_DefineSpace

31.3.1 General Description

This command defines the attributes of an NV Index and causes the TPM to reserve space to hold the data associated with the NV Index. If a definition already exists at the NV Index, the TPM will return TPM_RC_NV_DEFINED.

The TPM will return TPM_RC_ATTRIBUTES if *nvIndexType* has a reserved value in *publicInfo.*

NOTE 1 It is not required that any of these three attributes be set.

The TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_WRITTEN, TPMA_NV_READLOCKED, or TPMA_NV_WRITELOCKED is SET.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS, TPM_NT_PIN_FAIL, or TPM_NT_PIN_PASS, then *publicInfo→dataSize* shall be set to eight (8) or the TPM shall return TPM_RC_SIZE.

If *nvIndexType* is TPM_NT_EXTEND, then *publicInfo→dataSize* shall match the digest size of the *publicInfo.nameAlg* or the TPM shall return TPM_RC_SIZE.

NOTE 2 TPM_RC_ATTRIBUTES could be returned by a TPM that is based on the reference code of older versions of the specification but the correct response for this error is TPM_RC_SIZE.

If the NV Index is an ordinary Index and *publicInfo→dataSize* is larger than supported by the TPM implementation then the TPM shall return TPM_RC_SIZE.

NOTE 3 The limit for the data size may vary according to the type of the index. For example, if the index has TPMA_NV_ORDERLY SET, then the maximum size of an ordinary NV Index may be less than the size of an ordinary NV Index that has TPMA_NV_ORDERLY CLEAR.

At least one of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

At least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_CLEAR_STCLEAR is SET, then *nvIndexType* shall not be TPM_NT_COUNTER or the TPM shall return TPM_RC_ATTRIBUTES.

If *platformAuth/platformPolicy* is used for authorization, then TPMA_NV_PLATFORMCREATE shall be SET in *publicInfo*. If *ownerAuth/ownerPolicy* is used for authorization, TPMA_NV_PLATFORMCREATE shall be CLEAR in *publicInfo.* If TPMA_NV_PLATFORMCREATE is not set correctly for the authorization, the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_POLICY_DELETE is SET, then the authorization shall be with Platform Authorization or the TPM shall return TPM_RC_ATTRIBUTES.

If *nvIndexType* is TPM_NT_PIN_FAIL, then TPMA_NV_NO_DA shall be SET. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 4 The intent of a PIN Fail index is that its DA protection is on a per-index basis, not based on the global DA protection. This avoids conflict over which type of dictionary attack protection is in use.

If *nvIndexType* is TPM_NT_PIN_FAIL or TPM_NT_PIN_PASS, then at least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_AUTHWRITE shall be CLEAR. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 5 If TPMA_NV_AUTHWRITE was SET for a PIN Pass index, a user knowing the authorization value could decrease pinCount or increase pinLimit, defeating the purpose of a PIN Pass index. The requirement is also enforced for a PIN Fail index for consistency.

If the implementation does not support TPM2_NV_Increment(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_COUNTER.

If the implementation does not support TPM2_NV_SetBits(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_BITS.

If the implementation does not support TPM2_NV_Extend(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_EXTEND.

If the implementation does not support TPM2_NV_UndefineSpaceSpecial(), the TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_POLICY_DELETE is SET.

After the successful completion of this command, the NV Index exists but TPMA_NV_WRITTEN will be CLEAR. Any access of the NV data will return TPM_RC_NV_UNINITIALIZED.

In some implementations, an NV Index with the TPM_NT_COUNTER attribute may require special TPM resources that provide higher endurance than regular NV. For those implementations, if this command fails because of lack of resources, the TPM will return TPM_RC_NV_SPACE.

The value of *auth* is saved in the created structure. The size of *auth* is limited to be no larger than the size of the digest produced by the NV Index's *nameAlg* (TPM_RC_SIZE).

[[NV_DefineSpace]]

31.4 TPM2_NV_UndefineSpace

31.4.1 General Description

This command removes an Index from the TPM.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE attribute SET, the TPM shall return TPM_RC_NV_AUTHORIZATION unless Platform Authorization is provided.

If *nvIndex* references an Index that has its TPMA_NV_POLICY_DELETE attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR may be deleted with Platform Authorization as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

31.4.3 Detailed Actions

[[NV_UndefineSpace]]

31.5 TPM2_NV_UndefineSpaceSpecial

31.5.1 General Description

This command allows removal of a platform-created NV Index that has TPMA_NV_POLICY_DELETE SET.

This command requires that the policy of the NV Index be satisfied before the NV Index may be deleted. Because administrative role is required, the policy must contain a command that sets the policy command code to TPM_CC_NV_UndefineSpaceSpecial. This indicates that the policy that is being used is a policy that is for this command, and not a policy that would approve another use. That is, authority to use an entity does not grant authority to undefine the entity.

Since the index is deleted, the Empty Buffer is used as the authValue when generating the response HMAC.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE or TPMA_NV_POLICY_DELETE attribute CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR may be deleted with TPM2_UndefineSpace()as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

31.7 TPM2_NV_Write

31.7.1 General Description

This command writes a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPWRITE; TPMA_NV_OWNERWRITE; TPMA_NV_AUTHWRITE; and, if TPMA_NV_POLICY_WRITE is SET, the *authPolicy* of the NV Index.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 1 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS or TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

If the TPMA_NV_WRITEALL attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_RANGE if the size of the *data* parameter of the command is not the same as the *data* field of the NV Index.

If all checks succeed, the TPM will merge the *data.size* octets of *data.buffer* value into the *nvIndex→data* starting at *nvIndex→data[offset].* If the NV memory is implemented with a technology that has endurance limitations, the TPM shall check that the merged data is different from the current contents of the NV Index and only perform a write to NV memory if they differ.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 2 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined or the NV Index is cleared.

31.8 TPM2_NV_Increment

31.8.1 General Description

This command is used to increment the value in an NV Index that has the TPM_NT_COUNTER attribute. The data value of the NV Index is incremented by one.

NOTE 1 The NV Index counter is an unsigned value.

If *nvIndexType* is not TPM_NT_COUNTER in the indicated NV Index, the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_WRITELOCKED is SET, the TPM shall return TPM_RC_NV_LOCKED.

If TPMA_NV_WRITTEN is CLEAR, it will be SET.

If TPMA_NV_ORDERLY is SET, and the difference between the volatile and non-volatile versions of this field is greater than MAX_ORDERLY_COUNT, then the non-volatile version of the counter is updated.

NOTE 2 If a TPM implements TPMA_NV_ORDERLY and an Index is defined with TPMA_NV_ORDERLY and TPM_NT_COUNTER both SET, then in the Event of a non-orderly shutdown, the non-volatile value for the counter Index will be advanced by MAX_ORDERLY_COUNT at the next TPM2_Startup().

NOTE 3 An allowed implementation would keep a counter value in NV and a resettable counter in RAM. The reported value of the NV Index would be the sum of the two values. When the RAM count increments past the maximum allowed value (MAX_ORDERLY_COUNT), the non-volatile version of the count is updated with the sum of the values and the RAM count is reset to zero.

[[NV_Increment]]

31.9 TPM2_NV_Extend

31.9.1 General Description

This command extends a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace.

If *nvIndexType* is not TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

Proper write authorizations are required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and the *authPolicy* of the NV Index.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 1 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined, unless the TPMA_NV_CLEAR_STCLEAR attribute is SET and a TPM Reset or TPM Restart occurs.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 2 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

The *data.buffer* parameter may be larger than the defined size of the NV Index.

The Index will be updated by:

$$nvIndex{\rightarrow}data_{new} \coloneqq \mathbf{H}_{nameAkg}(nvIndex{\rightarrow}data_{old} \mid\mid data.buffer) \tag{41}$$

where

$nvIndex{\rightarrow}data_{new}$	the value of the data field in the NV Index after the command returns
$\mathbf{H}_{nameAkg}()$	the hash algorithm indicated in *nvIndex→nameAlg*
$nvIndex{\rightarrow}data_{old}$	the value of the data field in the NV Index before the command is called
$data.buffer$	the data buffer of the command parameter

NOTE 3 If TPMA_NV_WRITTEN is CLEAR, then $nvIndex{\rightarrow}data_{old}$ is a Zero Digest.

31.10 TPM2_NV_SetBits

31.10.1 General Description

This command is used to SET bits in an NV Index that was created as a bit field. Any number of bits from 0 to 64 may be SET. The contents of *bits* are ORed with the current contents of the NV Index.

If TPMA_NV_WRITTEN is not SET, then, for the purposes of this command, the NV Index is considered to contain all zero bits and *data* is ORed with that value.

If TPM_NT_BITS is not SET, then the TPM shall return TPM_RC_ATTRIBUTES.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE TPMA_NV_WRITTEN will be SET even if no bits were SET.

31.10.3 Detailed Actions

[[NV_SetBits]]

31.11 TPM2_NV_WriteLock

31.11.1 General Description

If the TPMA_NV_WRITEDEFINE or TPMA_NV_WRITE_STCLEAR attributes of an NV location are SET, then this command may be used to inhibit further writes of the NV Index.

Proper write authorization is required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and the *authPolicy* of the NV Index.

It is not an error if TPMA_NV_WRITELOCKED for the NV Index is already SET.

If neither TPMA_NV_WRITEDEFINE nor TPMA_NV_WRITE_STCLEAR of the NV Index is SET, then the TPM shall return TPM_RC_ATTRIBUTES.

If the command is properly authorized and TPMA_NV_WRITE_STCLEAR or TPMA_NV_WRITEDEFINE is SET, then the TPM shall SET TPMA_NV_WRITELOCKED for the NV Index. TPMA_NV_WRITELOCKED will be clear on the next TPM2_Startup(TPM_SU_CLEAR) if either TPMA_NV_WRITEDEFINE is CLEAR or TPMA_NV_WRITTEN is CLEAR.

31.12 TPM2_NV_GlobalWriteLock

31.12.1 General Description

The command will SET TPMA_NV_WRITELOCKED for all indexes that have their TPMA_NV_GLOBALLOCK attribute SET.

If an Index has both TPMA_NV_GLOBALLOCK and TPMA_NV_WRITEDEFINE SET, then this command will permanently lock the NV Index for writing unless TPMA_NV_WRITTEN is CLEAR.

NOTE If an Index is defined with TPMA_NV_GLOBALLOCK SET, then the global lock does not apply until the next time this command is executed.

This command requires either platformAuth/platformPolicy or ownerAuth/ownerPolicy.

31.12.3 Detailed Actions

[[NV_GlobalWriteLock]]

31.13 TPM2_NV_Read

31.13.1 General Description

This command reads a value from an area in NV memory previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and the *authPolicy* of the NV Index.

If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

NOTE 1 If authorization sessions are present, they are checked before the read-lock status of the NV Index is checked.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

The *data* parameter in the response may be encrypted using parameter encryption.

31.13.3 Detailed Actions

[[NV_Read]]

31.14 TPM2_NV_ReadLock

31.14.1 General Description

If TPMA_NV_READ_STCLEAR is SET in an Index, then this command may be used to prevent further reads of the NV Index until the next TPM2_Startup (TPM_SU_CLEAR).

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and the *authPolicy* of the NV Index.

NOTE Only an entity that may read an Index is allowed to lock the NV Index for read.

If the command is properly authorized and TPMA_NV_READ_STCLEAR of the NV Index is SET, then the TPM shall SET TPMA_NV_READLOCKED for the NV Index. If TPMA_NV_READ_STCLEAR of the NV Index is CLEAR, then the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_READLOCKED will be CLEAR by the next TPM2_Startup(TPM_SU_CLEAR).

It is not an error to use this command for an Index that is already locked for reading.

An Index that had not been written may be locked for reading.

31.14.3 Detailed Actions

[[NV_ReadLock]]

31.15 TPM2_NV_ChangeAuth

31.15.1 General Description

This command allows the authorization secret for an NV Index to be changed.

If successful, the authorization secret (*authValue*) of the NV Index associated with *nvIndex* is changed.

This command requires that a policy session be used for authorization of *nvIndex* so that the ADMIN role may be asserted and that *commandCode* in the policy session context shall be TPM_CC_NV_ChangeAuth. That is, the policy must contain a specific authorization for changing the authorization value of the referenced entity.

NOTE The reason for this restriction is to ensure that the administrative actions on *nvIndex* require explicit approval while other commands may use policy that is not command-dependent.

The size of the *newAuth* value may be no larger than the size of the digest produced by the *nameAlg* of the NV Index.

Since the NV Index authorization is changed before the response HMAC is calculated, the newAuth value is used when generating the response HMAC key if required. See TPM 2.0 Part 4 ComputeResponseHMAC().

31.16 TPM2_NV_Certify

31.16.1 General Description

The purpose of this command is to certify the contents of an NV Index or portion of an NV Index.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

If proper authorization for reading the NV Index is provided, the portion of the NV Index selected by *size* and *offset* are included in an attestation block and signed using the key indicated by *signHandle*. The attestation includes *size* and *offset* so that the range of the data can be determined. It also includes the NV index Name.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and *size* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index, or if *size* is greater than MAX_NV_BUFFER_SIZE.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

If *size* and *offset* are both zero (0), then *certifyInfo* in the response will contain a TPMS_NV_DIGEST_CERTIFY_INFO, otherwise, it will contain a TPMS_NV_CERTIFY_INFO. The digest in the TPMS_NV_DIGEST_CERTIFY_INFO is created using the digest of the selected signing scheme.

NOTE 3 TPMS_NV_DIGEST_CERTIFY_INFO was added in revision 01.53. It permits TPM2_NV_Certify() to certify NV Index contents that are larger than MAX_NV_BUFFER_SIZE.

32 Attached Components

32.1 Introduction

This section contains commands that allow interaction with an Attached Component (AC).

NOTE The Attached Component feature was added in revision 01.40.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

32.2 TPM2_AC_GetCapability

32.2.1 General Description

The purpose of this command is to obtain information about an Attached Component referenced by an AC handle.

The returned list contains 0 or more values starting at the first tagged value that is equal to or greater than *capability*.

The list returned in *capabilitiesData* contains tagged values that indicate the type of the value.

The TPM will return the lesser of a) the available values, b) the number requested in *count,* or c) the number that will fit within the available response buffer. If additional values with higher *capability* numbers are available, *moreData* will be YES.

NOTE TPM2_AC_GetCapability() was added in revision 01.40.

[[AC_GetCapability]]

32.3 TPM2_AC_Send

32.3.1 General Description

The purpose of this command is to send (copy) a loaded object from the TPM to an Attached Component.

The Object referenced by *sendObject* is required to have *fixedTpm, fixedParent,* and *encryptedDuplication* attributes CLEAR (TPM_RC_ATTRIBUTES). Authorization for *sendObject* is required to be a policy session. The *policySession→commandCode* of the policy session context is required to be TPM_CC_AC_Send (TPM_RC_POLICY_FAIL) to demonstrate that the policy is specific for this command.

Authorization to send to the *ac* is provided by the session associated with *authHandle*.

If an NV Alias is not defined for *ac,* then *authHandle* is required to be either TPM_RH_OWNER or TPM_RH_PLATFORM (TPM_RC_HANDLE).

If an NV Alias is defined for *ac*, then the authorization for *authHandle* is required to be compatible with the write authorization attributes (TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE TPMA_NV_AUTHWRITE, and TPMA_NV_POLICYWRITE) in the NV Alias (TPM_RC_NV_AUTHORIZATION).

NOTE 1 If authorization for *authHandle* is the handle of an NV Index, then it is required to be the NV Alias value for *ac* (TPM_RC_NV_AUTHORIZATION).

If authorization succeeds, the TPM will attempt to send *acDataIn* and relevant portions of *sendObject* to the AC referenced by *ac*.

The TPM will return TPM_RC_SUCCESS if it succeeds in performing all the required authorizations and validations. If problems occur in the process of sending the object from the TPM to the AC, the response code will be TPM_RC_SUCCESS with the AC-dependent error reported in acDataOut.

NOTE 2 TPM2_AC_Send() was added in revision 01.40.

 Copyright © TCG 2006-2020

32.3.3 Detailed Actions

[[AC_Send]]

32.4 TPM2_Policy_AC_SendSelect

32.4.1 General Description

This command allows qualification of the sending (copying) of an Object to an Attached Component (AC). Qualification includes selection of the receiving AC and the method of authentication for the AC, and, in certain circumstances, the Object to be sent may be specified.

If this command is not used in conjunction with TPM2_PolicyAuthorize(), then only the *authHandleName* and *acName* are selected and *includeObject* should be CLEAR.

NOTE 1 In the absence of TPM2_PolicyAuthorize(), a policy session cannot create a *policyDigest* that simultaneously equals the *authPolicy* in an Object and names that Object. This is because the *authPolicy* recorded in an Object is unable to include the Name of the Object as the Name of an Object depends on the Object's *authPolicy*.

NOTE 2 An object's *authPolicy* can incorporate the use of TPM2_PolicyAuthorize(). If the authorizing entity for the TPM2_PolicyAuthorize() command specifies only the *ac* and the *authHandle*, then the resultant *policyDigest* may be applied to the sending of any number of Objects. If the authorizing entity for the TPM2_PolicyAuthorize() specifies also the Name of the Object to be sent, then the resultant *policyDigest* applies only to that specific Object.

If either policySession→cpHash or policySession→nameHash has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, policySession→nameHash will be set to:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectName \mathbin{||} authHandleName \mathbin{||} acName) \quad (42)$$

NOTE 3 A policy cannot specify both *cpHash* and *nameHash* because *policySession→nameHash* and *policySession→cpHash* may share the same memory space.

If the command succeeds, *policySession→policyDigest* will be updated according to the setting of the input parameter *includeObject*. If *includeObject* is SET, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_Policy_AC_SendSelect} \mathbin{||} objectName \mathbin{||} authHandleName \mathbin{||} acName \mathbin{||} includeObject) \quad (43)$$

but if includeObject is CLEAR, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_Policy_AC_SendSelect} \mathbin{||} authHandleName \mathbin{||} acName \mathbin{||} includeObject) \quad (44)$$

NOTE 4 *policySession→nameHash* receives the digest of all Names so that the check performed in TPM2_AC_Send() may be the same regardless of which Names are included in *policySession→policyDigest*. This means that, when TPM2_Policy_AC_SendSelect() is executed, it is only valid for a specific triple of *objectName*, *authHandleName*, and *acName*.

If the command succeeds, *policySession→commandCode* is set to TPM_CC_AC_Send.

NOTE 5 The normal use of TPM2_Policy_AC_SendSelect() is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allows sending to a specific Attached Component. The authorizing entity may want to limit the authorization so that the approval allows only a specific Object to be sent to the Attached Component. In that case, the authorizing entity would approve the *policyDigest* of *equation* (44).

NOTE 6 TPM2_Policy_AC_SendSelect() was added in revision 01.40.

33 Authenticated Countdown Timer

33.1 Introduction

This section contains commands that allow interaction with an Authenticated Countdown Timer (ACT).

NOTE The Authenticated Countdown Timer was added in revision 01.56.

33.2 TPM2_ACT_SetTimeout

33.2.1 General Description

This command is used to set the time remaining before an Authenticated Countdown Timer (ACT) expires.

This command sets TPMS_ACT_DATA.*timeout* (ACT Timeout) to *startTimeout*. The *startTimeout* value is an integer number of seconds and may be zero. The *startTimeout* parameter may be greater, equal, or less than the current value of ACT Timeout.

When ACT Timeout is non-zero, it will count down, once per second until it reaches zero, at which time the *signaled* attribute of the TPMA_ACT associated with *actHandle* is SET.

When ACT Timeout is zero and the *signaled* attribute is SET, writing a *startTimeout* of $FF\ FF\ FF\ FF_{16}$ will clear *signaled* and stop the counting.

There are four states for ACT Timeout and *startTimeout*. The *signaled* attribute will be set as follows:

1) If ACT Timeout is zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.

2) If ACT Timeout is non-zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.

3) If ACT Timeout is zero and *startTimeout* is zero, then *signaled* will be unchanged.

4) If ACT Timeout is non-zero and *startTimeout* is zero, then *signaled* will be SET.

NOTE 1 The ACT signals on a transition from non-zero to zero. The transition can occur either due to TPM2_ACT_SetTimeout() or a decrement. The effect of *signaled* is platform dependent.

NOTE 2 It may take up to one second until ACT Timeout will be set and *signaled* will be CLEAR or SET by TPM2_ACT_SetTimeout() or TPM2_Startup(STATE). This allows the counting and signaling to take place synchronously with the hardware clock tick.

NOTE 3 TPM2_ACT_SetTimeout() was added in revision 01.56.

34 Vendor Specific

34.1 Introduction

This section contains commands that are vendor specific but made public in order to prevent proliferation.

This specification does define TPM2_Vendor_TCG_Test() in order to have at least one command that can be used to ensure the proper operation of the command dispatch code when processing a vendor-specific command.

34.2 TPM2_Vendor_TCG_Test

34.2.1 General Description

This is a placeholder to allow testing of the dispatch code.

34.2.2 Command and Response

Table 248 — TPM2_Vendor_TCG_Test Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Vendor_TCG_Test
TPM2B_DATA	inputData	dummy data

Table 249 — TPM2_Vendor_TCG_Test Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	TPM_RC_SUCCESS
TPM2B_DATA	outputData	dummy data

Trusted Platform Module Library
Part 4: Supporting Routines

1 Scope

This part contains C code that describes the algorithms and methods used by the command code in TPM 2.0 Part 3. The code in this document augments TPM 2.0 Part 2 and TPM 2.0 Part 3 to provide a complete description of a TPM, including the supporting framework for the code that performs the command actions.

Any TPM 2.0 Part 4 code may be replaced by code that provides similar results when interfacing to the action code in TPM 2.0 Part 3. The behavior of code in this document that is not included in an annex is *normative*, as observed at the interfaces with TPM 2.0 Part 3 code. Code in an annex is provided for completeness, that is, to allow a full implementation of the specification from the provided code.

The code in parts 3 and 4 is written to define the behavior of a compliant TPM. In some cases (e.g., firmware update), it is not possible to provide a compliant implementation. In those cases, any implementation provided by the vendor that meets the general description of the function provided in TPM 2.0 Part 3 would be compliant.

The code in parts 3 and 4 is not written to meet any particular level of conformance nor does this specification require that a TPM meet any particular level of conformance.

2 Terms and definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

4 Automation

TPM 2.0 Part 2 and 3 are constructed so that they can be processed by an automated parser. For example, TPM 2.0 Part 2 can be processed to generate header file contents such as structures, typedefs, and enums. TPM 2.0 Part 3 can be processed to generate command and response marshaling and unmarshaling code.

The automated processor is not provided by the TCG. It was used to generate the Microsoft Visual Studio TPM simulator files. These files are not specification reference code, but rather design examples.

The automation produces TPM_Types.h, a header representing TPM 2.0 Part 2. It also produces, for each major clause of Part 4, a header of the form _fp.h with the function prototypes.

EXAMPLE The header file for SessionProcess.c is SessionProcess_fp.h.

4.1 Configuration Parser

The TPM configuration is largely defined by TpmProfiles.h. This file may be edited in order to change the algorithms and commands supported by a TPM implementation.

A parser exists to process a Word document that defines the TPM configuration. This parser is used to create TpmProfiles.h.

4.2 Structure Parser

4.2.1 Introduction

The program that processes the tables in TPM 2.0 Part 2 is called "The TPM 2.0 Part 2 Structure Parser."

NOTE A Perl script was used to parse the tables in TPM 2.0 Part 2 to produce the header files and unmarshaling code in for the reference implementation.

The TPM 2.0 Part 2 Structure Parser takes as input the files produced by the TPM 2.0 Part 2 Configuration Parser and the same TPM 2.0 Part 2 specification that was used as input to the TPM 2.0 Part 2 Configuration Parser. The TPM 2.0 Part 2 Structure Parser will generate all of the C structure constant definitions that are required by the TPM interface. Additionally, the parser will generate unmarshaling code for all structures passed to the TPM, and marshaling code for structures passed from the TPM.

The unmarshaling code produced by the parser uses the prototypes defined below. The unmarshaling code will perform validations of the data to ensure that it is compliant with the limitations on the data imposed by the structure definition and use the response code provided in the table if not.

EXAMPLE: The definition for a TPMI_RH_PROVISION indicates that the primitive data type is a TPM_HANDLE and the only allowed values are TPM_RH_OWNER and TPM_RH_PLATFORM. The definition also indicates that the TPM shall indicate TPM_RC_HANDLE if the input value is not none of these values. The unmarshaling code will validate that the input value has one of those allowed values and return TPM_RC_HANDLE if not.

The sections below describe the function prototypes for the marshaling and unmarshaling code that is automatically generated by the TPM 2.0 Part 2 Structure Parser. These prototypes are described here as the unmarshaling and marshaling of various types occurs in places other than when the command is being parsed or the response is being built. The prototypes and the description of the interface are intended to aid in the comprehension of the code that uses these auto-generated routines.

4.2.2 Unmarshaling Code Prototype

4.2.2.1 Simple Types and Structures

The general form for the unmarshaling code for a simple type or a structure is:

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size);
```

Where:

TYPE	name of the data type or structure
***target**	location in the TPM memory into which the data from ****buffer** is placed
****buffer**	location in input buffer containing the most significant octet (MSO) of ***target**
***size**	number of octets remaining in ****buffer**

When the data is successfully unmarshaled, the called routine will return TPM_RC_SUCCESS. Otherwise, it will return a Format-One response code (see TPM 2.0 Part 2).

If the data is successfully unmarshaled, ***buffer** is advanced point to the first octet of the next parameter in the input buffer and **size** is reduced by the number of octets removed from the buffer.

When the data type is a simple type, the parser will generate code that will unmarshal the underlying type and then perform checks on the type as indicated by the type definition.

When the data type is a structure, the parser will generate code that unmarshals each of the structure elements in turn and performs any additional parameter checks as indicated by the data type.

 Copyright © TCG 2006-2020

4.2.2.2 Union Types

When a union is defined, an extra parameter is defined for the unmarshaling code. This parameter is the selector for the type. The unmarshaling code for the union will unmarshal the type indicated by the selector.

The function prototype for a union has the form:

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size, UINT32 selector);
```

where:

TYPE	name of the union type or structure
***target**	location in the TPM memory into which the data from ****buffer** is placed
****buffer**	location in input buffer containing the most significant octet (MSO) of ***target**
***size**	number of octets remaining in ****buffer**
selector	union selector that determines what will be unmarshaled into ***target**

4.2.2.3 Null Types

In some cases, the structure definition allows an optional "null" value. The "null" value allows the use of the same C type for the entity even though it does not always have the same members.

For example, the TPMI_ALG_HASH data type is used in many places. In some cases, TPM_ALG_NULL is permitted and in some cases it is not. If two different data types had to be defined, the interfaces and code would become more complex because of the number of cast operations that would be necessary. Rather than encumber the code, the "null" value is defined and the unmarshaling code is given a flag to indicate if this instance of the type accepts the "null" parameter or not. When the data type has a "null" value, the function prototype is

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size, BOOL flag);
```

The parser detects when the type allows a "null" value and will always include **flag** in any call to unmarshal that type. **flag** TRUE indicates that null is accepted.

4.2.2.4 Arrays

Any data type may be included in an array. The function prototype use to unmarshal an array for a **TYPE** is

```
TPM_RC TYPE_Array_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size,INT32 count);
```

The generated code for an array uses a **count**-limited loop within which it calls the unmarshaling code for **TYPE**.

4.2.3 Marshaling Code Function Prototypes

4.2.3.1 Simple Types and Structures

The general form for the marshaling code for a simple type or a structure is:

```
UINT16 TYPE_Marshal(TYPE *source, BYTE **buffer, INT32 *size);
```

Where:

 Copyright © TCG 2006-2020

TYPE	name of the data type or structure
***source**	location in the TPM memory containing the value that is to be marshaled in to the designated buffer
****buffer**	location in the output buffer where the first octet of the **TYPE** is to be placed
***size**	number of octets remaining in ****buffer**.

If **buffer** is a NULL pointer, then no data is marshaled, but the routine will compute and return the size of the memory required to marshal the indicated type. ***size** is not changed.

If **buffer** is not a NULL pointer, data is marshaled, ***buffer** is advanced to point to the first octet of the next location in the output buffer, and the called routine will return the number of octets marshaled into ****buffer**. This occurs even if **size** is a NULL pointer. If **size** is a not NULL pointer ***size** is reduced by the number of octets placed in the buffer.

When the data type is a simple type, the parser will generate code that will marshal the underlying type. The presumption is that the TPM internal structures are consistent and correct so the marshaling code does not validate that the data placed in the buffer has a permissible value. The presumption is also that the **size** is sufficient for the source being marshaled.

When the data type is a structure, the parser will generate code that marshals each of the structure elements in turn.

4.2.3.2 Union Types

An extra parameter is defined for the marshaling function of a union. This parameter is the selector for the type. The marshaling code for the union will marshal the type indicated by the selector.

The function prototype for a union has the form:

```
UINT16 TYPE_Marshal(TYPE *source, BYTE **buffer, INT32 *size, UINT32 selector);
```

The parameters have a similar meaning as those in 4.2.2.2 but the data movement is from **source** to **buffer**.

4.2.3.3 Arrays

Any type may be included in an array. The function prototype use to unmarshal an array is:

```
UINT16 TYPE_Array_Marshal(TYPE *source, BYTE **buffer, INT32 *size, INT32 count);
```

4.2.3.4 The generated code for an array uses a count-limited loop within which it calls the marshaling code for TYPE.Table-driven Marshaling

The most recent versions of the TPM code includes the option to use table-driven marshaling rather that the procedural marshaling described in previous clauses in 4.2.2. The structure and processing of this code is complex and is provided in the code.

4.3 Part 3 Parsing

The Command / Response tables in Part 3 of this specification are processed by scripts to produce the command-specific data structures used by functions in this TPM 2.0 Part 4. They are:

- **CommandAttributeData.h** -- This file contains the command attributes reported by TPM2_GetCapability.

 Copyright © TCG 2006-2020

- **CommandAttributes.h** – This file contains the definition of command attributes that are extracted by the parsing code. The file mainly exists to ensure that the parsing code and the function code are using the same attributes.
- **CommandDispatchData.h** – This file contains the data definitions for the table driven version of the command dispatcher.

Part 3 parsing also produces special function prototype files as described in 4.4.

4.4 Function Prototypes

For functions that have entry definitions not defined by Part 3 tables. a script is used to extracts function prototypes from the code. For each .c file that is not in Part 3, a file with the same name is created with a suffix of _fp.h. For example, the function prototypes for Create.c will be placed in a file called Create_fp.h. The _fp.h is added because some files have two types of associated headers: the one containing the function prototypes for the file and another containing definitions that are specific to that file.

In some cases, a function will be replaced by a macro. The macro is defined in the .c file and extracted by the function prototype processor. A special comment tag ("//%") is used to indicate that the line is to be included in the function prototype file. If the "//%" tag occurs at the start of the line, it is deleted. If it occurs later in the line, it is preserved. Removing the "//%/ at the start of the line allows the macro to be placed in the .c file with the tag as a prefix, and then show up in the _fp.h file as the actual macro. This allows the code that includes that function prototype code to use the appropriate macro.

For files that that contain the command actions, a special _fp.h file is created from the tables in Part 3. These files contain:

- the definition of the input and output structure of the function;
- definition of command-specific return code modifiers (parameter identifiers); and
- the function prototype for the command action function.

Create_fp.h (shown below) is prototypical of the command _fp.h files.

```
1   #if CC_Create // Command must be enabled
2   #ifndef _Create_FP_H_
3   #define _Create_FP_H_
```

Input structure definition

```
4   typedef struct {
5       TPMI_DH_OBJECT              parentHandle;
6       TPM2B_SENSITIVE_CREATE      inSensitive;
7       TPM2B_PUBLIC                inPublic;
8       TPM2B_DATA                  outsideInfo;
9       TPML_PCR_SELECTION          creationPCR;
10  } Create_In;
```

Output structure definition

```
11  typedef struct {
12      TPM2B_PRIVATE               outPrivate;
13      TPM2B_PUBLIC                outPublic;
14      TPM2B_CREATION_DATA         creationData;
15      TPM2B_DIGEST                creationHash;
16      TPMT_TK_CREATION            creationTicket;
17  } Create_Out;
```

Response code modifiers

```
18  #define RC_Create_parentHandle   (TPM_RC_H + TPM_RC_1)
```

```
19  #define RC_Create_inSensitive    (TPM_RC_P + TPM_RC_1)
20  #define RC_Create_inPublic       (TPM_RC_P + TPM_RC_2)
21  #define RC_Create_outsideInfo    (TPM_RC_P + TPM_RC_3)
22  #define RC_Create_creationPCR    (TPM_RC_P + TPM_RC_4)
```

Function prototype

```
23  TPM_RC
24  TPM2_Create(
25      Create_In                   *in,
26      Create_Out                  *out
27  );
28  #endif  // _Create_FP_H_
29  #endif  // CC_Create
```

4.5 Portability

Where reasonable, the code is written to be portable. There are a few known cases where the code is not portable. Specifically, the handling of bit fields will not always be portable. The bit fields are marshaled and unmarshaled as a simple element of the underlying type. For example, a TPMA_SESSION is defined as a bit field in an octet (BYTE). When sent on the interface a TPMA_SESSION will occupy one octet. When unmarshaled, it is unmarshaled as a UINT8. The ramifications of this are that a TPMA_SESSION will occupy the 0th octet of the structure in which it is placed regardless of the size of the structure.

Many compilers will pad a bit field to some "natural" size for the processor, often 4 octets, meaning that `sizeof(TPMA_SESSION)` would return 4 rather than 1 (the canonical size of a TPMA_SESSION).

For a little endian machine, padding of bit fields should have little consequence since the 0th octet always contains the 0th bit of the structure no matter how large the structure. However, for a big endian machine, the 0th bit will be in the highest numbered octet. When unmarshaling a TPMA_SESSION, the current unmarshaling code will place the input octet at the 0th octet of the TPMA_SESSION. Since the 0th octet is most significant octet, this has the effect of shifting all the session attribute bits left by 24 places.

As a consequence, someone implementing on a big endian machine should do one of two things:

a) allocate all structures as packed to a byte boundary (this may not be possible if the processor does not handle unaligned accesses); or

b) modify the code that manipulates bit fields that are not defined as being the alignment size of the system.

For many RISC processors, option #2 would be the only choice. This is may not be a terribly daunting task since only two attribute structures are not 32-bits (TPMA_SESSION and TPMA_LOCALITY).

5 Header Files

5.1 Introduction

The files in this section are used to define values that are used in multiple parts of the specification and are not confined to a single module.

5.2 BaseTypes.h

```
1   #ifndef _BASE_TYPES_H_
2   #define _BASE_TYPES_H_
```

NULL definition

```
3   #ifndef NULL
4   #define NULL                (0)
5   #endif
6   typedef uint8_t             UINT8;
7   typedef uint8_t             BYTE;
8   typedef int8_t              INT8;
9   typedef int                 BOOL;
10  typedef uint16_t            UINT16;
11  typedef int16_t             INT16;
12  typedef uint32_t            UINT32;
13  typedef int32_t             INT32;
14  typedef uint64_t            UINT64;
15  typedef int64_t             INT64;
16  #endif // _BASE_TYPES_H_
```

5.3 Capabilities.h

This file contains defines for the number of capability values that will fit into the largest data buffer.

These defines are used in various function in the "support" and the "subsystem" code groups. A module that supports a type that is returned by a capability will have a function that returns the capabilities of the type.

EXAMPLE PCR.c contains PCRCapGetHandles() and PCRCapGetProperties().

```
1  #ifndef     _CAPABILITIES_H
2  #define     _CAPABILITIES_H
3  #define     MAX_CAP_DATA          (MAX_CAP_BUFFER - sizeof(TPM_CAP)-sizeof(UINT32))
4  #define     MAX_CAP_ALGS          (MAX_CAP_DATA / sizeof(TPMS_ALG_PROPERTY))
5  #define     MAX_CAP_HANDLES       (MAX_CAP_DATA / sizeof(TPM_HANDLE))
6  #define     MAX_CAP_CC            (MAX_CAP_DATA / sizeof(TPM_CC))
7  #define     MAX_TPM_PROPERTIES    (MAX_CAP_DATA / sizeof(TPMS_TAGGED_PROPERTY))
8  #define     MAX_PCR_PROPERTIES    (MAX_CAP_DATA / sizeof(TPMS_TAGGED_PCR_SELECT))
9  #define     MAX_ECC_CURVES        (MAX_CAP_DATA / sizeof(TPM_ECC_CURVE))
10 #define     MAX_TAGGED_POLICIES   (MAX_CAP_DATA / sizeof(TPMS_TAGGED_POLICY))
11 #define     MAX_ACT_DATA          (MAX_CAP_DATA / sizeof(TPMS_ACT_DATA))
12 #define     MAX_AC_CAPABILITIES   (MAX_CAP_DATA / sizeof(TPMS_AC_OUTPUT))
13 #endif
```

 Copyright © TCG 2006-2020

5.4 CommandAttributeData.h

This file should only be included by CommandCodeAttibutes.c

```
1  #ifdef _COMMAND_CODE_ATTRIBUTES_
2  #include "CommandAttributes.h"
3  #if COMPRESSED_LISTS
4  #   define      PAD_LIST    0
5  #else
6  #   define      PAD_LIST    1
7  #endif
```

This is the command code attribute array for GetCapability(). Both this array and *s_commandAttributes* provides command code attributes, but tuned for different purpose

```
8  const TPMA_CC    s_ccAttr [] = {

5.5 CommandAttributes.h

The attributes defined in this file are produced by the parser that creates the structure definitions from Part 3. The attributes are defined in that parser and should track the attributes being tested in CommandCodeAttributes.c. Generally, when an attribute is added to this list, new code will be needed in CommandCodeAttributes.c to test it.

```
 1  #ifndef COMMAND_ATTRIBUTES_H
 2  #define COMMAND_ATTRIBUTES_H
 3  typedef UINT16              COMMAND_ATTRIBUTES;
 4  #define NOT_IMPLEMENTED     (COMMAND_ATTRIBUTES)(0)
 5  #define ENCRYPT_2           ((COMMAND_ATTRIBUTES)1 << 0)
 6  #define ENCRYPT_4           ((COMMAND_ATTRIBUTES)1 << 1)
 7  #define DECRYPT_2           ((COMMAND_ATTRIBUTES)1 << 2)
 8  #define DECRYPT_4           ((COMMAND_ATTRIBUTES)1 << 3)
 9  #define HANDLE_1_USER       ((COMMAND_ATTRIBUTES)1 << 4)
10  #define HANDLE_1_ADMIN      ((COMMAND_ATTRIBUTES)1 << 5)
11  #define HANDLE_1_DUP        ((COMMAND_ATTRIBUTES)1 << 6)
12  #define HANDLE_2_USER       ((COMMAND_ATTRIBUTES)1 << 7)
13  #define PP_COMMAND          ((COMMAND_ATTRIBUTES)1 << 8)
14  #define IS_IMPLEMENTED      ((COMMAND_ATTRIBUTES)1 << 9)
15  #define NO_SESSIONS         ((COMMAND_ATTRIBUTES)1 << 10)
16  #define NV_COMMAND          ((COMMAND_ATTRIBUTES)1 << 11)
17  #define PP_REQUIRED         ((COMMAND_ATTRIBUTES)1 << 12)
18  #define R_HANDLE            ((COMMAND_ATTRIBUTES)1 << 13)
19  #define ALLOW_TRIAL         ((COMMAND_ATTRIBUTES)1 << 14)
20  #endif // COMMAND_ATTRIBUTES_H
```

5.6 CommandDispatchData.h

This file should only be included by CommandCodeAttibutes.c

```
1   #ifdef _COMMAND_TABLE_DISPATCH_
```

Define the stop value

```
2   #define END_OF_LIST     0xff
3   #define ADD_FLAG        0x80
```

These macros provide some variability in how the data is encoded. They also make the lines a little shorter. ;-)

```
4   #if TABLE_DRIVEN_MARSHAL
5   #   define UNMARSHAL_DISPATCH(name)    (marshalIndex_t)name##_MARSHAL_REF
6   #   define MARSHAL_DISPATCH(name)      (marshalIndex_t)name##_MARSHAL_REF
7   #   define _UNMARSHAL_T_    marshalIndex_t
8   #   define _MARSHAL_T_      marshalIndex_t
9   #
10  #else
11  #   define UNMARSHAL_DISPATCH(name)    (UNMARSHAL_t)name##_Unmarshal
12  #   define MARSHAL_DISPATCH(name)      (MARSHAL_t)name##_Marshal
13  #   define _UNMARSHAL_T_    UNMARSHAL_t
14  #   define _MARSHAL_T_      MARSHAL_t
15  #endif
```

The UnmarshalArray() contains the dispatch functions for the unmarshaling code. The defines in this array are used to make it easier to cross reference the unmarshaling values in the types array of each command

```
16  const _UNMARSHAL_T_ UnmarshalArray[] = {
17  #define TPMI_DH_CONTEXT_H_UNMARSHAL             0
18              UNMARSHAL_DISPATCH(TPMI_DH_CONTEXT),
19  #define TPMI_RH_AC_H_UNMARSHAL                  (TPMI_DH_CONTEXT_H_UNMARSHAL + 1)
20              UNMARSHAL_DISPATCH(TPMI_RH_AC),
21  #define TPMI_RH_ACT_H_UNMARSHAL                 (TPMI_RH_AC_H_UNMARSHAL + 1)
22              UNMARSHAL_DISPATCH(TPMI_RH_ACT),
23  #define TPMI_RH_CLEAR_H_UNMARSHAL               (TPMI_RH_ACT_H_UNMARSHAL + 1)
24              UNMARSHAL_DISPATCH(TPMI_RH_CLEAR),
25  #define TPMI_RH_HIERARCHY_AUTH_H_UNMARSHAL      (TPMI_RH_CLEAR_H_UNMARSHAL + 1)
26              UNMARSHAL_DISPATCH(TPMI_RH_HIERARCHY_AUTH),
27  #define TPMI_RH_HIERARCHY_POLICY_H_UNMARSHAL    \

355 #include "Policy_AC_SendSelect_fp.h"
356 #endif
```

Authenticated Countdown Timer

```
357 #ifdef TPM_CC_ACT_SetTimeout
358 #include "ACT_SetTimeout_fp.h"
359 #endif
```

Vendor Specific

```
360 #ifdef TPM_CC_Vendor_TCG_Test
361 #include "Vendor_TCG_Test_fp.h"
362 #endif
363 #endif
```

5.8 CompilerDependencies.h

This file contains the build switches. This contains switches for multiple versions of the crypto-library so some may not apply to your environment.

```
1  #ifndef _COMPILER_DEPENDENCIES_H_
2  #define _COMPILER_DEPENDENCIES_H_
3  #ifdef GCC
4  #   undef _MSC_VER
5  #   undef WIN32
6  #endif
7  #ifdef _MSC_VER
```

These definitions are for the Microsoft compiler Endian conversion for aligned structures

```
8  #   define REVERSE_ENDIAN_16(_Number) _byteswap_ushort(_Number)
9  #   define REVERSE_ENDIAN_32(_Number) _byteswap_ulong(_Number)
10 #   define REVERSE_ENDIAN_64(_Number) _byteswap_uint64(_Number)
```

Avoid compiler warning for in line of stdio (or not)

```
11 //#define _NO_CRT_STDIO_INLINE
```

This macro is used to handle LIB_EXPORT of function and variable names in lieu of a .def file. Visual Studio requires that functions be explicitly exported and imported.

```
12 #   define LIB_EXPORT __declspec(dllexport) // VS compatible version
13 #   define LIB_IMPORT __declspec(dllimport)
```

This is defined to indicate a function that does not return. Microsoft compilers do not support the _Noretrun function parameter.

```
14 #   define NORETURN  __declspec(noreturn)
15 #   if _MSC_VER >= 1400     // SAL processing when needed
16 #       include <sal.h>
17 #   endif
18 #   ifdef _WIN64
19 #       define _INTPTR 2
20 #    else
21 #       define _INTPTR 1
22 #    endif
23 #define NOT_REFERENCED(x)    (x)
```

Lower the compiler error warning for system include files. They tend not to be that clean and there is no reason to sort through all the spurious errors that they generate when the normal error level is set to /Wall

```
24 #   define _REDUCE_WARNING_LEVEL_(n)                    \
25 __pragma(warning(push, n))
```

Restore the compiler warning level

```
26 #   define _NORMAL_WARNING_LEVEL_                       \
27 __pragma(warning(pop))
28 #   include <stdint.h>
29 #endif
30 #ifndef _MSC_VER
31 #ifndef WINAPI
32 #   define WINAPI
33 #endif
34 #   define __pragma(x)
35 #   define REVERSE_ENDIAN_16(_Number) __builtin_bswap16(_Number)
```

```
36  #   define REVERSE_ENDIAN_32(_Number) __builtin_bswap32(_Number)
37  #   define REVERSE_ENDIAN_64(_Number) __builtin_bswap64(_Number)
38  #endif
39  #if defined(__GNUC__)
40  #   define NORETURN                     __attribute__((noreturn))
41  #   include <stdint.h>
42  #endif
```

Things that are not defined should be defined as NULL

```
43  #ifndef NORETURN
44  #   define NORETURN
45  #endif
46  #ifndef LIB_EXPORT
47  #   define LIB_EXPORT
48  #endif
49  #ifndef LIB_IMPORT
50  #   define LIB_IMPORT
51  #endif
52  #ifndef _REDUCE_WARNING_LEVEL_
53  #   define _REDUCE_WARNING_LEVEL_(n)
54  #endif
55  #ifndef _NORMAL_WARNING_LEVEL_
56  #   define _NORMAL_WARNING_LEVEL_
57  #endif
58  #ifndef NOT_REFERENCED
59  #   define  NOT_REFERENCED(x)  (x = x)
60  #endif
61  #ifdef _POSIX_
62  typedef int SOCKET;
63  #endif
64  #endif // _COMPILER_DEPENDENCIES_H_
```

5.9 Global.h

5.9.1 Description

This file contains internal global type definitions and data declarations that are need between subsystems. The instantiation of global data is in Global.c. The initialization of global data is in the subsystem that is the primary owner of the data.

The first part of this file has the typedefs for structures and other defines used in many portions of the code. After the typedef section, is a section that defines global values that are only present in RAM. The next three sections define the structures for the NV data areas: persistent, orderly, and state save. Additional sections define the data that is used in specific modules. That data is private to the module but is collected here to simplify the management of the instance data. All the data is instanced in Global.c.

```
1    #if !defined _TPM_H_
2    #error "Should only be instanced in TPM.h"
3    #endif
```

5.9.2 Includes

Definition for a PROOF value

```
39 TPM2B_TYPE(PROOF, PROOF_SIZE);
```

Definition for a Primary Seed value

```
40 TPM2B_TYPE(SEED, PRIMARY_SEED_SIZE);
```

A CLOCK_NONCE is used to tag the time value in the authorization session and in the ticket computation so that the ticket expires when there is a time discontinuity. When the clock stops during normal operation, the nonce is 64-bit value kept in RAM but it is a 32-bit counter when the clock only stops during power events.

```
41 #if CLOCK_STOPS
42 typedef UINT64          CLOCK_NONCE;
43 #else
44 typedef UINT32          CLOCK_NONCE;
45 #endif
```

5.9.3 Loaded Object Structures

5.9.3.1 Description

The structures in this section define the object layout as it exists in TPM memory.

Two types of objects are defined: an ordinary object such as a key, and a sequence object that may be a hash, HMAC, or event.

5.9.3.2 OBJECT_ATTRIBUTES

An OBJECT_ATTRIBUTES structure contains the variable attributes of an object. These properties are not part of the public properties but are used by the TPM in managing the object. An OBJECT_ATTRIBUTES is used in the definition of the OBJECT data type.

```
46 typedef struct
47 {
48     unsigned            publicOnly : 1;     //0) SET if only the public portion of
49                                             //   an object is loaded
50     unsigned            epsHierarchy : 1;   //1) SET if the object belongs to EPS
51                                             //   Hierarchy
52     unsigned            ppsHierarchy : 1;   //2) SET if the object belongs to PPS
53                                             //   Hierarchy
54     unsigned            spsHierarchy : 1;   //3) SET f the object belongs to SPS
55                                             //   Hierarchy
56     unsigned            evict : 1;          //4) SET if the object is a platform or
57                                             //   owner evict object.  Platform-
58                                             //   evict object belongs to PPS
59                                             //   hierarchy, owner-evict object
60                                             //   belongs to SPS or EPS hierarchy.
61                                             //   This bit is also used to mark a
62                                             //   completed sequence object so it
63                                             //   will be flush when the
64                                             //   SequenceComplete command succeeds.
65     unsigned            primary : 1;        //5) SET for a primary object
66     unsigned            temporary : 1;      //6) SET for a temporary object
67     unsigned            stClear : 1;        //7) SET for an stClear object
68     unsigned            hmacSeq : 1;        //8) SET for an HMAC or MAC sequence
69                                             //   object
70     unsigned            hashSeq : 1;        //9) SET for a hash sequence object
71     unsigned            eventSeq : 1;       //10) SET for an event sequence object
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
72      unsigned            ticketSafe : 1;      //11) SET if a ticket is safe to create
73                                               //    for hash sequence object
74      unsigned            firstBlock : 1;      //12) SET if the first block of hash
75                                               //    data has been received.  It
76                                               //    works with ticketSafe bit
77      unsigned            isParent : 1;        //13) SET if the key has the proper
78                                               //    attributes to be a parent key
79  //    unsigned           privateExp : 1;     //14) SET when the private exponent
80  //                                           //    of an RSA key has been validated.
81      unsigned            not_used_14 : 1;
82      unsigned            occupied : 1;        //15) SET when the slot is occupied.
83      unsigned            derivation : 1;      //16) SET when the key is a derivation
84                                               //        parent
85      unsigned            external : 1;        //17) SET when the object is loaded with
86                                               //    TPM2_LoadExternal();
87  } OBJECT_ATTRIBUTES;
88  #if ALG_RSA
```

There is an overload of the sensitive.rsa.t.size field of a TPMT_SENSITIVE when an RSA key is loaded. When the sensitive->sensitive contains an RSA key with all of the CRT values, then the MSB of the size field will be set to indicate that the buffer contains all 5 of the CRT private key values.

```
89  #define     RSA_prime_flag      0x8000
90  #endif
```

5.9.3.3 OBJECT Structure

An OBJECT structure holds the object public, sensitive, and meta-data associated. This structure is implementation dependent. For this implementation, the structure is not optimized for space but rather for clarity of the reference implementation. Other implementations may choose to overlap portions of the structure that are not used simultaneously. These changes would necessitate changes to the source code but those changes would be compatible with the reference implementation.

```
91  typedef struct OBJECT
92  {
93      // The attributes field is required to be first followed by the publicArea.
94      // This allows the overlay of the object structure and a sequence structure
95      OBJECT_ATTRIBUTES   attributes;          // object attributes
96      TPMT_PUBLIC         publicArea;          // public area of an object
97      TPMT_SENSITIVE      sensitive;           // sensitive area of an object
98      TPM2B_NAME          qualifiedName;       // object qualified name
99      TPMI_DH_OBJECT      evictHandle;         // if the object is an evict object,
100                                              // the original handle is kept here.
101                                              // The 'working' handle will be the
102                                              // handle of an object slot.
103     TPM2B_NAME          name;                // Name of the object name. Kept here
104                                              // to avoid repeatedly computing it.
105 } OBJECT;
```

5.9.3.4 HASH_OBJECT Structure

This structure holds a hash sequence object or an event sequence object.

The first four components of this structure are manually set to be the same as the first four components of the object structure. This prevents the object from being inadvertently misused as sequence objects occupy the same memory as a regular object. A debug check is present to make sure that the offsets are what they are supposed to be.

NOTE: In a future version, this will probably be renamed as SEQUENCE_OBJECT

```
106 typedef struct HASH_OBJECT
```

 Copyright © TCG 2006-2020

```
107 {
108     OBJECT_ATTRIBUTES   attributes;          // The attributes of the HASH object
109     TPMI_ALG_PUBLIC     type;                // algorithm
110     TPMI_ALG_HASH       nameAlg;             // name algorithm
111     TPMA_OBJECT         objectAttributes;    // object attributes
112
113     // The data below is unique to a sequence object
114     TPM2B_AUTH          auth;                // authorization for use of sequence
115     union
116     {
117         HASH_STATE      hashState[HASH_COUNT];
118         HMAC_STATE      hmacState;
119     }                   state;
120 } HASH_OBJECT;
121 typedef BYTE  HASH_OBJECT_BUFFER[sizeof(HASH_OBJECT)];
```

5.9.3.5 ANY_OBJECT

This is the union for holding either a sequence object or a regular object. for ContextSave() and ContextLoad()

```
122 typedef union ANY_OBJECT
123 {
124     OBJECT              entity;
125     HASH_OBJECT         hash;
126 } ANY_OBJECT;
127 typedef BYTE    ANY_OBJECT_BUFFER[sizeof(ANY_OBJECT)];
```

5.9.4 AUTH_DUP Types

These values are used in the authorization processing.

```
128 typedef UINT32          AUTH_ROLE;
129 #define AUTH_NONE       ((AUTH_ROLE)(0))
130 #define AUTH_USER       ((AUTH_ROLE)(1))
131 #define AUTH_ADMIN      ((AUTH_ROLE)(2))
132 #define AUTH_DUP        ((AUTH_ROLE)(3))
```

5.9.5 Active Session Context

5.9.5.1 Description

The structures in this section define the internal structure of a session context.

5.9.5.2 SESSION_ATTRIBUTES

The attributes in the SESSION_ATTRIBUTES structure track the various properties of the session. It maintains most of the tracking state information for the policy session. It is used within the SESSION structure.

```
133 typedef struct SESSION_ATTRIBUTES
134 {
135     unsigned    isPolicy : 1;           //1) SET if the session may only be used
136                                         //   for policy
137     unsigned    isAudit : 1;            //2) SET if the session is used for audit
138     unsigned    isBound : 1;            //3) SET if the session is bound to with an
139                                         //   entity. This attribute will be CLEAR
140                                         //   if either isPolicy or isAudit is SET.
141     unsigned    isCpHashDefined : 1;    //3) SET if the cpHash has been defined
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
142                                                   //   This attribute is not SET unless
143                                                   //   'isPolicy' is SET.
144     unsigned     isAuthValueNeeded : 1;           //5) SET if the authValue is required for
145                                                   //   computing the session HMAC. This
146                                                   //   attribute is not SET unless 'isPolicy'
147                                                   //   is SET.
148     unsigned     isPasswordNeeded : 1;            //6) SET if a password authValue is required
149                                                   //   for authorization This attribute is not
150                                                   //   SET unless 'isPolicy' is SET.
151     unsigned     isPPRequired : 1;                //7) SET if physical presence is required to
152                                                   //   be asserted when the authorization is
153                                                   //   checked. This attribute is not SET
154                                                   //   unless 'isPolicy' is SET.
155     unsigned     isTrialPolicy : 1;               //8) SET if the policy session is created
156                                                   //   for trial of the policy's policyHash
157                                                   //   generation. This attribute is not SET
158                                                   //   unless 'isPolicy' is SET.
159     unsigned     isDaBound : 1;                   //9) SET if the bind entity had noDA CLEAR.
160                                                   //   If this is SET, then an authorization
161                                                   //   failure using this session will count
162                                                   //   against lockout even if the object
163                                                   //   being authorized is exempt from DA.
164     unsigned     isLockoutBound : 1;              //10) SET if the session is bound to
165                                                   //    lockoutAuth.

167                                                   //    authValue of an object is to be
168                                                   //    included in the computation of the
169                                                   //    HMAC key for the command and response
170                                                   //    computations. (was 'requestWasBound')
171     unsigned     checkNvWritten : 1;              //12) SET if the TPMA_NV_WRITTEN attribute
172                                                   //    needs to be checked when the policy is
173                                                   //    used for authorization for NV access.
174                                                   //    If this is SET for any other type, the
175                                                   //    policy will fail.
176     unsigned     nvWrittenState : 1;              //13) SET if TPMA_NV_WRITTEN is required to
177                                                   //    be SET. Used when 'checkNvWritten' is
178                                                   //    SET
179     unsigned     isTemplateSet : 1;               //14) SET if the templateHash needs to be
180                                                   //    checked for Create, CreatePrimary, or
181                                                   //    CreateLoaded.
182 } SESSION_ATTRIBUTES;
```

5.9.5.3 SESSION Structure

The SESSION structure contains all the context of a session except for the associated *contextID*.

NOTE: The *contextID* of a session is only relevant when the session context is stored off the TPM.

```
183 typedef struct SESSION
184 {
185     SESSION_ATTRIBUTES   attributes;          // session attributes
186     UINT32               pcrCounter;          // PCR counter value when PCR is
187                                               // included (policy session)
188                                               // If no PCR is included, this
189                                               // value is 0.
190     UINT64               startTime;           // The value in g_time when the session
191                                               // was started (policy session)
192     UINT64               timeout;             // The timeout relative to g_time
193                                               // There is no timeout if this value
194                                               // is 0.
195     CLOCK_NONCE          epoch;               // The g_clockEpoch value when the
196                                               // session was started. If g_clockEpoch
197                                               // does not match this value when the
198                                               // timeout is used, then
```

```
199                                                // then the command will fail.
200     TPM_CC              commandCode;           // command code (policy session)
201     TPM_ALG_ID          authHashAlg;           // session hash algorithm

205                                                // this session
206     TPM2B_NONCE         nonceTPM;              // last TPM-generated nonce for
207                                                // generating HMAC and encryption keys
208    union
209     {
210         TPM2B_NAME      boundEntity;           // value used to track the entity to
211                                                // which the session is bound
212
213         TPM2B_DIGEST    cpHash;                // the required cpHash value for the
214                                                // command being authorized
215         TPM2B_DIGEST    nameHash;              // the required nameHash
216         TPM2B_DIGEST    templateHash;          // the required template for creation
217     } u1;
218
219     union
220     {
221         TPM2B_DIGEST    auditDigest;           // audit session digest
222         TPM2B_DIGEST    policyDigest;          // policyHash
223     } u2;                                      // audit log and policyHash may
224                                                // share space to save memory
225 } SESSION;
226 #define     EXPIRES_ON_RESET    INT32_MIN
227 #define     TIMEOUT_ON_RESET    UINT64_MAX
228 #define     EXPIRES_ON_RESTART  (INT32_MIN + 1)
229 #define     TIMEOUT_ON_RESTART  (UINT64_MAX - 1)
230 typedef BYTE        SESSION_BUF[sizeof(SESSION)];
```

5.9.6 PCR

5.9.6.1 PCR_SAVE Structure

The PCR_SAVE structure type contains the PCR data that are saved across power cycles. Only the static PCR are required to be saved across power cycles. The DRTM and resettable PCR are not saved. The number of static and resettable PCR is determined by the platform-specific specification to which the TPM is built.

```
231 typedef struct PCR_SAVE
232 {
233 #if     ALG_SHA1
234     BYTE                sha1[NUM_STATIC_PCR][SHA1_DIGEST_SIZE];
235 #endif
236 #if     ALG_SHA256
237     BYTE                sha256[NUM_STATIC_PCR][SHA256_DIGEST_SIZE];
238 #endif
239 #if     ALG_SHA384
240     BYTE                sha384[NUM_STATIC_PCR][SHA384_DIGEST_SIZE];
241 #endif
242 #if     ALG_SHA512
243     BYTE                sha512[NUM_STATIC_PCR][SHA512_DIGEST_SIZE];
244 #endif
245 #if     ALG_SM3_256
246     BYTE                sm3_256[NUM_STATIC_PCR][SM3_256_DIGEST_SIZE];
247 #endif
248
249     // This counter increments whenever the PCR are updated.
250     // NOTE: A platform-specific specification may designate
251     //       certain PCR changes as not causing this counter
```

 Copyright © TCG 2006-2020

```
252     //        to increment.
253     UINT32                  pcrCounter;
254 } PCR_SAVE;
```

5.9.6.2 PCR_POLICY

```
255 #if defined NUM_POLICY_PCR_GROUP && NUM_POLICY_PCR_GROUP > 0
```

This structure holds the PCR policies, one for each group of PCR controlled by policy.

```
256 typedef struct PCR_POLICY
257 {
258     TPMI_ALG_HASH       hashAlg[NUM_POLICY_PCR_GROUP];
259     TPM2B_DIGEST        a;
260     TPM2B_DIGEST        policy[NUM_POLICY_PCR_GROUP];
261 } PCR_POLICY;
262 #endif
```

5.9.6.3 PCR_AUTHVALUE

This structure holds the PCR policies, one for each group of PCR controlled by policy.

```
263 typedef struct PCR_AUTH_VALUE
264 {
265     TPM2B_DIGEST        auth[NUM_AUTHVALUE_PCR_GROUP];
266 } PCR_AUTHVALUE;
```

5.9.7 STARTUP_TYPE

This enumeration is the possible startup types. The type is determined by the combination of TPM2_ShutDown() and TPM2_Startup().

```
267 typedef enum
268 {
269     SU_RESET,
270     SU_RESTART,
271     SU_RESUME
272 } STARTUP_TYPE;
```

5.9.8 NV

5.9.8.1 NV_INDEX

The NV_INDEX structure defines the internal format for an NV index. The *indexData* size varies according to the type of the index. In this implementation, all of the index is manipulated as a unit.

```
273 typedef struct NV_INDEX
274 {
275     TPMS_NV_PUBLIC      publicArea;
276     TPM2B_AUTH          authValue;
277 } NV_INDEX;
```

5.9.8.2 NV_REF

An NV_REF is an opaque value returned by the NV subsystem. It is used to reference and NV Index in a relatively efficient way. Rather than having to continually search for an Index, its reference value may be

used. In this implementation, an NV_REF is a byte pointer that points to the copy of the NV memory that is kept in RAM.

```
278 typedef UINT32           NV_REF;
279 typedef BYTE            *NV_RAM_REF;
```

5.9.8.3 NV_PIN

This structure deals with the possible endianess differences between the canonical form of the TPMS_NV_PIN_COUNTER_PARAMETERS structure and the internal value. The structures allow the data in a PIN index to be read as an 8-octet value using NvReadUINT64Data(). That function will byte swap all the values on a little endian system. This will put the bytes with the 4-octet values in the correct order but will swap the *pinLimit* and *pinCount* values. When written, the PIN index is simply handled as a normal index with the octets in canonical order.

```
280 #if BIG_ENDIAN_TPM
281 typedef struct
282 {
283     UINT32      pinCount;
284     UINT32      pinLimit;
285 } PIN_DATA;
286 #else
287 typedef struct
288 {
289     UINT32      pinLimit;
290     UINT32      pinCount;
291 } PIN_DATA;
292 #endif
293 typedef union
294 {
295     UINT64     intVal;
296     PIN_DATA   pin;
297 } NV_PIN;
```

5.9.9 COMMIT_INDEX_MASK

This is the define for the mask value that is used when manipulating the bits in the commit bit array. The commit counter is a 64-bit value and the low order bits are used to index the *commitArray*. This mask value is applied to the commit counter to extract the bit number in the array.

```
298 #if     ALG_ECC
299 #define COMMIT_INDEX_MASK ((UINT16)((sizeof(gr.commitArray)*8)-1))
300 #endif
```

5.9.10 RAM Global Values

5.9.10.1 Description

The values in this section are only extant in RAM or ROM as constant values.

5.9.10.2 Crypto Self-Test Values

```
301 EXTERN ALGORITHM_VECTOR     g_implementedAlgorithms;
302 EXTERN ALGORITHM_VECTOR     g_toTest;
303
304 //*** g_rcIndex[]
305 // This array is used to contain the array of values that are added to a return
306 // code when it is a parameter-, handle-, or session-related error.
```

 Copyright © TCG 2006-2020

```
307 // This is an implementation choice and the same result can be achieved by using
308 // a macro.
309 #define g_rcIndexInitializer {  TPM_RC_1, TPM_RC_2, TPM_RC_3, TPM_RC_4,           \

313 EXTERN const UINT16     g_rcIndex[15] INITIALIZER(g_rcIndexInitializer);
```

5.9.10.3 g_exclusiveAuditSession

This location holds the session handle for the current exclusive audit session. If there is no exclusive audit session, the location is set to TPM_RH_UNASSIGNED.

```
314 EXTERN TPM_HANDLE       g_exclusiveAuditSession;
315
316 //*** g_time
317 // This is the value in which we keep the current command time. This is initialized
318 // at the start of each command. The time is the accumulated time since the last
319 // time that the TPM's timer was last powered up. Clock is the accumulated time
320 // since the last time that the TPM was cleared. g_time is in mS.
321 EXTERN  UINT64          g_time;
322
323 //*** g_timeEpoch
324 // This value contains the current clock Epoch. It changes when there is a clock
325 // discontinuity. It may be necessary to place this in NV should the timer be able
326 // to run across a power down of the TPM but not in all cases (e.g. dead battery).
327 // If the nonce is placed in NV, it should go in gp because it should be changing
328 // slowly.
329 #if CLOCK_STOPS
330 EXTERN CLOCK_NONCE       g_timeEpoch;
331 #else
332 #define g_timeEpoch      gp.timeEpoch
333 #endif
334
335
336 //*** g_phEnable
337 // This is the platform hierarchy control and determines if the platform hierarchy
338 // is available. This value is SET on each TPM2_Startup(). The default value is
339 // SET.
340 EXTERN BOOL             g_phEnable;
341
342 //*** g_pcrReConfig
343 // This value is SET if a TPM2_PCR_Allocate command successfully executed since
344 // the last TPM2_Startup(). If so, then the next shutdown is required to be
345 // Shutdown(CLEAR).
346 EXTERN BOOL             g_pcrReConfig;
347
348 //*** g_DRTMHandle
349 // This location indicates the sequence object handle that holds the DRTM
350 // sequence data. When not used, it is set to TPM_RH_UNASSIGNED. A sequence
351 // DRTM sequence is started on either _TPM_Init or _TPM_Hash_Start.
352 EXTERN TPMI_DH_OBJECT   g_DRTMHandle;
353
354 //*** g_DrtmPreStartup
355 // This value indicates that an H-CRTM occurred after _TPM_Init but before
356 // TPM2_Startup(). The define for PRE_STARTUP_FLAG is used to add the
357 // g_DrtmPreStartup value to gp_orderlyState at shutdown. This hack is to avoid
358 // adding another NV variable.
359 EXTERN  BOOL            g_DrtmPreStartup;
360
361 //*** g_StartupLocality3
362 // This value indicates that a TPM2_Startup() occurred at locality 3. Otherwise, it
```

 Copyright © TCG 2006-2020

```
363 // at locality 0. The define for STARTUP_LOCALITY_3 is to
364 // indicate that the startup was not at locality 0. This hack is to avoid
365 // adding another NV variable.
366 EXTERN  BOOL            g_StartupLocality3;
367
368 //***TPM_SU_NONE
369 // Part 2 defines the two shutdown/startup types that may be used in
370 // TPM2_Shutdown() and TPM2_Starup(). This additional define is
371 // used by the TPM to indicate that no shutdown was received.
372 // NOTE: This is a reserved value.
373 #define SU_NONE_VALUE           (0xFFFF)
374 #define TPM_SU_NONE             (TPM_SU)(SU_NONE_VALUE)
```

5.9.10.4 TPM_SU_DA_USED

As with TPM_SU_NONE, this value is added to allow indication that the shutdown was not orderly and that a DA=protected object was reference during the previous cycle.

```
375 #define SU_DA_USED_VALUE    (SU_NONE_VALUE - 1)
376 #define TPM_SU_DA_USED      (TPM_SU)(SU_DA_USED_VALUE)
```

5.9.10.5 Startup Flags

These flags are included in *gp.orderlyState*. These are hacks and are being used to avoid having to change the layout of gp. The PRE_STARTUP_FLAG indicates that a _TPM_Hash_Start()/_Data/_End sequence was received after _TPM_Init() but before TPM2_StartUp(). STARTUP_LOCALITY_3 indicates that the last TPM2_Startup() was received at locality 3. These flags are only relevant if after a TPM2_Shutdown(STATE).

```
377 #define PRE_STARTUP_FLAG     0x8000
378 #define STARTUP_LOCALITY_3   0x4000
379 #if USE_DA_USED
```

5.9.10.6 g_daUsed

This location indicates if a DA-protected value is accessed during a boot cycle. If none has, then there is no need to increment *failedTries* on the next non-orderly startup. This bit is merged with *gp.orderlyState* when that gp.orderly is set to SU_NONE_VALUE

```
380 EXTERN  BOOL                g_daUsed;
381 #endif
382
383 //*** g_updateNV

```

5.9.11 Global Macro Definitions

The NV_READ_PERSISTENT and NV_WRITE_PERSISTENT macros are used to access members of the PERSISTENT_DATA structure in NV.

```
837 #define NV_READ_PERSISTENT(to, from)                \
838             NvRead(&to, offsetof(PERSISTENT_DATA, from), sizeof(to))
839 #define NV_WRITE_PERSISTENT(to, from)               \
840             NvWrite(offsetof(PERSISTENT_DATA, to), sizeof(gp.to), &from)
841 #define CLEAR_PERSISTENT(item)                      \
842             NvClearPersistent(offsetof(PERSISTENT_DATA, item), sizeof(gp.item))
843 #define NV_SYNC_PERSISTENT(item) NV_WRITE_PERSISTENT(item, gp.item)
```

At the start of command processing, the index of the command is determined. This index value is used to access the various data tables that contain per-command information. There are multiple options for how the per-command tables can be implemented. This is resolved in GetClosestCommandIndex().

```
844  typedef UINT16      COMMAND_INDEX;
845  #define UNIMPLEMENTED_COMMAND_INDEX     ((COMMAND_INDEX)(~0))
846  typedef struct _COMMAND_FLAGS_
847  {
848      unsigned    trialPolicy : 1;    //1) If SET, one of the handles references a
849                                      //   trial policy and authorization may be
850                                      //   skipped. This is only allowed for a policy
851                                      //   command.
852  } COMMAND_FLAGS;
```

This structure is used to avoid having to manage a large number of parameters being passed through various levels of the command input processing.

```
853  typedef struct _COMMAND_

5.10 GpMacros.h

5.10.1 Introduction

This file is a collection of miscellaneous macros.

```
1  #ifndef GP_MACROS_H
2  #define GP_MACROS_H
3  #ifndef NULL
4  #define NULL 0
5  #endif
6  #include "swap.h"
7  #include "VendorString.h"
```

5.10.2 For Self-test

These macros are used in CryptUtil() to invoke the incremental self test.

```
8  #if SELF_TEST
9  #   define     TEST(alg) if(TEST_BIT(alg, g_toTest)) CryptTestAlgorithm(alg, NULL)
```

Use of TPM_ALG_NULL is reserved for RSAEP/RSADP testing. If someone is wanting to test a hash with that value, don't do it.

```
10 #   define     TEST_HASH(alg)                                                    \
11             if(TEST_BIT(alg, g_toTest)                                            \
12                 &&  (alg != ALG_NULL_VALUE))                                      \
13                 CryptTestAlgorithm(alg, NULL)
14 #else
15 #   define TEST(alg)
16 #   define TEST_HASH(alg)
17 #endif // SELF_TEST
```

5.10.3 For Failures

```
18 #if defined _POSIX_
19 #   define FUNCTION_NAME        0
20 #else
21 #   define FUNCTION_NAME        __FUNCTION__
22 #endif
23 #if !FAIL_TRACE
24 #   define FAIL(errorCode) (TpmFail(errorCode))
25 #   define LOG_FAILURE(errorCode) (TpmLogFailure(errorCode))
26 #else
27 #   define FAIL(errorCode)        TpmFail(FUNCTION_NAME, __LINE__, errorCode)
28 #   define LOG_FAILURE(errorCode) TpmLogFailure(FUNCTION_NAME, __LINE__, errorCode)
29 #endif
```

If implementation is using longjmp, then the call to TpmFail() does not return and the compiler will complain about unreachable code that comes after. To allow for not having longjmp, TpmFail() will return and the subsequent code will be executed. This macro accounts for the difference.

```
30 #ifndef NO_LONGJMP
31 #   define FAIL_RETURN(returnCode)
32 #   define TPM_FAIL_RETURN     NORETURN void
33 #else
34 #   define FAIL_RETURN(returnCode) return (returnCode)
35 #   define TPM_FAIL_RETURN     void
36 #endif
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

This macro tests that a condition is TRUE and puts the TPM into failure mode if it is not. If longjmp is being used, then the FAIL(FATAL_ERROR_) macro makes a call from which there is no return. Otherwise, it returns and the function will exit with the appropriate return code.

```
37  #define REQUIRE(condition, errorCode, returnCode)                              \
38      {                                                                          \
39          if(!!(condition))                                                      \
40          {                                                                      \
41              FAIL(FATAL_ERROR_errorCode);                                       \
42              FAIL_RETURN(returnCode);                                           \
43          }                                                                      \
44      }
45  #define PARAMETER_CHECK(condition, returnCode)                                 \
46      REQUIRE((condition), PARAMETER, returnCode)
47  #if (defined EMPTY_ASSERT) && (EMPTY_ASSERT != NO)
48  #   define pAssert(a)   ((void)0)
49  #else
50  #   define pAssert(a) {if(!(a)) FAIL(FATAL_ERROR_PARAMETER);}
51  #endif
```

5.10.4 Derived from Vendor-specific values

Values derived from vendor specific settings in TpmProfile.h

```
52  #define PCR_SELECT_MIN          ((PLATFORM_PCR+7)/8)
53  #define PCR_SELECT_MAX          ((IMPLEMENTATION_PCR+7)/8)
54  #define MAX_ORDERLY_COUNT       ((1 << ORDERLY_BITS) - 1)
55  #define RSA_MAX_PRIME           (MAX_RSA_KEY_BYTES / 2)
56  #define RSA_PRIVATE_SIZE        (RSA_MAX_PRIME * 5)
```

5.10.5 Compile-time Checks

In some cases, the relationship between two values may be dependent on things that change based on various selections like the chosen cryptographic libraries. It is possible that these selections will result in incompatible settings. These are often detectable by the compiler but it isn't always possible to do the check in the preprocessor code. For example, when the check requires use of **sizeof** then the preprocessor can't do the comparison. For these cases, we include a special macro that, depending on the compiler will generate a warning to indicate if the check always passes or always fails because it involves fixed constants. To run these checks, define COMPILER_CHECKS in TpmBuildSwitches.h

```
57  #if COMPILER_CHECKS
58  #   define  cAssert     pAssert
59  #else
60  #   define cAssert(value)
61  #endif
```

This is used commonly in the **Crypt** code as a way to keep listings from getting too long. This is not to save paper but to allow one to see more useful stuff on the screen at any given time.

```
62  #define     ERROR_RETURN(returnCode)                                           \
63      {                                                                          \
64           retVal = returnCode;                                                  \
65           goto Exit;                                                            \
66      }
67  #ifndef MAX
68  #  define MAX(a, b) ((a) > (b) ? (a) : (b))
69  #endif
70  #ifndef MIN
71  #  define MIN(a, b) ((a) < (b) ? (a) : (b))
72  #endif
73  #ifndef IsOdd
```

```
74    #  define IsOdd(a)         (((a) & 1) != 0)
75    #endif
76    #ifndef BITS_TO_BYTES
77    #  define BITS_TO_BYTES(bits)  (((bits) + 7) >> 3)
78    #endif
```

These are defined for use when the size of the vector being checked is known at compile time.

```
79    #define TEST_BIT(bit, vector)    TestBit((bit), (BYTE *)&(vector), sizeof(vector))
80    #define SET_BIT(bit, vector)     SetBit((bit), (BYTE *)&(vector), sizeof(vector))
81    #define CLEAR_BIT(bit, vector) ClearBit((bit), (BYTE *)&(vector), sizeof(vector))
```

The following definitions are used if they have not already been defined. The defaults for these settings are compatible with ISO/IEC 9899:2011 (E)

```
82    #ifndef LIB_EXPORT
83    #   define LIB_EXPORT
84    #   define LIB_IMPORT
85    #endif
86    #ifndef NORETURN
87    #   define NORETURN _Noreturn
88    #endif
89    #ifndef NOT_REFERENCED
90    #   define NOT_REFERENCED(x = x)    ((void) (x))
91    #endif
92    #define STD_RESPONSE_HEADER (sizeof(TPM_ST) + sizeof(UINT32) + sizeof(TPM_RC))
93    #define JOIN(x, y) x##y
94    #define JOIN3(x, y, z) x##y##z
95    #define CONCAT(x, y) JOIN(x, y)
96    #define CONCAT3(x, y, z) JOIN3(x,y,z)
```

If CONTEXT_INTEGRITY_HASH_ALG is defined, then the vendor is using the old style table. Otherwise, pick the **strongest** implemented hash algorithm as the context hash.

```
97    #ifndef CONTEXT_HASH_ALGORITHM
98    #   if defined ALG_SHA512 && ALG_SHA512 == YES
99    #       define CONTEXT_HASH_ALGORITHM    SHA512
100   #   elif defined ALG_SHA384 && ALG_SHA384 == YES
101   #       define CONTEXT_HASH_ALGORITHM    SHA384
102   #   elif defined ALG_SHA256 && ALG_SHA256 == YES
103   #       define CONTEXT_HASH_ALGORITHM    SHA256
104   #   elif defined ALG_SM3_256 && ALG_SM3_256 == YES
105   #       define CONTEXT_HASH_ALGORITHM    SM3_256
106   #   elif defined ALG_SHA1 && ALG_SHA1 == YES
107   #       define CONTEXT_HASH_ALGORITHM  SHA1
108   #   endif
109   #   define CONTEXT_INTEGRITY_HASH_ALG  CONCAT(TPM_ALG_, CONTEXT_HASH_ALGORITHM)
110   #endif
111   #ifndef CONTEXT_INTEGRITY_HASH_SIZE
112   #define CONTEXT_INTEGRITY_HASH_SIZE CONCAT(CONTEXT_HASH_ALGORITHM, _DIGEST_SIZE)
113   #endif
114   #if     ALG_RSA
115   #define     RSA_SECURITY_STRENGTH (MAX_RSA_KEY_BITS >= 15360 ? 256 :               \
116                                      (MAX_RSA_KEY_BITS >=  7680 ? 192 :              \
117                                      (MAX_RSA_KEY_BITS >=  3072 ? 128 :              \
118                                      (MAX_RSA_KEY_BITS >=  2048 ? 112 :              \
119                                      (MAX_RSA_KEY_BITS >=  1024 ?  80 :   0)))))
120   #else
121   #define     RSA_SECURITY_STRENGTH   0
122   #endif // ALG_RSA
123   #if     ALG_ECC
124   #define     ECC_SECURITY_STRENGTH (MAX_ECC_KEY_BITS >= 521 ? 256 :                 \
125                                      (MAX_ECC_KEY_BITS >= 384 ? 192 :                \
126                                      (MAX_ECC_KEY_BITS >= 256 ? 128 : 0)))
```

```
127 #else
128 #define      ECC_SECURITY_STRENGTH    0
129 #endif // ALG_ECC
130 #define      MAX_ASYM_SECURITY_STRENGTH                                              \
131                          MAX(RSA_SECURITY_STRENGTH, ECC_SECURITY_STRENGTH)
132 #define      MAX_HASH_SECURITY_STRENGTH   ((CONTEXT_INTEGRITY_HASH_SIZE * 8) / 2)
```

Unless some algorithm is broken...

```
133 #define      MAX_SYM_SECURITY_STRENGTH    MAX_SYM_KEY_BITS
134 #define MAX_SECURITY_STRENGTH_BITS                                                   \
135                          MAX(MAX_ASYM_SECURITY_STRENGTH,                             \
136                          MAX(MAX_SYM_SECURITY_STRENGTH,                              \
137                              MAX_HASH_SECURITY_STRENGTH))
```

This is the size that was used before the 1.38 errata requiring that P1.14.4 be followed

```
138 #define PROOF_SIZE         CONTEXT_INTEGRITY_HASH_SIZE
```

As required by P1.14.4

```
139 #define COMPLIANT_PROOF_SIZE                                                         \
140             (MAX(CONTEXT_INTEGRITY_HASH_SIZE, (2 * MAX_SYM_KEY_BYTES)))
```

As required by P1.14.3.1

```
141 #define COMPLIANT_PRIMARY_SEED_SIZE                                                  \
142     BITS_TO_BYTES(MAX_SECURITY_STRENGTH_BITS * 2)
```

This is the pre-errata version

```
143 #ifndef PRIMARY_SEED_SIZE
144 #   define PRIMARY_SEED_SIZE     PROOF_SIZE
145 #endif
146 #if USE_SPEC_COMPLIANT_PROOFS
147 #   undef PROOF_SIZE
148 #   define PROOF_SIZE            COMPLIANT_PROOF_SIZE
149 #   undef PRIMARY_SEED_SIZE
150 #   define PRIMARY_SEED_SIZE     COMPLIANT_PRIMARY_SEED_SIZE
151 #endif   // USE_SPEC_COMPLIANT_PROOFS
152 #if !SKIP_PROOF_ERRORS
153 #   if PROOF_SIZE < COMPLIANT_PROOF_SIZE
154 #       error "PROOF_SIZE is not compliant with TPM specification"
155 #   endif
156 #   if PRIMARY_SEED_SIZE < COMPLIANT_PRIMARY_SEED_SIZE
157 #       error Non-compliant PRIMARY_SEED_SIZE
158 #   endif
159 #endif // !SKIP_PROOF_ERRORS
```

If CONTEXT_ENCRYPT_ALG is defined, then the vendor is using the old style table

```
160 #if defined CONTEXT_ENCRYPT_ALG
161 #   undef CONTEXT_ENCRYPT_ALGORITHM
162 #   if  CONTEXT_ENCRYPT_ALG == ALG_AES_VALUE
163 #       define CONTEXT_ENCRYPT_ALGORITHM    AES
164 #   elif CONTEXT_ENCRYPT_ALG == ALG_SM4_VALUE
165 #       define CONTEXT_ENCRYPT_ALGORITHM    SM4
166 #   elif CONTEXT_ENCRYPT_ALG == ALG_CAMELLIA_VALUE
167 #       define CONTEXT_ENCRYPT_ALGORITHM    CAMELLIA
168 #   elif CONTEXT_ENCRYPT_ALG == ALG_TDES_VALUE
169 #   error Are you kidding?
170 #   else
171 #       error Unknown value for CONTEXT_ENCRYPT_ALG
```

 Copyright © TCG 2006-2020

```
172  #   endif // CONTEXT_ENCRYPT_ALG == ALG_AES_VALUE
173  #else
174  #   define CONTEXT_ENCRYPT_ALG                                          \
175              CONCAT3(ALG_, CONTEXT_ENCRYPT_ALGORITHM, _VALUE)
176  #endif  // CONTEXT_ENCRYPT_ALG
177  #define CONTEXT_ENCRYPT_KEY_BITS                                       \
178                  CONCAT(CONTEXT_ENCRYPT_ALGORITHM, _MAX_KEY_SIZE_BITS)
179  #define CONTEXT_ENCRYPT_KEY_BYTES       ((CONTEXT_ENCRYPT_KEY_BITS+7)/8)
```

This is updated to follow the requirement of P2 that the label not be larger than 32 bytes.

```
180  #ifndef LABEL_MAX_BUFFER
181  #define LABEL_MAX_BUFFER MIN(32, MAX(MAX_ECC_KEY_BYTES, MAX_DIGEST_SIZE))
182  #endif
```

This bit is used to indicate that an authorization ticket expires on TPM Reset and TPM Restart. It is added to the timeout value returned by TPM2_PoliySigned() and TPM2_PolicySecret() and used by TPM2_PolicyTicket(). The timeout value is relative to Time (g_time). Time is reset whenever the TPM loses power and cannot be moved forward by the user (as can Clock). *g_time* is a 64-bit value expressing time in ms. Stealing the MSb for a flag means that the TPM needs to be reset at least once every 292,471,208 years rather than once every 584,942,417 years.

```
183  #define EXPIRATION_BIT ((UINT64)1 << 63)
```

Check for consistency of the bit ordering of bit fields

```
184  #if BIG_ENDIAN_TPM && MOST_SIGNIFICANT_BIT_0 && USE_BIT_FIELD_STRUCTURES
185  #   error "Settings not consistent"
186  #endif
```

These macros are used to handle the variation in handling of bit fields. If

```
187  #if USE_BIT_FIELD_STRUCTURES // The default, old version, with bit fields
188  #   define IS_ATTRIBUTE(a, type, b)        ((a.b) != 0)
189  #   define SET_ATTRIBUTE(a, type, b)       (a.b = SET)
190  #   define CLEAR_ATTRIBUTE(a, type, b)     (a.b = CLEAR)
191  #   define GET_ATTRIBUTE(a, type, b)       (a.b)
192  #   define TPMA_ZERO_INITIALIZER()         {0}
193  #else
194  #   define IS_ATTRIBUTE(a, type, b)        ((a & type##_##b) != 0)
195  #   define SET_ATTRIBUTE(a, type, b)       (a |= type##_##b)
196  #   define CLEAR_ATTRIBUTE(a, type, b)     (a &= ~type##_##b)
197  #   define GET_ATTRIBUTE(a, type, b)                                    \
198          (type)((a & type##_##b) >> type##_##b##_SHIFT)
199  #   define TPMA_ZERO_INITIALIZER()         (0)
200  #endif
201  #define VERIFY(_X) if(!(_X)) goto Error
```

These macros determine if the values in this file are referenced or instanced. Global.c defines GLOBAL_C so all the values in this file will be instanced in Global.obj. For all other files that include this file, the values will simply be external references. For constants, there can be an initializer.

```
202  #ifdef GLOBAL_C
203  #define EXTERN
204  #define INITIALIZER(_value_)  = _value_
205  #else
206  #define EXTERN  extern
207  #define INITIALIZER(_value_)
208  #endif
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

This macro will create an OID. All OIDs are in DER form with a first octet of 0x06 indicating an OID fallowed by an octet indicating the number of octets in the rest of the OID. This allows a user of this OID to know how much/little to copy.

```
209     #define MAKE_OID(NAME)                                                              \
210             EXTERN  const BYTE OID##NAME[] INITIALIZER({OID##NAME##_VALUE})
```

This definition is moved from TpmProfile.h because it is not actually vendor- specific. It has to be the same size as the *sequence* parameter of a TPMS_CONTEXT and that is a UINT64. So, this is an invariant value

```
211     #define CONTEXT_COUNTER         UINT64
212     #endif // GP_MACROS_H
```

 Copyright © TCG 2006-2020

5.12 LibSupport.h

This header file is used to select the library code that gets included in the TPM build.

```
1   #ifndef _LIB_SUPPORT_H_
2   #define _LIB_SUPPORT_H_
3   #ifndef RADIX_BITS
4   #   if defined(__x86_64__) || defined(__x86_64)
    \
5           || defined(__amd64__) || defined(__amd64) || defined(_WIN64) ||
    defined(_M_X64) \
6           || defined(_M_ARM64) || defined(__aarch64__)
7   #       define RADIX_BITS                      64
8   #   elif defined(__i386__) || defined(__i386) || defined(i386)
    \
9           || defined(_WIN32) || defined(_M_IX86)
    \
10          || defined(_M_ARM) || defined(__arm__) || defined(__thumb__)
11  #       define RADIX_BITS                      32
12  #   else
13  #       error Unable to determine RADIX_BITS from compiler environment
14  #   endif
15  #endif // RADIX_BITS
```

These macros use the selected libraries to the proper include files.

```
16  #define LIB_QUOTE(_STRING_) #_STRING_
17  #define LIB_INCLUDE2(_LIB_, _TYPE_) LIB_QUOTE(_LIB_/TpmTo##_LIB_##_TYPE_.h)
18  #define LIB_INCLUDE(_LIB_, _TYPE_) LIB_INCLUDE2(_LIB_, _TYPE_)
```

Include the options for hashing and symmetric. Defer the load of the math package Until the bignum parameters are defined.

```
19  #include LIB_INCLUDE(SYM_LIB, Sym)
20  #include LIB_INCLUDE(HASH_LIB, Hash)
21  #undef MIN
22  #undef MAX
23  #endif // _LIB_SUPPORT_H_
```

5.13 MinMax.h

```
1   #ifndef _MIN_MAX_H_
2   #define _MIN_MAX_H_
3   #ifndef MAX
4   #define MAX(a, b) ((a) > (b) ? (a) : (b))
5   #endif
6   #ifndef MIN
7   #define MIN(a, b) ((a) < (b) ? (a) : (b))
8   #endif
9   #endif // _MIN_MAX_H_
```

5.14 NV.h

5.14.1 Index Type Definitions

These definitions allow the same code to be used pre and post 1.21. The main action is to redefine the index type values from the bit values. Use TPM_NT_ORDINARY to indicate if the TPM_NT type is defined

```
1   #ifndef     _NV_H_
2   #define     _NV_H_
3   #ifdef      TPM_NT_ORDINARY
```

If TPM_NT_ORDINARY is defined, then the TPM_NT field is present in a TPMA_NV

```
4   #   define GET_TPM_NT(attributes) GET_ATTRIBUTE(attributes, TPMA_NV, TPM_NT)
5   #else
```

If TPM_NT_ORDINARY is not defined, then need to synthesize it from the attributes

```
6   #   define GetNv_TPM_NV(attributes)                              \
7           (   IS_ATTRIBUTE(attributes, TPMA_NV, COUNTER)           \
8           +   (IS_ATTRIBUTE(attributes, TPMA_NV, BITS) << 1)       \
9           +   (IS_ATTRIBUTE(attributes, TPMA_NV, EXTEND) << 2)     \
10          )
11  #   define TPM_NT_ORDINARY (0)
12  #   define TPM_NT_COUNTER  (1)
13  #   define TPM_NT_BITS     (2)
14  #   define TPM_NT_EXTEND   (4)
15  #endif
```

5.14.2 Attribute Macros

These macros are used to isolate the differences in the way that the index type changed in version 1.21 of the specification

```
16  #   define IsNvOrdinaryIndex(attributes)                         \
17                  (GET_TPM_NT(attributes) == TPM_NT_ORDINARY)
18  #   define  IsNvCounterIndex(attributes)                         \
19                  (GET_TPM_NT(attributes) == TPM_NT_COUNTER)
20  #   define  IsNvBitsIndex(attributes)                            \
21                 (GET_TPM_NT(attributes) == TPM_NT_BITS)
22  #   define  IsNvExtendIndex(attributes)                          \
23                  (GET_TPM_NT(attributes) == TPM_NT_EXTEND)
24  #ifdef TPM_NT_PIN_PASS
25  #   define  IsNvPinPassIndex(attributes)                         \
26                  (GET_TPM_NT(attributes) == TPM_NT_PIN_PASS)
27  #endif
28  #ifdef TPM_NT_PIN_FAIL
29  #   define  IsNvPinFailIndex(attributes)                         \
30                  (GET_TPM_NT(attributes) == TPM_NT_PIN_FAIL)
31  #endif
32  typedef struct {
33      UINT32      size;
34      TPM_HANDLE  handle;
35  } NV_ENTRY_HEADER;
36  #define NV_EVICT_OBJECT_SIZE        \
37       (sizeof(UINT32)   + sizeof(TPM_HANDLE) + sizeof(OBJECT))
38  #define NV_INDEX_COUNTER_SIZE       \
39      (sizeof(UINT32) + sizeof(NV_INDEX) + sizeof(UINT64))
40  #define NV_RAM_INDEX_COUNTER_SIZE   \
41      (sizeof(NV_RAM_HEADER) + sizeof(UINT64))
```

```
42  typedef struct {
43      UINT32          size;
44      TPM_HANDLE      handle;
45      TPMA_NV         attributes;
46  } NV_RAM_HEADER;
```

Defines the end-of-list marker for NV. The list terminator is a UINT32 of zero, followed by the current value of *s_maxCounter* which is a 64-bit value. The structure is defined as an array of 3 UINT32 values so that there is no padding between the UINT32 list end marker and the UINT64 *maxCounter* value.

```
47  typedef UINT32 NV_LIST_TERMINATOR[3];
```

5.14.3 Orderly RAM Values

The following defines are for accessing orderly RAM values. This is the initialize for the RAM reference iterator.

```
48  #define     NV_RAM_REF_INIT         0
```

This is the starting address of the RAM space used for orderly data

```
49  #define     RAM_ORDERLY_START                 \
50                  (&s_indexOrderlyRam[0])
```

This is the offset within NV that is used to save the orderly data on an orderly shutdown.

```
51  #define     NV_ORDERLY_START                  \
52                  (NV_INDEX_RAM_DATA)
```

This is the end of the orderly RAM space. It is actually the first byte after the last byte of orderly RAM data

```
53  #define     RAM_ORDERLY_END                   \
54                  (RAM_ORDERLY_START + sizeof(s_indexOrderlyRam))
```

This is the end of the orderly space in NV memory. As with RAM_ORDERLY_END, it is actually the offset of the first byte after the end of the NV orderly data.

```
55  #define     NV_ORDERLY_END                    \
56                  (NV_ORDERLY_START + sizeof(s_indexOrderlyRam))
```

Macro to check that an orderly RAM address is with range.

```
57  #define ORDERLY_RAM_ADDRESS_OK(start, offset)       \
58          ((start >= RAM_ORDERLY_START) && ((start + offset - 1) < RAM_ORDERLY_END))
59  #define RETURN_IF_NV_IS_NOT_AVAILABLE               \
60  {                                                   \
61      if(g_NvStatus != TPM_RC_SUCCESS)                \
62          return g_NvStatus;                          \
63  }
```

Routinely have to clear the orderly flag and fail if the NV is not available so that it can be cleared.

```
64  #define RETURN_IF_ORDERLY                           \
65  {                                                   \
66      if(NvClearOrderly() != TPM_RC_SUCCESS)          \
67          return g_NvStatus;                          \
68  }
69  #define NV_IS_AVAILABLE      (g_NvStatus == TPM_RC_SUCCESS)
70  #define IS_ORDERLY(value)    (value < SU_DA_USED_VALUE)
71  #define NV_IS_ORDERLY        (IS_ORDERLY(gp.orderlyState))
```

 Copyright © TCG 2006-2020

Macro to set the NV UPDATE_TYPE. This deals with the fact that the update is possibly a combination of UT_NV and UT_ORDERLY.

```
72    #define SET_NV_UPDATE(type)     g_updateNV |= (type)
73    #endif  // _NV_H_
```

 Copyright © TCG 2006-2020

5.15 TPMB.h

This file contains extra TPM2B structures

```
1    #ifndef _TPMB_H
2    #define _TPMB_H
```

TPM2B Types

```
3    typedef struct {
4        UINT16          size;
5        BYTE            buffer[1];
6    } TPM2B, *P2B;
7    typedef const TPM2B     *PC2B;
```

This macro helps avoid having to type in the structure in order to create a new TPM2B type that is used in a function.

```
8    #define TPM2B_TYPE(name, bytes)                 \
9        typedef union {                             \
10           struct  {                               \
11               UINT16  size;                       \
12               BYTE    buffer[(bytes)];            \
13           } t;                                    \
14           TPM2B   b;                              \
15       } TPM2B_##name
```

This macro defines a TPM2B with a constant character value. This macro sets the size of the string to the size minus the terminating zero byte. This lets the user of the label add their terminating 0. This method is chosen so that existing code that provides a label will continue to work correctly. Macro to instance and initialize a TPM2B value

```
16   #define TPM2B_INIT(TYPE, name)  \
17       TPM2B_##TYPE    name = {sizeof(name.t.buffer), {0}}
18   #define TPM2B_BYTE_VALUE(bytes) TPM2B_TYPE(bytes##_BYTE_VALUE, bytes)
19   #endif
```

5.16 Tpm.h

Root header file for building any TPM.lib code

```
1  #ifndef     _TPM_H_
2  #define     _TPM_H_
3  #include "TpmBuildSwitches.h"
4  #include "BaseTypes.h"
5  #include "TPMB.h"
6  #include "MinMax.h"
7  #include "TpmProfile.h"
8  #include "TpmAlgorithmDefines.h"
9  #include "LibSupport.h"         // Types from the library. These need to come before
10                                 // Global.h because some of the structures in
11                                 // that file depend on the structures used by the
12                                 // cryptographic libraries.
13 #include "GpMacros.h"           // Define additional macros
14 #include "Global.h"             // Define other TPM types
15 #include "InternalRoutines.h"   // Function prototypes
16 #endif // _TPM_H_
```

 Copyright © TCG 2006-2020

5.17 TpmBuildSwitches.h

This file contains the build switches. This contains switches for multiple versions of the crypto-library so some may not apply to your environment.

The switches are guarded so that they can either be set on the command line or set here. If the switch is listed on the command line (-DSOME_SWITCH) with NO setting, then the switch will be set to YES. If the switch setting is not on the command line or if the setting is other than YES or NO, then the switch will be set to the default value. The default can either be YES or NO as indicated on each line where the default is selected.

A caution. Do not try to test these macros by inserting #defines in this file. For some curious reason, a variable set on the command line with no setting will have a value of 1. An #if SOME_VARIABLE will work if the variable is not defined or is defined on the command line with no initial setting. However, a "#define SOME_VARIABLE" is a null string and when used in "#if SOME_VARIABLE" will not be a proper expression If you want to test various switches, either use the command line or change the default.

```
1   #ifndef _TPM_BUILD_SWITCHES_H_
2   #define _TPM_BUILD_SWITCHES_H_
3   #undef YES
4   #define YES 1
5   #undef NO
6   #define NO 0
```

Allow the command line to specify a **profile** file

```
7   #ifdef PROFILE
8   #   define PROFILE_QUOTE(a) #a
9   #   define PROFILE_INCLUDE(a) PROFILE_QUOTE(a)
10  #   include PROFILE_INCLUDE(PROFILE)
11  #endif
```

Need an unambiguous definition for DEBUG. Don't change this

```
12  #ifndef DEBUG
13  #   ifdef NDEBUG
14  #       define  DEBUG   NO
15  #   else
16  #       define  DEBUG   YES
17  #   endif
18  #elif (DEBUG != NO) && (DEBUG != YES)
19  #   undef   DEBUG
20  #   define  DEBUG                        YES     // Default: Either YES or NO
21  #endif
22  #include "CompilerDependencies.h"
```

This definition is required for the re-factored code

```
23  #if (!defined USE_BN_ECC_DATA)                                               \
24                  || ((USE_BN_ECC_DATA != NO) && (USE_BN_ECC_DATA != YES))
25  #   undef   USE_BN_ECC_DATA
26  #   define  USE_BN_ECC_DATA              YES     // Default: Either YES or NO
27  #endif
```

The SIMULATION switch allows certain other macros to be enabled. The things that can be enabled in a simulation include key caching, reproducible **random** sequences, instrumentation of the RSA key generation process, and certain other debug code. SIMULATION Needs to be defined as either YES or NO. This grouping of macros will make sure that it is set correctly. A simulated TPM would include a Virtual TPM. The interfaces for a Virtual TPM should be modified from the standard ones in the Simulator project.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

If SIMULATION is in the compile parameters without modifiers, make SIMULATION == YES

```
28  #if !(defined SIMULATION) || ((SIMULATION != NO) && (SIMULATION != YES))
29  #   undef   SIMULATION
30  #   define  SIMULATION                 YES     // Default: Either YES or NO
31  #endif
```

Define this to run the function that checks the compatibility between the chosen big number math library and the TPM code. Not all ports use this.

```
32  #if !(defined LIBRARY_COMPATIBILITY_CHECK)                                  \
33          || (( LIBRARY_COMPATIBILITY_CHECK != NO)                            \
34              && (LIBRARY_COMPATIBILITY_CHECK != YES))
35  #   undef   LIBRARY_COMPATIBILITY_CHECK
36  #   define  LIBRARY_COMPATIBILITY_CHECK YES     // Default: Either YES or NO
37  #endif
38  #if !(defined FIPS_COMPLIANT) || ((FIPS_COMPLIANT != NO) && (FIPS_COMPLIANT != YES))
39  #   undef   FIPS_COMPLIANT
40  #   define  FIPS_COMPLIANT             YES     // Default: Either YES or NO
41  #endif
```

Definition to allow alternate behavior for non-orderly startup. If there is a chance that the TPM could not update *failedTries*

```
42  #if !(defined USE_DA_USED) || ((USE_DA_USED != NO) && (USE_DA_USED != YES))
43  #   undef   USE_DA_USED
44  #   define  USE_DA_USED                YES     // Default: Either YES or NO
45  #endif
```

Define TABLE_DRIVEN_DISPATCH to use tables rather than case statements for command dispatch and handle unmarshaling

```
46  #if !(defined TABLE_DRIVEN_DISPATCH)                                        \
47          || ((TABLE_DRIVEN_DISPATCH != NO) && (TABLE_DRIVEN_DISPATCH != YES))
48  #   undef   TABLE_DRIVEN_DISPATCH
49  #   define  TABLE_DRIVEN_DISPATCH      YES     // Default: Either YES or NO
50  #endif
```

This switch is used to enable the self-test capability in AlgorithmTests.c

```
51  #if !(defined SELF_TEST) || ((SELF_TEST != NO) && (SELF_TEST != YES))
52  #   undef   SELF_TEST
53  #   define  SELF_TEST                  YES     // Default: Either YES or NO
54  #endif
```

Enable the generation of RSA primes using a sieve.

```
55  #if !(defined RSA_KEY_SIEVE) || ((RSA_KEY_SIEVE != NO) && (RSA_KEY_SIEVE != YES))
56  #   undef   RSA_KEY_SIEVE
57  #   define  RSA_KEY_SIEVE              YES     // Default: Either YES or NO
58  #endif
```

Enable the instrumentation of the sieve process. This is used to tune the sieve variables.

```
59  #if RSA_KEY_SIEVE && SIMULATION
60  #   if !(defined RSA_INSTRUMENT)                                            \
61              || ((RSA_INSTRUMENT != NO) && (RSA_INSTRUMENT != YES))
62  #       undef   RSA_INSTRUMENT
63  #       define  RSA_INSTRUMENT         NO      // Default: Either YES or NO
64  #   endif
65  #endif
```

This switch enables the RNG state save and restore

```
66  #if !(defined _DRBG_STATE_SAVE)                                                    \
67      || ((_DRBG_STATE_SAVE != NO) && (_DRBG_STATE_SAVE != YES))
68  #   undef    _DRBG_STATE_SAVE
69  #   define   _DRBG_STATE_SAVE           YES     // Default: Either YES or NO
70  #endif
```

Switch added to support packed lists that leave out space associated with unimplemented commands. Comment this out to use linear lists.

NOTE: if vendor specific commands are present, the associated list is always in compressed form.

```
71  #if !(defined COMPRESSED_LISTS)                                                    \
72      || ((COMPRESSED_LISTS != NO) && (COMPRESSED_LISTS != YES))
73  #   undef    COMPRESSED_LISTS
74  #   define   COMPRESSED_LISTS           YES     // Default: Either YES or NO
75  #endif
```

This switch indicates where clock epoch value should be stored. If this value defined, then it is assumed that the timer will change at any time so the nonce should be a random number kept in RAM. When it is not defined, then the timer only stops during power outages.

```
76  #if !(defined CLOCK_STOPS) || ((CLOCK_STOPS != NO) && (CLOCK_STOPS != YES))
77  #   undef    CLOCK_STOPS
78  #   define   CLOCK_STOPS                NO      // Default: Either YES or NO
79  #endif
```

This switch allows use of #defines in place of pass-through marshaling or unmarshaling code. A pass-through function just calls another function to do the required function and does no parameter checking of its own. The table-driven dispatcher calls directly to the lowest level marshaling/unmarshaling code and by-passes any pass-through functions.

```
80  #if (defined USE_MARSHALING_DEFINES) && (USE_MARSHALING_DEFINES != NO)
81  #   undef    USE_MARSHALING_DEFINES
82  #   define   USE_MARSHALING_DEFINES     YES
83  #else
84  #   define USE_MARSHALING_DEFINES      YES     // Default: Either YES or NO
85  #endif
```

The switches in this group can only be enabled when doing debug during simulation

```
86  #if SIMULATION && DEBUG
```

This forces the use of a smaller context slot size. This reduction reduces the range of the epoch allowing the tester to force the epoch to occur faster than the normal defined in TpmProfile.h

```
87  #   if !(defined CONTEXT_SLOT)
88  #       define CONTEXT_SLOT             UINT8
89  #   endif
```

Enables use of the key cache. Default is YES

```
90  #   if !(defined USE_RSA_KEY_CACHE)                                                \
91      || ((USE_RSA_KEY_CACHE != NO) && (USE_RSA_KEY_CACHE != YES))
92  #       undef    USE_RSA_KEY_CACHE
93  #       define   USE_RSA_KEY_CACHE      YES     // Default: Either YES or NO
94  #   endif
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

Enables use of a file to store the key cache values so that the TPM will start faster during debug. Default for this is YES

```
 95     #   if USE_RSA_KEY_CACHE
 96     #       if !(defined USE_KEY_CACHE_FILE)                                        \
 97                 || ((USE_KEY_CACHE_FILE != NO) && (USE_KEY_CACHE_FILE != YES))
 98     #           undef    USE_KEY_CACHE_FILE
 99     #           define   USE_KEY_CACHE_FILE  YES     // Default: Either YES or NO
100     #       endif
101     #   else
102     #       undef   USE_KEY_CACHE_FILE
103     #       define  USE_KEY_CACHE_FILE      NO
104     #   endif   // USE_RSA_KEY_CACHE
```

This provides fixed seeding of the RNG when doing debug on a simulator. This should allow consistent results on test runs as long as the input parameters to the functions remains the same. There is no default value.

```
105     #   if !(defined USE_DEBUG_RNG) || ((USE_DEBUG_RNG != NO) && (USE_DEBUG_RNG != YES))
106     #       undef   USE_DEBUG_RNG
107     #       define  USE_DEBUG_RNG           YES     // Default: Either YES or NO
108     #   endif
```

Don't change these. They are the settings needed when not doing a simulation and not doing debug. Can't use the key cache except during debug. Otherwise, all of the key values end up being the same

```
109     #else
110     #   define USE_RSA_KEY_CACHE           NO
111     #   define USE_RSA_KEY_CACHE_FILE      NO
112     #   define USE_DEBUG_RNG               NO
113     #endif  // DEBUG && SIMULATION
114     #if DEBUG
```

In some cases, the relationship between two values may be dependent on things that change based on various selections like the chosen cryptographic libraries. It is possible that these selections will result in incompatible settings. These are often detectable by the compiler but it isn't always possible to do the check in the preprocessor code. For example, when the check requires use of 'sizeof()' then the preprocessor can't do the comparison. For these cases, we include a special macro that, depending on the compiler will generate a warning to indicate if the check always passes or always fails because it involves fixed constants. To run these checks, define COMPILER_CHECKS.

```
115     #   if !(defined COMPILER_CHECKS)                                           \
116             || ((COMPILER_CHECKS != NO) && (COMPILER_CHECKS != YES))
117     #       undef   COMPILER_CHECKS
118     #       define  COMPILER_CHECKS         NO      // Default: Either YES or NO
119     #   endif
```

Some of the values (such as sizes) are the result of different options set in TpmProfile.h. The combination might not be consistent. A function is defined (TpmSizeChecks()) that is used to verify the sizes at run time. To enable the function, define this parameter.

```
120     #   if !(defined RUNTIME_SIZE_CHECKS)                                       \
121         || ((RUNTIME_SIZE_CHECKS != NO) && (RUNTIME_SIZE_CHECKS != YES))
122     #       undef RUNTIME_SIZE_CHECKS
123     #       define RUNTIME_SIZE_CHECKS      YES      // Default: Either YES or NO
124     #   endif
```

If doing debug, can set the DRBG to print out the intermediate test values. Before enabling this, make sure that the dbgDumpMemBlock() function has been added someplace (preferably, somewhere in CryptRand.c)

```
125  #   if !(defined DRBG_DEBUG_PRINT)                                                    \
126      || ((DRBG_DEBUG_PRINT != NO) && (DRBG_DEBUG_PRINT != YES))
127  #       undef   DRBG_DEBUG_PRINT
128  #       define  DRBG_DEBUG_PRINT        NO      // Default: Either YES or NO
129  #   endif
```

If an assertion event it not going to produce any trace information (function and line number) then make FAIL_TRACE == NO

```
130  #   if !(defined FAIL_TRACE) || ((FAIL_TRACE != NO) && (FAIL_TRACE != YES))
131  #       undef   FAIL_TRACE
132  #       define  FAIL_TRACE              YES     // Default: Either YES or NO
133  #   endif
134  #endif // DEBUG
```

Indicate if the implementation is going to give lockout time credit for time up to the last orderly shutdown.

```
135  #if !(defined ACCUMULATE_SELF_HEAL_TIMER)                                                 \
136      || ((ACCUMULATE_SELF_HEAL_TIMER != NO) && (ACCUMULATE_SELF_HEAL_TIMER != YES))
137  #   undef   ACCUMULATE_SELF_HEAL_TIMER
138  #   define  ACCUMULATE_SELF_HEAL_TIMER  YES     // Default: Either YES or NO
139  #endif
```

Indicates if the implementation is to compute the sizes of the proof and primary seed size values based on the implemented algorithms.

```
140  #if !(defined USE_SPEC_COMPLIANT_PROOFS)                                                  \
141      || ((USE_SPEC_COMPLIANT_PROOFS != NO) && (USE_SPEC_COMPLIANT_PROOFS != YES))
142  #   undef   USE_SPEC_COMPLIANT_PROOFS
143  #   define  USE_SPEC_COMPLIANT_PROOFS   YES     // Default: Either YES or NO
144  #endif
```

Comment this out to allow compile to continue even though the chosen proof values do not match the compliant values. This is written so that someone would have to proactively ignore errors.

```
145  #if !(defined SKIP_PROOF_ERRORS)                                                          \
146      || ((SKIP_PROOF_ERRORS != NO) && (SKIP_PROOF_ERRORS != YES))
147  #   undef   SKIP_PROOF_ERRORS
148  #   define  SKIP_PROOF_ERRORS           NO      // Default: Either YES or NO
149  #endif
```

This define is used to eliminate the use of bit-fields. It can be enabled for big- or little-endian machines. For big-endian architectures that numbers bits in registers from left to right (MSb0) this must be enabled. Little-endian machines number from right to left with the least significant bit having assigned a bit number of 0. These are LSb0 machines (they are also little-endian so they are also least-significant byte 0 (LSB0) machines. Big-endian (MSB0) machines may number in either direction (MSb0 or LSb0). For an MSB0+MSb0 machine this value is required to be *NO*

```
150  #if !(defined USE_BIT_FIELD_STRUCTURES)                                                   \
151      || ((USE_BIT_FIELD_STRUCTURES != NO) && (USE_BIT_FIELD_STRUCTURES != YES))
152  #   undef   USE_BIT_FIELD_STRUCTURES
153  #   define  USE_BIT_FIELD_STRUCTURES    DEBUG       // Default: Either YES or NO
154  #endif
```

This define is used to control the debug for the CertifyX509() command.

```
155  #if !(defined CERTIFYX509_DEBUG)                                                          \
156      || ((CERTIFYX509_DEBUG != NO) && (CERTIFYX509_DEBUG != YES))
157  #   undef   CERTIFYX509_DEBUG
158  #   define  CERTIFYX509_DEBUG YES               // Default: Either YES or NO
159  #endif
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

This define is used to enable the new table-driven marshaling code.

```
160  #if !(defined TABLE_DRIVEN_MARSHAL)                                              \
161      || ((TABLE_DRIVEN_MARSHAL != NO) && (TABLE_DRIVEN_MARSHAL != YES))
162  #   undef   TABLE_DRIVEN_MARSHAL
163  #   define  TABLE_DRIVEN_MARSHAL YES    // Default: Either YES or NO
164  #endif
```

Change these definitions to turn all algorithms or commands ON or OFF. That is, to turn all algorithms on, set ALG_NO to YES. This is mostly useful as a debug feature.

```
165  #define      ALG_YES      YES
166  #define      ALG_NO       NO
167  #define      CC_YES       YES
168  #define      CC_NO        NO
169  #endif // _TPM_BUILD_SWITCHES_H_
```

5.20 VendorString.h

```
1   #ifndef      _VENDOR_STRING_H
2   #define      _VENDOR_STRING_H
```

Define up to 4-byte values for MANUFACTURER. This value defines the response for TPM_PT_MANUFACTURER in TPM2_GetCapability(). The following line should be un-commented and a vendor specific string should be provided here.

```
3   #define     MANUFACTURER     "MSFT"
```

The following #if macro may be deleted after a proper MANUFACTURER is provided.

```
4   #ifndef MANUFACTURER
5   #error MANUFACTURER is not provided. \
6   Please modify include/VendorString.h to provide a specific \
7   manufacturer name.
8   #endif
```

Define up to 4, 4-byte values. The values must each be 4 bytes long and the last value used may contain trailing zeros. These values define the response for TPM_PT_VENDOR_STRING_(1-4) in TPM2_GetCapability(). The following line should be un-commented and a vendor specific string should be provided here. The vendor strings 2-4 may also be defined as appropriate.

```
9   #define        VENDOR_STRING_1        "xCG "
10  #define        VENDOR_STRING_2        "fTPM"
11  // #define        VENDOR_STRING_3
12  // #define        VENDOR_STRING_4
```

The following #if macro may be deleted after a proper VENDOR_STRING_1 is provided.

```
13  #ifndef VENDOR_STRING_1
14  #error VENDOR_STRING_1 is not provided. \
15  Please modify include/VendorString.h to provide a vendor-specific string.
16  #endif
```

the more significant 32-bits of a vendor-specific value indicating the version of the firmware The following line should be un-commented and a vendor specific firmware V1 should be provided here. The FIRMWARE_V2 may also be defined as appropriate.

```
17  #define    FIRMWARE_V1          (0x20170619)
```

the less significant 32-bits of a vendor-specific value indicating the version of the firmware

```
18  #define    FIRMWARE_V2          (0x00163636)
```

The following #if macro may be deleted after a proper FIRMWARE_V1 is provided.

```
19  #ifndef FIRMWARE_V1
20  #error  FIRMWARE_V1 is not provided. \
21  Please modify include/VendorString.h to provide a vendor-specific firmware \
22  version
23  #endif
24  #endif
```

6 Main

6.1 Introduction

The files in this section are the main processing blocks for the TPM. ExecuteCommand.c contains the entry point into the TPM code and the parsing of the command header. SessionProcess.c handles the parsing of the session area and the authorization checks, and CommandDispatch.c does the parameter unmarshaling and command dispatch.

6.2 ExecCommand.c

6.2.1 Introduction

This file contains the entry function ExecuteCommand() which provides the main control flow for TPM command execution.

6.2.2 Includes

```
1   #include "Tpm.h"
2   #include "ExecCommand_fp.h"
```

Uncomment this next #include if doing static command/response buffer sizing

```
3   // #include "CommandResponseSizes_fp.h"
```

6.2.3 ExecuteCommand()

The function performs the following steps.

 Copyright © TCG 2006-2020

a) Parses the command header from input buffer.

b) Calls ParseHandleBuffer() to parse the handle area of the command.

c) Validates that each of the handles references a loaded entity.

d) Calls ParseSessionBuffer() () to:

   1) unmarshal and parse the session area;

   2) check the authorizations; and

   3) when necessary, decrypt a parameter.

e) Calls CommandDispatcher() to:

   1) unmarshal the command parameters from the command buffer;

   2) call the routine that performs the command actions; and

   3) marshal the responses into the response buffer.

f) If any error occurs in any of the steps above create the error response and return.

g) Calls BuildResponseSessions() to:

   1) when necessary, encrypt a parameter

   2) build the response authorization sessions

   3) update the audit sessions and nonces

h) Calls BuildResponseHeader() to complete the construction of the response.

responseSize is set by the caller to the maximum number of bytes available in the output buffer. ExecuteCommand() will adjust the value and return the number of bytes placed in the buffer.

response is also set by the caller to indicate the buffer into which ExecuteCommand() is to place the response.

request and *response* may point to the same buffer

NOTE: As of February, 2016, the failure processing has been moved to the platform-specific code. When the TPM code encounters an unrecoverable failure, it will SET *g_inFailureMode* and call _plat__Fail(). That function should not return but may call ExecuteCommand().

```
4   LIB_EXPORT void
5   ExecuteCommand(
6       uint32_t          requestSize,    // IN: command buffer size
7       unsigned char    *request,        // IN: command buffer
8       uint32_t         *responseSize,   // IN/OUT: response buffer size
9       unsigned char    **response       // IN/OUT: response buffer
10      )
11  {
12      // Command local variables
13      UINT32                commandSize;
14      COMMAND               command;
15
16      // Response local variables

6.3 CommandDispatcher.c

6.3.1 Introduction

CommandDispatcher() performs the following operations:

- unmarshals command parameters from the input buffer;

NOTE 1 Unlike other unmarshaling functions, *parmBufferStart* does not advance. *parmBufferSize* Is reduced.

- invokes the function that performs the command actions;
- marshals the returned handles, if any; and
- marshals the returned parameters, if any, into the output buffer putting in the *parameterSize* field if authorization sessions are present.

NOTE 2 The output buffer is the return from the MemoryGetResponseBuffer() function. It includes the header, handles, response parameters, and authorization area. *respParmSize* is the response parameter size, and does not include the header, handles, or authorization area.

NOTE 3 The reference implementation is permitted to do compare operations over a union as a byte array. Therefore, the command parameter *in* structure must be initialized (e.g., zeroed) before unmarshaling so that the compare operation is valid in cases where some bytes are unused.

6.3.1.1 Includes and Typedefs

```
1  #include "Tpm.h"
2  #include "Marshal.h"
3  #if TABLE_DRIVEN_DISPATCH
4  typedef TPM_RC(NoFlagFunction)(void *target, BYTE **buffer, INT32 *size);
5  typedef TPM_RC(FlagFunction)(void *target, BYTE **buffer, INT32 *size, BOOL flag);
6  typedef FlagFunction *UNMARSHAL_t;
7  typedef INT16(MarshalFunction)(void *source, BYTE **buffer, INT32 *size);
8  typedef MarshalFunction *MARSHAL_t;
9  typedef TPM_RC(COMMAND_NO_ARGS)(void);
10 typedef TPM_RC(COMMAND_IN_ARG)(void *in);
11 typedef TPM_RC(COMMAND_OUT_ARG)(void *out);
12 typedef TPM_RC(COMMAND_INOUT_ARG)(void *in, void *out);
13 typedef union COMMAND_t
14 {
15     COMMAND_NO_ARGS          *noArgs;
16     COMMAND_IN_ARG           *inArg;
17     COMMAND_OUT_ARG          *outArg;
18     COMMAND_INOUT_ARG        *inOutArg;
19 } COMMAND_t;
```

This structure is used by ParseHandleBuffer() and CommandDispatcher(). The parameters in this structure are unique for each command. The parameters are:

 Copyright © TCG 2006-2020

command	**holds the address of the command processing function that is called by Command Dispatcher.**
inSize	this is the size of the command-dependent input structure. The input structure holds the unmarshaled handles and command parameters. If the command takes no arguments (handles or parameters) then *inSize* will have a value of 0.
outSize	this is the size of the command-dependent output structure. The output structure holds the results of the command in an unmarshaled form. When command processing is completed, these values are marshaled into the output buffer. It is always the case that the unmarshaled version of an output structure is larger then the marshaled version. This is because the marshaled version contains the exact same number of significant bytes but with padding removed.
typesOffsets	this parameter points to the list of data types that are to be marshaled or unmarshaled. The list of types follows the *offsets* array. The offsets array is variable sized so the *typesOffset* filed is necessary for the handle and command processing to be able to find the types that are being handled. The *offsets* array may be empty. The types structure is described below.
offsets	this is an array of offsets of each of the parameters in the command or response. When processing the command parameters (not handles) the list contains the offset of the next parameter. For example, if the first command parameter has a size of 4 and there is a second command parameter, then the offset would be 4, indicating that the second parameter starts at 4. If the second parameter has a size of 8, and there is a third parameter, then the second entry in offsets is 12 (4 for the first parameter and 8 for the second). An offset value of 0 in the list indicates the start of the response parameter list. When CommandDispatcher() hits this value, it will stop unmarshaling the parameters and call *command*. If a command has no response parameters and only one command parameter, then offsets can be an empty list.

```
20  typedef struct COMMAND_DESCRIPTOR_t
21  {
22      COMMAND_t       command;        // Address of the command
23      UINT16          inSize;         // Maximum size of the input structure
24      UINT16          outSize;        // Maximum size of the output structure
25      UINT16          typesOffset;    // address of the types field
26      UINT16          offsets[1];
27  } COMMAND_DESCRIPTOR_t;
```

The *types* list is an encoded byte array. The byte value has two parts. The most significant bit is used when a parameter takes a flag and indicates if the flag should be SET or not. The remaining 7 bits are an index into an array of addresses of marshaling and unmarshaling functions. The array of functions is divided into 6 sections with a value assigned to denote the start of that section (and the end of the previous section). The defined offset values for each section are:

 Copyright © TCG 2006-2020

0	unmarshaling for handles that do not take flags
HANDLE_FIRST_FLAG_TYPE	unmarshaling for handles that take flags
PARAMETER_FIRST_TYPE	unmarshaling for parameters that do not take flags
PARAMETER_FIRST_FLAG_TYPE	unmarshaling for parameters that take flags
1	marshaling for handles
RESPONSE_PARAMETER_FIRST_TYPE	marshaling for parameters
RESPONSE_PARAMETER_LAST_TYPE	is the last value in the list of marshaling and unmarshaling functions.

The types list is constructed with a byte of 0xff at the end of the command parameters and with an 0xff at the end of the response parameters.

```

6.4 SessionProcess.c

6.4.1 Introduction

This file contains the subsystem that process the authorization sessions including implementation of the Dictionary Attack logic. ExecCommand() uses ParseSessionBuffer() to process the authorization session area of a command and BuildResponseSession() to create the authorization session area of a response.

6.4.2 Includes and Data Definitions

```
1   #define SESSION_PROCESS_C
2   #include "Tpm.h"
3   #include "ACT.h"
```

6.4.3 Authorization Support Functions

6.4.3.1 IsDAExempted()

This function indicates if a handle is exempted from DA logic. A handle is exempted if it is

a) a primary seed handle,

b) an object with *noDA* bit SET,

c) an NV Index with TPMA_NV_NO_DA bit SET, or

d) a PCR handle.

Return Value	Meaning
TRUE(1)	handle is exempted from DA logic
FALSE(0)	handle is not exempted from DA logic

```
4   BOOL
5   IsDAExempted(
6       TPM_HANDLE       handle         // IN: entity handle
7       )
8   {
9       BOOL         result = FALSE;
10  //
11      switch(HandleGetType(handle))
12      {
13          case TPM_HT_PERMANENT:
14              // All permanent handles, other than TPM_RH_LOCKOUT, are exempt from
15              // DA protection.
16              result = (handle != TPM_RH_LOCKOUT);
17              break;
18          // When this function is called, a persistent object will have been loaded
19          // into an object slot and assigned a transient handle.
20          case TPM_HT_TRANSIENT:
21          {
22              TPMA_OBJECT     attributes = ObjectGetPublicAttributes(handle);
23              result = IS_ATTRIBUTE(attributes, TPMA_OBJECT, noDA);
24              break;
25          }
26          case TPM_HT_NV_INDEX:
27          {
28              NV_INDEX             *nvIndex = NvGetIndexInfo(handle, NULL);
29              result = IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, NO_DA);
30              break;
```

 Copyright © TCG 2006-2020

```
31          }
32          case TPM_HT_PCR:
33              // PCRs are always exempted from DA.
34              result = TRUE;
35              break;
36          default:
37              break;
38      }
39      return result;
40  }
```

6.4.3.2 IncrementLockout()

This function is called after an authorization failure that involves use of an *authValue*. If the entity referenced by the handle is not exempt from DA protection, then the *failedTries* counter will be incremented.

Error Returns	Meaning
TPM_RC_AUTH_FAIL	authorization failure that caused DA lockout to increment
TPM_RC_BAD_AUTH	authorization failure did not cause DA lockout to increment

```
41  static TPM_RC
42  IncrementLockout(
43      UINT32              sessionIndex
44      )
45  {
46      TPM_HANDLE          handle = s_associatedHandles[sessionIndex];
47      TPM_HANDLE          sessionHandle = s_sessionHandles[sessionIndex];
48      SESSION            *session = NULL;
49  //
50      // Don't increment lockout unless the handle associated with the session
51      // is DA protected or the session is bound to a DA protected entity.
52      if(sessionHandle == TPM_RS_PW)
53      {
54          if(IsDAExempted(handle))
55              return TPM_RC_BAD_AUTH;
56      }
57      else
58      {
59          session = SessionGet(sessionHandle);
60          // If the session is bound to lockout, then use that as the relevant
61          // handle. This means that an authorization failure with a bound session
62          // bound to lockoutAuth will take precedence over any other
63          // lockout check
64          if(session->attributes.isLockoutBound == SET)
65              handle = TPM_RH_LOCKOUT;
66          if(session->attributes.isDaBound == CLEAR
67             && (IsDAExempted(handle) || session->attributes.includeAuth == CLEAR))
68             // If the handle was changed to TPM_RH_LOCKOUT, this will not return
69             // TPM_RC_BAD_AUTH
70              return TPM_RC_BAD_AUTH;
71      }
72      if(handle == TPM_RH_LOCKOUT)
73      {
74          pAssert(gp.lockOutAuthEnabled == TRUE);
75
76          // lockout is no longer enabled
77          gp.lockOutAuthEnabled = FALSE;
78
79          // For TPM_RH_LOCKOUT, if lockoutRecovery is 0, no need to update NV since
80          // the lockout authorization will be reset at startup.
81          if(gp.lockoutRecovery != 0)
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
82          {
83              if(NV_IS_AVAILABLE)
84                  // Update NV.
85                  NV_SYNC_PERSISTENT(lockOutAuthEnabled);
86              else
87                  // No NV access for now. Put the TPM in pending mode.
88                  s_DAPendingOnNV = TRUE;
89          }
90      }
91      else
92      {
93          if(gp.recoveryTime != 0)
94          {
95              gp.failedTries++;
96              if(NV_IS_AVAILABLE)
97                  // Record changes to NV. NvWrite will SET g_updateNV
98                  NV_SYNC_PERSISTENT(failedTries);
99              else
100                 // No NV access for now.  Put the TPM in pending mode.
101                 s_DAPendingOnNV = TRUE;
102         }
103     }
104     // Register a DA failure and reset the timers.
105     DARegisterFailure(handle);
106
107     return TPM_RC_AUTH_FAIL;
108 }
```

6.4.3.3 IsSessionBindEntity()

This function indicates if the entity associated with the handle is the entity, to which this session is bound. The binding would occur by making the **bind** parameter in TPM2_StartAuthSession() not equal to TPM_RH_NULL. The binding only occurs if the session is an HMAC session. The bind value is a combination of the Name and the *authValue* of the entity.

Return Value	Meaning
TRUE(1)	handle points to the session start entity
FALSE(0)	handle does not point to the session start entity

```
109 static BOOL
110 IsSessionBindEntity(
111     TPM_HANDLE       associatedHandle,  // IN: handle to be authorized
112     SESSION         *session            // IN: associated session
113     )
114 {
115     TPM2B_NAME     entity;             // The bind value for the entity
116 //
117     // If the session is not bound, return FALSE.
118     if(session->attributes.isBound)
119     {
120         // Compute the bind value for the entity.
121         SessionComputeBoundEntity(associatedHandle, &entity);
122
123         // Compare to the bind value in the session.
124         return MemoryEqual2B(&entity.b, &session->u1.boundEntity.b);
125     }
126     return FALSE;
127 }
```

6.4.3.4 IsPolicySessionRequired()

Checks if a policy session is required for a command. If a command requires DUP or ADMIN role authorization, then the handle that requires that role is the first handle in the command. This simplifies this checking. If a new command is created that requires multiple ADMIN role authorizations, then it will have to be special-cased in this function. A policy session is required if:

a) the command requires the DUP role,

b) the command requires the ADMIN role and the authorized entity is an object and its *adminWithPolicy* bit is SET, or

c) the command requires the ADMIN role and the authorized entity is a permanent handle or an NV Index.

d) The authorized entity is a PCR belonging to a policy group, and has its policy initialized

Return Value	Meaning
TRUE(1)	policy session is required
FALSE(0)	policy session is not required

```
128 static BOOL
129 IsPolicySessionRequired(
130     COMMAND_INDEX    commandIndex,  // IN: command index
131     UINT32           sessionIndex   // IN: session index
132     )
133 {
134     AUTH_ROLE       role = CommandAuthRole(commandIndex, sessionIndex);
135     TPM_HT          type = HandleGetType(s_associatedHandles[sessionIndex]);
136 //
137     if(role == AUTH_DUP)
138         return TRUE;
139     if(role == AUTH_ADMIN)
140     {
141         // We allow an exception for ADMIN role in a transient object. If the object
142         // allows ADMIN role actions with authorization, then policy is not
143         // required. For all other cases, there is no way to override the command
144         // requirement that a policy be used
145         if(type == TPM_HT_TRANSIENT)
146         {
147             OBJECT      *object = HandleToObject(s_associatedHandles[sessionIndex]);
148
149             if(!IS_ATTRIBUTE(object->publicArea.objectAttributes, TPMA_OBJECT,
150                              adminWithPolicy))
151                 return FALSE;
152         }
153         return TRUE;
154     }
155
156     if(type == TPM_HT_PCR)
157     {
158         if(PCRPolicyIsAvailable(s_associatedHandles[sessionIndex]))
159         {
160             TPM2B_DIGEST        policy;
161             TPMI_ALG_HASH       policyAlg;
162             policyAlg = PCRGetAuthPolicy(s_associatedHandles[sessionIndex],
163                                          &policy);
164             if(policyAlg != TPM_ALG_NULL)
165                 return TRUE;
166         }
167     }
168     return FALSE;
169 }
```

6.4.3.5 IsAuthValueAvailable()

This function indicates if *authValue* is available and allowed for USER role authorization of an entity.

This function is similar to IsAuthPolicyAvailable() except that it does not check the size of the *authValue* as IsAuthPolicyAvailable() does (a null *authValue* is a valid authorization, but a null policy is not a valid policy).

This function does not check that the handle reference is valid or if the entity is in an enabled hierarchy. Those checks are assumed to have been performed during the handle unmarshaling.

Return Value	Meaning
TRUE(1)	*authValue* is available
FALSE(0)	*authValue* is not available

```
170  static BOOL
171  IsAuthValueAvailable(
172      TPM_HANDLE        handle,         // IN: handle of entity
173      COMMAND_INDEX     commandIndex,   // IN: command index
174      UINT32            sessionIndex    // IN: session index
175      )
176  {
177      BOOL              result = FALSE;
178  //
179      switch(HandleGetType(handle))
180      {
181          case TPM_HT_PERMANENT:
182              switch(handle)
183              {
184                      // At this point hierarchy availability has already been
185                      // checked so primary seed handles are always available here
186                  case TPM_RH_OWNER:
187                  case TPM_RH_ENDORSEMENT:
188                  case TPM_RH_PLATFORM:
189  #ifdef VENDOR_PERMANENT
190                      // This vendor defined handle associated with the
191                      // manufacturer's shared secret
192                  case VENDOR_PERMANENT:
193  #endif
194                      // The DA checking has been performed on LockoutAuth but we
195                      // bypass the DA logic if we are using lockout policy. The
196                      // policy would allow execution to continue an lockoutAuth
197                      // could be used, even if direct use of lockoutAuth is disabled
198                  case TPM_RH_LOCKOUT:

6.4.3.6 IsAuthPolicyAvailable()

This function indicates if an *authPolicy* is available and allowed.

This function does not check that the handle reference is valid or if the entity is in an enabled hierarchy. Those checks are assumed to have been performed during the handle unmarshaling.

Return Value	Meaning
TRUE(1)	*authPolicy* is available
FALSE(0)	*authPolicy* is not available

```
294 static BOOL

523         CryptDigestUpdateInt(&hashState, sizeof(TPM_CC), command->code);
524             //  Add authNames for each of the handles.
525         for(i = 0; i < command->handleNum; i++)
526             CryptDigestUpdate2B(&hashState, &EntityGetName(command->handles[i],
527                                                            &name)->b);
528             //  Add the parameters.
529         CryptDigestUpdate(&hashState, command->parameterSize,
530                           command->parameterBuffer);
531             //  Complete the hash.
532         CryptHashEnd2B(&hashState, &cpHash->b);
533     }
534     return cpHash;
535 }
```

6.4.4.5 GetCpHash()

This function is used to access a precomputed *cpHash*.

```
536 static TPM2B_DIGEST *
537 GetCpHash(
538     COMMAND          *command,
539     TPMI_ALG_HASH     hashAlg
540     )
541 {
542     TPM2B_DIGEST         *cpHash = GetCpHashPointer(command, hashAlg);
543  //
544     pAssert(cpHash->t.size != 0);
545     return cpHash;
546 }
```

6.4.4.6 CompareTemplateHash()

This function computes the template hash and compares it to the session *templateHash*. It is the hash of the second parameter assuming that the command is TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded()

Return Value	Meaning
TRUE(1)	template hash equal to session->*templateHash*
FALSE(0)	template hash not equal to session->*templateHash*

```
547 static BOOL
548 CompareTemplateHash(
549     COMMAND          *command,        // IN: parsing structure
```

```
550     SESSION         *session        // IN: session data
551     )
552 {
553     BYTE                *pBuffer = command->parameterBuffer;
554     INT32                pSize = command->parameterSize;
555     TPM2B_DIGEST         tHash;
556     UINT16               size;
557 //
558     // Only try this for the three commands for which it is intended
559     if(command->code != TPM_CC_Create
560        && command->code != TPM_CC_CreatePrimary
561 #if CC_CreateLoaded
562        && command->code != TPM_CC_CreateLoaded
563 #endif
564        )
565         return FALSE;
566     // Assume that the first parameter is a TPM2B and unmarshal the size field
567     // Note: this will not affect the parameter buffer and size in the calling
568     // function.
569     if(UINT16_Unmarshal(&size, &pBuffer, &pSize) != TPM_RC_SUCCESS)
570         return FALSE;
571     // reduce the space in the buffer.
572     // NOTE: this could make pSize go negative if the parameters are not correct but
573     // the unmarshaling code does not try to unmarshal if the remaining size is
574     // negative.
575     pSize -= size;
576
577     // Advance the pointer
578     pBuffer += size;
579
580     // Get the size of what should be the template
581     if(UINT16_Unmarshal(&size, &pBuffer, &pSize) != TPM_RC_SUCCESS)
582         return FALSE;
583     // See if this is reasonable
584     if(size > pSize)
585         return FALSE;
586     // Hash the template data
587     tHash.t.size = CryptHashBlock(session->authHashAlg, size, pBuffer,
588                                   sizeof(tHash.t.buffer), tHash.t.buffer);
589     return(MemoryEqual2B(&session->u1.templateHash.b, &tHash.b));
590 }
```

6.4.4.7 CompareNameHash()

This function computes the name hash and compares it to the *nameHash* in the session data.

```
591 BOOL
592 CompareNameHash(
593     COMMAND         *command,       // IN: main parsing structure
594     SESSION         *session        // IN: session structure with nameHash
595     )
596 {
597     HASH_STATE           hashState;
598     TPM2B_DIGEST         nameHash;
599     UINT32               i;
600     TPM2B_NAME           name;
601 //
602     nameHash.t.size = CryptHashStart(&hashState, session->authHashAlg);
603     //  Add names.
604     for(i = 0; i < command->handleNum; i++)
605         CryptDigestUpdate2B(&hashState, &EntityGetName(command->handles[i],
606                                                        &name)->b);
607     //  Complete hash.
608     CryptHashEnd2B(&hashState, &nameHash.b);
```

 Copyright © TCG 2006-2020

```
609         // and compare
610         return MemoryEqual(session->u1.nameHash.t.buffer, nameHash.t.buffer,
611                            nameHash.t.size);
612     }
```

6.4.4.8 CheckPWAuthSession()

This function validates the authorization provided in a PWAP session. It compares the input value to *authValue* of the authorized entity. Argument *sessionIndex* is used to get handles handle of the referenced entities from *s_inputAuthValues*[] and *s_associatedHandles*[].

Error Returns	Meaning
TPM_RC_AUTH_FAIL	authorization fails and increments DA failure count
TPM_RC_BAD_AUTH	authorization fails but DA does not apply

```
613     static TPM_RC
614     CheckPWAuthSession(
615         UINT32           sessionIndex   // IN: index of session to be processed
616         )
617     {
618         TPM2B_AUTH      authValue;
619         TPM_HANDLE      associatedHandle = s_associatedHandles[sessionIndex];
620     //
621         // Strip trailing zeros from the password.
622         MemoryRemoveTrailingZeros(&s_inputAuthValues[sessionIndex]);
623
624         // Get the authValue with trailing zeros removed
625         EntityGetAuthValue(associatedHandle, &authValue);
626
627         // Success if the values are identical.
628         if(MemoryEqual2B(&s_inputAuthValues[sessionIndex].b, &authValue.b))
629         {
630             return TPM_RC_SUCCESS;
631         }
632         else                        // if the digests are not identical
633         {
634             // Invoke DA protection if applicable.
635             return IncrementLockout(sessionIndex);
636         }
637     }
```

6.4.4.9 ComputeCommandHMAC()

This function computes the HMAC for an authorization session in a command.

```
638     static TPM2B_DIGEST *
639     ComputeCommandHMAC(
640         COMMAND         *command,       // IN: primary control structure
641         UINT32           sessionIndex,  // IN: index of session to be processed
642         TPM2B_DIGEST    *hmac           // OUT: authorization HMAC
643         )
644     {
645         TPM2B_TYPE(KEY, (sizeof(AUTH_VALUE) * 2));
646         TPM2B_KEY        key;
647         BYTE             marshalBuffer[sizeof(TPMA_SESSION)];
648         BYTE            *buffer;
649         UINT32           marshalSize;
650         HMAC_STATE       hmacState;
651         TPM2B_NONCE     *nonceDecrypt;
652         TPM2B_NONCE     *nonceEncrypt;
653         SESSION         *session;
```

 Copyright © TCG 2006-2020

```

736
737         return hmac;
738     }
```

6.4.4.10 CheckSessionHMAC()

This function checks the HMAC of in a session. It uses ComputeCommandHMAC() to compute the expected HMAC value and then compares the result with the HMAC in the authorization session. The authorization is successful if they are the same.

If the authorizations are not the same, IncrementLockout() is called. It will return TPM_RC_AUTH_FAIL if the failure caused the *failureCount* to increment. Otherwise, it will return TPM_RC_BAD_AUTH.

Error Returns	Meaning
TPM_RC_AUTH_FAIL	authorization failure caused *failureCount* increment
TPM_RC_BAD_AUTH	authorization failure did not cause *failureCount* increment

```
739     static TPM_RC
740     CheckSessionHMAC(
741         COMMAND         *command,       // IN: primary control structure
742         UINT32           sessionIndex   // IN: index of session to be processed
743         )
744     {
745         TPM2B_DIGEST         hmac;           // authHMAC for comparing
746     //
747         // Compute authHMAC
748         ComputeCommandHMAC(command, sessionIndex, &hmac);
749
750         // Compare the input HMAC with the authHMAC computed above.
751         if(!MemoryEqual2B(&s_inputAuthValues[sessionIndex].b, &hmac.b))
752         {
753             // If an HMAC session has a failure, invoke the anti-hammering
754             // if it applies to the authorized entity or the session.
755             // Otherwise, just indicate that the authorization is bad.
756             return IncrementLockout(sessionIndex);
757         }
758         return TPM_RC_SUCCESS;
759     }
```

6.4.4.11 CheckPolicyAuthSession()

This function is used to validate the authorization in a policy session. This function performs the following comparisons to see if a policy authorization is properly provided. The check are:

a) compare *policyDigest* in session with *authPolicy* associated with the entity to be authorized;
b) compare timeout if applicable;
c) compare *commandCode* if applicable;
d) compare *cpHash* if applicable; and
e) see if PCR values have changed since computed.

If all the above checks succeed, the handle is authorized. The order of these comparisons is not important because any failure will result in the same error code.

Error Returns	Meaning
TPM_RC_PCR_CHANGED	PCR value is not current
TPM_RC_POLICY_FAIL	policy session fails
TPM_RC_LOCALITY	command locality is not allowed
TPM_RC_POLICY_CC	CC doesn't match
TPM_RC_EXPIRED	policy session has expired
TPM_RC_PP	PP is required but not asserted
TPM_RC_NV_UNAVAILABLE	NV is not available for write
TPM_RC_NV_RATE	NV is rate limiting

```
760  static TPM_RC
761  CheckPolicyAuthSession(
762      COMMAND          *command,       // IN: primary parsing structure

6.4.4.17 CheckAuthNoSession()

Function to process a command with no session associated. The function makes sure all the handles in the command require no authorization.

Error Returns	Meaning
TPM_RC_AUTH_MISSING	failure - one or more handles require authorization

```
1404    TPM_RC
1405    CheckAuthNoSession(
1406        COMMAND          *command        // IN: command parsing structure
1407        )
1408    {
1409        UINT32 i;
1410        TPM_RC           result = TPM_RC_SUCCESS;
1411    //
1412        // Check if the command requires authorization
1413        for(i = 0; i < command->handleNum; i++)
1414        {
1415            if(CommandAuthRole(command->index, i) != AUTH_NONE)
1416                return TPM_RC_AUTH_MISSING;
1417        }
1418    #ifdef  TPM_CC_GetCommandAuditDigest
1419        // Check if the command should be audited.
1420        if(CommandAuditIsRequired(command->index))
1421        {
1422            result = CheckCommandAudit(command);
```

```
1423            if(result != TPM_RC_SUCCESS)
1424                return result;
1425        }
1426    #endif
1427        // Initialize number of sessions to be 0
1428        command->sessionNum = 0;
1429
1430        return TPM_RC_SUCCESS;
1431    }
```

6.4.5 Response Session Processing

6.4.5.1 Introduction

The following functions build the session area in a response and handle the audit sessions (if present).

6.4.5.2 ComputeRpHash()

Function to compute *rpHash* (Response Parameter Hash). The *rpHash* is only computed if there is an HMAC authorization session and the return code is TPM_RC_SUCCESS.

```
1432    static TPM2B_DIGEST *
1433    ComputeRpHash(
1434        COMMAND          *command,       // IN: command structure
1435        TPM_ALG_ID        hashAlg        // IN: hash algorithm to compute rpHash
1436        )
1437    {
1438        TPM2B_DIGEST     *rpHash = GetRpHashPointer(command, hashAlg);
1439        HASH_STATE        hashState;
1440    //
1441        if(rpHash->t.size == 0)
1442        {
1443        //   rpHash := hash(responseCode || commandCode || parameters)
1444
1445        // Initiate hash creation.
1446            rpHash->t.size = CryptHashStart(&hashState, hashAlg);
1447
1448            // Add hash constituents.
1449            CryptDigestUpdateInt(&hashState, sizeof(TPM_RC), TPM_RC_SUCCESS);
1450            CryptDigestUpdateInt(&hashState, sizeof(TPM_CC), command->code);
1451            CryptDigestUpdate(&hashState, command->parameterSize,
1452                              command->parameterBuffer);
1453            // Complete hash computation.
1454            CryptHashEnd2B(&hashState, &rpHash->b);
1455        }
1456        return rpHash;
1457    }
```

6.4.5.3 InitAuditSession()

This function initializes the audit data in an audit session.

```
1458    static void
1459    InitAuditSession(
1460        SESSION          *session        // session to be initialized
1461        )
1462    {
1463        // Mark session as an audit session.
1464        session->attributes.isAudit = SET;
1465
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
1466        // Audit session can not be bound.
1467        session->attributes.isBound = CLEAR;
1468
1469        // Size of the audit log is the size of session hash algorithm digest.
1470        session->u2.auditDigest.t.size = CryptHashGetDigestSize(session->authHashAlg);
1471
1472        // Set the original digest value to be 0.
1473        MemorySet(&session->u2.auditDigest.t.buffer,
1474                  0,
1475                  session->u2.auditDigest.t.size);
1476        return;
1477    }
```

6.4.5.4 UpdateAuditDigest

Function to update an audit digest

```
1478    static void
1479    UpdateAuditDigest(
1480        COMMAND          *command,
1481        TPMI_ALG_HASH     hashAlg,
1482        TPM2B_DIGEST     *digest
1483        )
1484    {
1485        HASH_STATE        hashState;
1486        TPM2B_DIGEST     *cpHash = GetCpHash(command, hashAlg);
1487        TPM2B_DIGEST     *rpHash = ComputeRpHash(command, hashAlg);
1488    //
1489        pAssert(cpHash != NULL);
1490
1491        // digestNew :=  hash (digestOld || cpHash || rpHash)
1492            // Start hash computation.
1493        digest->t.size = CryptHashStart(&hashState, hashAlg);
1494            // Add old digest.
1495        CryptDigestUpdate2B(&hashState, &digest->b);
1496            // Add cpHash
1497        CryptDigestUpdate2B(&hashState, &cpHash->b);
1498            // Add rpHash
1499        CryptDigestUpdate2B(&hashState, &rpHash->b);
1500            // Finalize the hash.
1501        CryptHashEnd2B(&hashState, &digest->b);
1502    }
```

6.4.5.5 Audit()

This function updates the audit digest in an audit session.

```
1503    static void
1504    Audit(
1505        COMMAND          *command,       // IN: primary control structure
1506        SESSION          *auditSession   // IN: loaded audit session
1507        )
1508    {
1509        UpdateAuditDigest(command, auditSession->authHashAlg,
1510                          &auditSession->u2.auditDigest);
1511        return;
1512    }
1513    #ifdef  TPM_CC_GetCommandAuditDigest
```

6.4.5.6 CommandAudit()

This function updates the command audit digest.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
1514 static void
1515 CommandAudit(
1516     COMMAND           *command         // IN:
1517     )
1518 {
1519     // If the digest.size is one, it indicates the special case of changing
1520     // the audit hash algorithm. For this case, no audit is done on exit.
1521     // NOTE: When the hash algorithm is changed, g_updateNV is set in order to
1522     // force an update to the NV on exit so that the change in digest will
1523     // be recorded. So, it is safe to exit here without setting any flags
1524     // because the digest change will be written to NV when this code exits.
1525     if(gr.commandAuditDigest.t.size == 1)
1526     {
1527         gr.commandAuditDigest.t.size = 0;
1528         return;
1529     }
1530     // If the digest size is zero, need to start a new digest and increment
1531     // the audit counter.
1532     if(gr.commandAuditDigest.t.size == 0)
1533     {
1534         gr.commandAuditDigest.t.size = CryptHashGetDigestSize(gp.auditHashAlg);
1535         MemorySet(gr.commandAuditDigest.t.buffer,
1536                   0,
1537                   gr.commandAuditDigest.t.size);
1538
1539         // Bump the counter and save its value to NV.
1540         gp.auditCounter++;
1541         NV_SYNC_PERSISTENT(auditCounter);
1542     }
1543     UpdateAuditDigest(command, gp.auditHashAlg, &gr.commandAuditDigest);
1544     return;
1545 }
1546 #endif
```

6.4.5.7 UpdateAuditSessionStatus()

Function to update the internal audit related states of a session. It

a) initializes the session as audit session and sets it to be exclusive if this is the first time it is used for audit or audit reset was requested;

b) reports exclusive audit session;

c) extends audit log; and

d) clears exclusive audit session if no audit session found in the command.

```
1547 static void
1548 UpdateAuditSessionStatus(
1549     COMMAND           *command         // IN: primary control structure
1550     )
1551 {
1552     UINT32             i;
1553     TPM_HANDLE         auditSession = TPM_RH_UNASSIGNED;
1554 //
1555     // Iterate through sessions
1556     for(i = 0; i < command->sessionNum; i++)
1557     {
1558         SESSION      *session;
1559 //
1560         // PW session do not have a loaded session and can not be an audit
1561         // session either.  Skip it.
1562         if(s_sessionHandles[i] == TPM_RS_PW)
1563             continue;
1564         session = SessionGet(s_sessionHandles[i]);
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
1565
1566            // If a session is used for audit
1567            if(IS_ATTRIBUTE(s_attributes[i], TPMA_SESSION, audit))
1568            {
1569                // An audit session has been found
1570                auditSession = s_sessionHandles[i];
1571
1572                // If the session has not been an audit session yet, or
1573                // the auditSetting bits indicate a reset, initialize it and set
1574                // it to be the exclusive session
1575                if(session->attributes.isAudit == CLEAR
1576                   || IS_ATTRIBUTE(s_attributes[i], TPMA_SESSION, auditReset))
1577                {
1578                    InitAuditSession(session);
1579                    g_exclusiveAuditSession = auditSession;
1580                }
1581                else
1582                {
1583                    // Check if the audit session is the current exclusive audit
1584                    // session and, if not, clear previous exclusive audit session.
1585                    if(g_exclusiveAuditSession != auditSession)
1586                        g_exclusiveAuditSession = TPM_RH_UNASSIGNED;
1587                }
1588                // Report audit session exclusivity.
1589                if(g_exclusiveAuditSession == auditSession)
1590                {
1591                    SET_ATTRIBUTE(s_attributes[i], TPMA_SESSION, auditExclusive);
1592                }
1593                else
1594                {
1595                    CLEAR_ATTRIBUTE(s_attributes[i], TPMA_SESSION, auditExclusive);
1596                }
1597                // Extend audit log.
1598                Audit(command, session);
1599            }
1600        }
1601        // If no audit session is found in the command, and the command allows
1602        // a session then, clear the current exclusive
1603        // audit session.
1604        if(auditSession == TPM_RH_UNASSIGNED && IsSessionAllowed(command->index))
1605        {
1606            g_exclusiveAuditSession = TPM_RH_UNASSIGNED;
1607        }
1608        return;
1609    }
```

6.4.5.8 ComputeResponseHMAC()

Function to compute HMAC for authorization session in a response.

```
1610    static void
1611    ComputeResponseHMAC(
1612        COMMAND         *command,         // IN: command structure
1613        UINT32           sessionIndex,    // IN: session index to be processed
1614        SESSION         *session,         // IN: loaded session
1615        TPM2B_DIGEST    *hmac             // OUT: authHMAC
1616        )
1617    {
1618        TPM2B_TYPE(KEY, (sizeof(AUTH_VALUE) * 2));
1619        TPM2B_KEY        key;       // HMAC key
1620        BYTE             marshalBuffer[sizeof(TPMA_SESSION)];
1621        BYTE            *buffer;
1622        UINT32           marshalSize;
1623        HMAC_STATE       hmacState;
```

```
1624        TPM2B_DIGEST    *rpHash = ComputeRpHash(command, session->authHashAlg);
1625    //
1626        // Generate HMAC key
1627        MemoryCopy2B(&key.b, &session->sessionKey.b, sizeof(key.t.buffer));
1628
1629        // Add the object authValue if required
1630        if(session->attributes.includeAuth == SET)
1631        {
1632            // Note: includeAuth may be SET for a policy that is used in
1633            // UndefineSpaceSpecial(). At this point, the Index has been deleted
1634            // so the includeAuth will have no meaning. However, the
1635            // s_associatedHandles[] value for the session is now set to TPM_RH_NULL so
1636            // this will return the authValue associated with TPM_RH_NULL and that is
1637            // and empty buffer.
1638            TPM2B_AUTH          authValue;
1639    //
1640            // Get the authValue with trailing zeros removed
1641            EntityGetAuthValue(s_associatedHandles[sessionIndex], &authValue);
1642
1643            // Add it to the key
1644            MemoryConcat2B(&key.b, &authValue.b, sizeof(key.t.buffer));
1645        }
1646
1647        // if the HMAC key size is 0, the response HMAC is computed according to the
1648        // input HMAC
1649        if(key.t.size == 0
1650           && s_inputAuthValues[sessionIndex].t.size == 0)
1651        {
1652            hmac->t.size = 0;
1653            return;
1654        }
1655        // Start HMAC computation.
1656        hmac->t.size = CryptHmacStart2B(&hmacState, session->authHashAlg, &key.b);
1657
1658        // Add hash components.
1659        CryptDigestUpdate2B(&hmacState.hashState, &rpHash->b);
1660        CryptDigestUpdate2B(&hmacState.hashState, &session->nonceTPM.b);
1661        CryptDigestUpdate2B(&hmacState.hashState, &s_nonceCaller[sessionIndex].b);
1662
1663        // Add session attributes.
1664        buffer = marshalBuffer;
1665        marshalSize = TPMA_SESSION_Marshal(&s_attributes[sessionIndex], &buffer, NULL);
1666        CryptDigestUpdate(&hmacState.hashState, marshalSize, marshalBuffer);
1667
1668        // Finalize HMAC.
1669        CryptHmacEnd2B(&hmacState, &hmac->b);
1670
1671        return;
1672    }
```

6.4.5.9 UpdateInternalSession()

Updates internal sessions:

a) Restarts session time.

b) Clears a policy session since nonce is rolling.

```
1673    static void
1674    UpdateInternalSession(
1675        SESSION         *session,       // IN: the session structure
1676        UINT32           i              // IN: session number
1677        )
1678    {
1679        // If nonce is rolling in a policy session, the policy related data
```

 Copyright © TCG 2006-2020

```
1680        // will be re-initialized.
1681        if(HandleGetType(s_sessionHandles[i]) == TPM_HT_POLICY_SESSION
1682           && IS_ATTRIBUTE(s_attributes[i], TPMA_SESSION, continueSession))
1683        {
1684            // When the nonce rolls it starts a new timing interval for the
1685            // policy session.
1686            SessionResetPolicyData(session);
1687            SessionSetStartTime(session);
1688        }
1689        return;
1690    }
```

6.4.5.10 BuildSingleResponseAuth()

Function to compute response HMAC value for a policy or HMAC session.

```
1691    static TPM2B_NONCE *
1692    BuildSingleResponseAuth(
1693        COMMAND          *command,         // IN: command structure
1694        UINT32            sessionIndex,    // IN: session index to be processed
1695        TPM2B_AUTH       *auth             // OUT: authHMAC
1696        )
1697    {
1698        // Fill in policy/HMAC based session response.
1699        SESSION     *session = SessionGet(s_sessionHandles[sessionIndex]);
1700    //
1701        // If the session is a policy session with isPasswordNeeded SET, the
1702        // authorization field is empty.
1703        if(HandleGetType(s_sessionHandles[sessionIndex]) == TPM_HT_POLICY_SESSION
1704           && session->attributes.isPasswordNeeded == SET)
1705            auth->t.size = 0;
1706        else
1707            // Compute response HMAC.
1708            ComputeResponseHMAC(command, sessionIndex, session, auth);
1709
1710        UpdateInternalSession(session, sessionIndex);
1711        return &session->nonceTPM;
1712    }
```

6.4.5.11 UpdateAllNonceTPM()

Updates TPM nonce for all sessions in command.

```
1713    static void
1714    UpdateAllNonceTPM(
1715        COMMAND          *command         // IN: controlling structure
1716        )
1717    {
1718        UINT32      i;
1719        SESSION     *session;
1720    //
1721        for(i = 0; i < command->sessionNum; i++)
1722        {
1723            // If not a PW session, compute the new nonceTPM.
1724            if(s_sessionHandles[i] != TPM_RS_PW)
1725            {
1726                session = SessionGet(s_sessionHandles[i]);
1727                // Update nonceTPM in both internal session and response.
1728                CryptRandomGenerate(session->nonceTPM.t.size,
1729                                    session->nonceTPM.t.buffer);
1730            }
1731        }
1732        return;
```

```
1733 }
```

6.4.5.12 BuildResponseSession()

Function to build Session buffer in a response. The authorization data is added to the end of command->*responseBuffer*. The size of the authorization area is accumulated in command->*authSize*. When this is called, command->*responseBuffer* is pointing at the next location in the response buffer to be filled. This is where the authorization sessions will go, if any. command->*parameterSize* is the number of bytes that have been marshaled as parameters in the output buffer.

```
1734 void
1735 BuildResponseSession(
1736     COMMAND         *command        // IN: structure that has relevant command
1737                                     //     information
1738     )
1739 {
1740     pAssert(command->authSize == 0);
1741
1742     // Reset the parameter buffer to point to the start of the parameters so that
1743     // there is a starting point for any rpHash that might be generated and so there
1744     // is a place where parameter encryption would start
1745     command->parameterBuffer = command->responseBuffer - command->parameterSize;
1746
1747     // Session nonces should be updated before parameter encryption
1748     if(command->tag == TPM_ST_SESSIONS)
1749     {
1750         UpdateAllNonceTPM(command);
1751
1752         // Encrypt first parameter if applicable. Parameter encryption should
1753         // happen after nonce update and before any rpHash is computed.
1754         // If the encrypt session is associated with a handle, the authValue of
1755         // this handle will be concatenated with sessionKey to generate
1756         // encryption key, no matter if the handle is the session bound entity
1757         // or not. The authValue is added to sessionKey only when the authValue
1758         // is available.
1759         if(s_encryptSessionIndex != UNDEFINED_INDEX)
1760         {
1761             UINT32          size;

7 Command Support Functions

7.1 Introduction

This clause contains support routines that are called by the command action code in TPM 2.0 Part 3. The functions are grouped by the command group that is supported by the functions.

7.2 Attestation Command Support (Attest_spt.c)

7.2.1 Includes

```
1  #include "Tpm.h"
2  #include "Attest_spt_fp.h"
```

7.2.2 Functions

7.2.2.1 FillInAttestInfo()

Fill in common fields of TPMS_ATTEST structure.

```
3  void
4  FillInAttestInfo(
5      TPMI_DH_OBJECT       signHandle,     // IN: handle of signing object
6      TPMT_SIG_SCHEME     *scheme,         // IN/OUT: scheme to be used for signing
7      TPM2B_DATA          *data,           // IN: qualifying data
8      TPMS_ATTEST         *attest          // OUT: attest structure
9      )
10 {
11     OBJECT              *signObject = HandleToObject(signHandle);
12
13         // Magic number
14     attest->magic = TPM_GENERATED_VALUE;
15
16     if(signObject == NULL)
17     {
18         // The name for a null handle is TPM_RH_NULL
19         // This is defined because UINT32_TO_BYTE_ARRAY does a cast. If the
20         // size of the cast is smaller than a constant, the compiler warns
21         // about the truncation of a constant value.
22         TPM_HANDLE      nullHandle = TPM_RH_NULL;
23         attest->qualifiedSigner.t.size = sizeof(TPM_HANDLE);
24         UINT32_TO_BYTE_ARRAY(nullHandle, attest->qualifiedSigner.t.name);
25     }
26     else
27     {
28         // Certifying object qualified name
29         // if the scheme is anonymous, this is an empty buffer
30         if(CryptIsSchemeAnonymous(scheme->scheme))
31             attest->qualifiedSigner.t.size = 0;
32         else
33             attest->qualifiedSigner = signObject->qualifiedName;
34     }
35     // current clock in plain text
36     TimeFillInfo(&attest->clockInfo);
37
38     // Firmware version in plain text
39     attest->firmwareVersion = ((UINT64)gp.firmwareV1 << (sizeof(UINT32) * 8));
40     attest->firmwareVersion += gp.firmwareV2;
41
```

```
42      // Check the hierarchy of sign object.  For NULL sign handle, the hierarchy
43      // will be TPM_RH_NULL
44      if((signObject == NULL)
45         || (!signObject->attributes.epsHierarchy
46             && !signObject->attributes.ppsHierarchy))
47      {
48          // For signing key that is not in platform or endorsement hierarchy,
49          // obfuscate the reset, restart and firmware version information
50          UINT64          obfuscation[2];
51          CryptKDFa(CONTEXT_INTEGRITY_HASH_ALG, &gp.shProof.b, OBFUSCATE_STRING,
52                    &attest->qualifiedSigner.b, NULL, 128,
53                    (BYTE *)&obfuscation[0], NULL, FALSE);
54          // Obfuscate data
55          attest->firmwareVersion += obfuscation[0];
56          attest->clockInfo.resetCount += (UINT32)(obfuscation[1] >> 32);
57          attest->clockInfo.restartCount += (UINT32)obfuscation[1];
58      }
59      // External data
60      if(CryptIsSchemeAnonymous(scheme->scheme))
61          attest->extraData.t.size = 0;
62      else
63      {
64          // If we move the data to the attestation structure, then it is not
65          // used in the signing operation except as part of the signed data
66          attest->extraData = *data;
67          data->t.size = 0;
68      }
69  }
```

7.2.2.2 SignAttestInfo()

Sign a TPMS_ATTEST structure. If *signHandle* is TPM_RH_NULL, a null signature is returned.

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*signHandle* references not a signing key
TPM_RC_SCHEME	*scheme* is not compatible with *signHandle* type
TPM_RC_VALUE	digest generated for the given *scheme* is greater than the modulus of *signHandle* (for an RSA key); invalid commit status or failed to generate r value (for an ECC key)

```
70  TPM_RC
71  SignAttestInfo(
72      OBJECT              *signKey,           // IN: sign object
73      TPMT_SIG_SCHEME     *scheme,            // IN: sign scheme
74      TPMS_ATTEST         *certifyInfo,       // IN: the data to be signed
75      TPM2B_DATA          *qualifyingData,    // IN: extra data for the signing
76                                              //     process
77      TPM2B_ATTEST        *attest,            // OUT: marshaled attest blob to be
78                                              //     signed
79      TPMT_SIGNATURE      *signature          // OUT: signature
80      )
81  {
82      BYTE                    *buffer;
83      HASH_STATE              hashState;
84      TPM2B_DIGEST            digest;
85      TPM_RC                  result;
86
87      // Marshal TPMS_ATTEST structure for hash
88      buffer = attest->t.attestationData;
89      attest->t.size = TPMS_ATTEST_Marshal(certifyInfo, &buffer, NULL);
90
91      if(signKey == NULL)
```

```
 92         {
 93             signature->sigAlg = TPM_ALG_NULL;
 94             result = TPM_RC_SUCCESS;
 95         }
 96         else
 97         {
 98             TPMI_ALG_HASH           hashAlg;
 99             // Compute hash
100             hashAlg = scheme->details.any.hashAlg;
101             // need to set the receive buffer to get something put in it
102             digest.t.size = sizeof(digest.t.buffer);
103             digest.t.size = CryptHashBlock(hashAlg, attest->t.size,
104                                            attest->t.attestationData,
105                                            digest.t.size, digest.t.buffer);
106             // If there is qualifying data, need to rehash the data
107             // hash(qualifyingData || hash(attestationData))
108             if(qualifyingData->t.size != 0)
109             {
110                 CryptHashStart(&hashState, hashAlg);
111                 CryptDigestUpdate2B(&hashState, &qualifyingData->b);
112                 CryptDigestUpdate2B(&hashState, &digest.b);
113                 CryptHashEnd2B(&hashState, &digest.b);
114             }
115             // Sign the hash. A TPM_RC_VALUE, TPM_RC_SCHEME, or
116             // TPM_RC_ATTRIBUTES error may be returned at this point
117             result = CryptSign(signKey, scheme, &digest, signature);
118
119             // Since the clock is used in an attestation, the state in NV is no longer
120             // "orderly" with respect to the data in RAM if the signature is valid
121             if(result == TPM_RC_SUCCESS)
122             {
123                 // Command uses the clock so need to clear the orderly state if it is
124                 // set.
125                 result = NvClearOrderly();
126             }
127         }
128         return result;
129     }
```

7.2.2.3 IsSigningObject()

Checks to see if the object is OK for signing. This is here rather than in Object_spt.c because all the attestation commands use this file but not Object_spt.c.

Return Value	Meaning
TRUE(1)	object may sign
FALSE(0)	object may not sign

```
130     BOOL
131     IsSigningObject(
132         OBJECT          *object         // IN:
133         )
134     {
135         return ((object == NULL)
136                 || ((IS_ATTRIBUTE(object->publicArea.objectAttributes, TPMA_OBJECT, sign)
137                    && object->publicArea.type != TPM_ALG_SYMCIPHER)));
138     }
```

7.3 Context Management Command Support (Context_spt.c)

7.3.1 Includes

```
1  #include "Tpm.h"
2  #include "Context_spt_fp.h"
```

7.3.2 Functions

7.3.2.1 ComputeContextProtectionKey()

This function retrieves the symmetric protection key for context encryption It is used by TPM2_ConextSave() and TPM2_ContextLoad() to create the symmetric encryption key and iv

```
3  void
4  ComputeContextProtectionKey(
5      TPMS_CONTEXT     *contextBlob,    // IN: context blob
6      TPM2B_SYM_KEY    *symKey,         // OUT: the symmetric key
7      TPM2B_IV         *iv              // OUT: the IV.
8      )
9  {
10     UINT16            symKeyBits;     // number of bits in the parent's
11                                       //   symmetric key
12     TPM2B_PROOF      *proof = NULL;   // the proof value to use. Is null for
13                                       //   everything but a primary object in
14                                       //   the Endorsement Hierarchy
15
16     BYTE              kdfResult[sizeof(TPMU_HA) * 2];// Value produced by the KDF
17
18     TPM2B_DATA        sequence2B, handle2B;
19
20     // Get proof value
21     proof = HierarchyGetProof(contextBlob->hierarchy);
22
23     // Get sequence value in 2B format
24     sequence2B.t.size = sizeof(contextBlob->sequence);
25     cAssert(sizeof(contextBlob->sequence) <= sizeof(sequence2B.t.buffer));
26     MemoryCopy(sequence2B.t.buffer, &contextBlob->sequence,
27                sizeof(contextBlob->sequence));
28
29     // Get handle value in 2B format
30     handle2B.t.size = sizeof(contextBlob->savedHandle);
31     cAssert(sizeof(contextBlob->savedHandle) <= sizeof(handle2B.t.buffer));
32     MemoryCopy(handle2B.t.buffer, &contextBlob->savedHandle,
33                sizeof(contextBlob->savedHandle));
34
35     // Get the symmetric encryption key size
36     symKey->t.size = CONTEXT_ENCRYPT_KEY_BYTES;
37     symKeyBits = CONTEXT_ENCRYPT_KEY_BITS;
38     // Get the size of the IV for the algorithm
39     iv->t.size = CryptGetSymmetricBlockSize(CONTEXT_ENCRYPT_ALG, symKeyBits);
40

53
54      return;
55  }
```

7.3.2.2 ComputeContextIntegrity()

Generate the integrity hash for a context It is used by TPM2_ContextSave() to create an integrity hash and by TPM2_ContextLoad() to compare an integrity hash

```
56  void
57  ComputeContextIntegrity(
58      TPMS_CONTEXT    *contextBlob,    // IN: context blob
59      TPM2B_DIGEST    *integrity       // OUT: integrity
60      )
61  {
62      HMAC_STATE          hmacState;
63      TPM2B_PROOF        *proof;
64      UINT16              integritySize;
65
66      // Get proof value
67      proof = HierarchyGetProof(contextBlob->hierarchy);
68
69      // Start HMAC
70      integrity->t.size = CryptHmacStart2B(&hmacState, CONTEXT_INTEGRITY_HASH_ALG,
71                                           &proof->b);
72
73      // Compute integrity size at the beginning of context blob
74      integritySize = sizeof(integrity->t.size) + integrity->t.size;
75
76      // Adding total reset counter so that the context cannot be
77      // used after a TPM Reset
78      CryptDigestUpdateInt(&hmacState.hashState, sizeof(gp.totalResetCount),
79                           gp.totalResetCount);
80
81      // If this is a ST_CLEAR object, add the clear count
82      // so that this contest cannot be loaded after a TPM Restart
83      if(contextBlob->savedHandle == 0x80000002)
84          CryptDigestUpdateInt(&hmacState.hashState, sizeof(gr.clearCount),
85                               gr.clearCount);
86
87      // Adding sequence number to the HMAC to make sure that it doesn't
88      // get changed
89      CryptDigestUpdateInt(&hmacState.hashState, sizeof(contextBlob->sequence),
90                           contextBlob->sequence);
91
92      // Protect the handle
93      CryptDigestUpdateInt(&hmacState.hashState, sizeof(contextBlob->savedHandle),
94                           contextBlob->savedHandle);
95
96      // Adding sensitive contextData, skip the leading integrity area
97      CryptDigestUpdate(&hmacState.hashState,
98                        contextBlob->contextBlob.t.size - integritySize,
99                        contextBlob->contextBlob.t.buffer + integritySize);
100
101     // Complete HMAC
102     CryptHmacEnd2B(&hmacState, &integrity->b);
103
104     return;
105 }
```

7.3.2.3 SequenceDataExport()

This function is used scan through the sequence object and either modify the hash state data for export (*contextSave*) or to import it into the internal format (*contextLoad*). This function should only be called after the sequence object has been copied to the context buffer (*contextSave*) or from the context buffer into the sequence object. The presumption is that the context buffer version of the data is the same size as the internal representation so nothing outsize of the hash context area gets modified.

```
106  void
107  SequenceDataExport(
108      HASH_OBJECT          *object,         // IN: an internal hash object
109      HASH_OBJECT_BUFFER   *exportObject    // OUT: a sequence context in a buffer
110      )
111  {
112      // If the hash object is not an event, then only one hash context is needed
113      int                   count = (object->attributes.eventSeq) ? HASH_COUNT : 1;
114
115      for(count--; count >= 0; count--)
116      {
117          HASH_STATE          *hash = &object->state.hashState[count];
118          size_t               offset = (BYTE *)hash - (BYTE *)object;
119          BYTE                *exportHash = &((BYTE *)exportObject)[offset];
120
121          CryptHashExportState(hash, (EXPORT_HASH_STATE *)exportHash);
122      }
123  }
```

7.3.2.4 SequenceDataImport()

This function is used scan through the sequence object and either modify the hash state data for export (*contextSave*) or to import it into the internal format (*contextLoad*). This function should only be called after the sequence object has been copied to the context buffer (*contextSave*) or from the context buffer into the sequence object. The presumption is that the context buffer version of the data is the same size as the internal representation so nothing outsize of the hash context area gets modified.

```
124  void
125  SequenceDataImport(
126      HASH_OBJECT          *object,         // IN/OUT: an internal hash object
127      HASH_OBJECT_BUFFER   *exportObject    // IN/OUT: a sequence context in a buffer
128      )
129  {
130      // If the hash object is not an event, then only one hash context is needed
131      int                   count = (object->attributes.eventSeq) ? HASH_COUNT : 1;
132
133      for(count--; count >= 0; count--)
134      {
135          HASH_STATE          *hash = &object->state.hashState[count];
136          size_t               offset = (BYTE *)hash - (BYTE *)object;
137          BYTE                *importHash = &((BYTE *)exportObject)[offset];
138  //
139          CryptHashImportState(hash, (EXPORT_HASH_STATE *)importHash);
140      }
141  }
```

3  #include "PolicySigned_fp.h"
4  #include "PolicySecret_fp.h"
5  #include "PolicyTicket_fp.h"
```

7.4.2 Functions

7.4.2.1 PolicyParameterChecks()

This function validates the common parameters of TPM2_PolicySiged() and TPM2_PolicySecret(). The common parameters are *nonceTPM*, *expiration*, and *cpHashA*.

```
6  TPM_RC
7  PolicyParameterChecks(
8      SESSION          *session,
9      UINT64            authTimeout,
10     TPM2B_DIGEST     *cpHashA,
11     TPM2B_NONCE      *nonce,
12     TPM_RC            blameNonce,
13     TPM_RC            blameCpHash,
14     TPM_RC            blameExpiration
15     )
16 {
17     // Validate that input nonceTPM is correct if present
18     if(nonce != NULL && nonce->t.size != 0)
19     {
20         if(!MemoryEqual2B(&nonce->b, &session->nonceTPM.b))
21             return TPM_RCS_NONCE + blameNonce;
22     }
23     // If authTimeout is set (expiration != 0...
24     if(authTimeout != 0)
25     {
26         // Validate input expiration.
27         // Cannot compare time if clock stop advancing.  A TPM_RC_NV_UNAVAILABLE
28         // or TPM_RC_NV_RATE error may be returned here.
29         RETURN_IF_NV_IS_NOT_AVAILABLE;
30
31         // if the time has already passed or the time epoch has changed then the
32         // time value is no longer good.
33         if((authTimeout < g_time)
34            || (session->epoch != g_timeEpoch))
35             return TPM_RCS_EXPIRED + blameExpiration;
36     }
37     // If the cpHash is present, then check it
38     if(cpHashA != NULL && cpHashA->t.size != 0)
39     {
40         // The cpHash input has to have the correct size
41         if(cpHashA->t.size != session->u2.policyDigest.t.size)
42             return TPM_RCS_SIZE + blameCpHash;
43
44         // If the cpHash has already been set, then this input value
45         // must match the current value.
46         if(session->u1.cpHash.b.size != 0
47            && !MemoryEqual2B(&cpHashA->b, &session->u1.cpHash.b))
48             return TPM_RC_CPHASH;
49     }
```

```
50      return TPM_RC_SUCCESS;
51  }
```

7.4.2.2 PolicyContextUpdate()

Update policy hash Update the *policyDigest* in policy session by extending *policyRef* and *objectName* to it. This will also update the *cpHash* if it is present.

```
52  void
53  PolicyContextUpdate(
54      TPM_CC           commandCode,   // IN: command code
55      TPM2B_NAME      *name,          // IN: name of entity
56      TPM2B_NONCE     *ref,           // IN: the reference data
57      TPM2B_DIGEST    *cpHash,        // IN: the cpHash (optional)
58      UINT64           policyTimeout, // IN: the timeout value for the policy
59      SESSION         *session        // IN/OUT: policy session to be updated
60      )
61  {
62      HASH_STATE           hashState;
63
64      // Start hash
65     CryptHashStart(&hashState, session->authHashAlg);
66
67      // policyDigest size should always be the digest size of session hash algorithm.
68      pAssert(session->u2.policyDigest.t.size
69              == CryptHashGetDigestSize(session->authHashAlg));
70
71      // add old digest
72      CryptDigestUpdate2B(&hashState, &session->u2.policyDigest.b);
73
74      // add commandCode
75      CryptDigestUpdateInt(&hashState, sizeof(commandCode), commandCode);
76
77      // add name if applicable
78      if(name != NULL)
79          CryptDigestUpdate2B(&hashState, &name->b);
80
81      // Complete the digest and get the results
82      CryptHashEnd2B(&hashState, &session->u2.policyDigest.b);
83
84      // If the policy reference is not null, do a second update to the digest.
85      if(ref != NULL)
86      {
87
88          // Start second hash computation
89          CryptHashStart(&hashState, session->authHashAlg);
90
91          // add policyDigest
92          CryptDigestUpdate2B(&hashState, &session->u2.policyDigest.b);
93
94          // add policyRef
95          CryptDigestUpdate2B(&hashState, &ref->b);
96
97          // Complete second digest
98          CryptHashEnd2B(&hashState, &session->u2.policyDigest.b);
99      }
100     // Deal with the cpHash. If the cpHash value is present
101     // then it would have already been checked to make sure that
102     // it is compatible with the current value so all we need
103     // to do here is copy it and set the isCpHashDefined attribute
104     if(cpHash != NULL && cpHash->t.size != 0)
105     {
106         session->u1.cpHash = *cpHash;
107         session->attributes.isCpHashDefined = SET;
```

 Copyright © TCG 2006-2020

```
108     }
109
110     // update the timeout if it is specified
111     if(policyTimeout != 0)
112     {
113         // If the timeout has not been set, then set it to the new value
114         // than the current timeout then set it to the new value
115         if(session->timeout == 0 || session->timeout > policyTimeout)
116             session->timeout = policyTimeout;
117     }
118     return;
119 }
```

7.4.2.3 ComputeAuthTimeout()

This function is used to determine what the authorization timeout value for the session should be.

```
120 UINT64
121 ComputeAuthTimeout(
122     SESSION         *session,               // IN: the session containing the time
123                                             //     values
124     INT32            expiration,            // IN: either the number of seconds from
125                                             //     the start of the session or the
126                                             //     time in g_timer;
127     TPM2B_NONCE     *nonce                  // IN: indicator of the time base
128     )
129 {
130     UINT64           policyTime;
131     // If no expiration, policy time is 0
132     if(expiration == 0)
133         policyTime = 0;
134     else
135     {
136         if(expiration < 0)
137             expiration = -expiration;
138         if(nonce->t.size == 0)
139             // The input time is absolute Time (not Clock), but it is expressed
140             // in seconds. To make sure that we don't time out too early, take the
141             // current value of milliseconds in g_time and add that to the input
142             // seconds value.
143             policyTime = (((UINT64)expiration) * 1000) + g_time % 1000;
144         else
145             // The policy timeout is the absolute value of the expiration in seconds
146             // added to the start time of the policy.
147             policyTime = session->startTime + (((UINT64)expiration) * 1000);
148
149     }
150     return policyTime;
151 }
```

7.4.2.4 PolicyDigestClear()

Function to reset the *policyDigest* of a session

```
152 void
153 PolicyDigestClear(
154     SESSION         *session
155     )
156 {
157     session->u2.policyDigest.t.size = CryptHashGetDigestSize(session->authHashAlg);
158     MemorySet(session->u2.policyDigest.t.buffer, 0,
159               session->u2.policyDigest.t.size);
160 }
```

```

230             default:
231                 FAIL(FATAL_ERROR_INTERNAL);
232                 break;
233         }
234         return TRUE;
235 }
```

7.5 NV Command Support (NV_spt.c)

7.5.1 Includes

```
1   #include "Tpm.h"
2   #include "NV_spt_fp.h"
```

7.5.2 Functions

7.5.2.1 NvReadAccessChecks()

Common routine for validating a read Used by TPM2_NV_Read(), TPM2_NV_ReadLock() and TPM2_PolicyNV()

Error Returns	Meaning
TPM_RC_NV_AUTHORIZATION	*autHandle* is not allowed to authorize read of the index
TPM_RC_NV_LOCKED	Read locked
TPM_RC_NV_UNINITIALIZED	Try to read an uninitialized index

```
3   TPM_RC
4   NvReadAccessChecks(
5       TPM_HANDLE       authHandle,    // IN: the handle that provided the
6                                       //     authorization
7       TPM_HANDLE       nvHandle,      // IN: the handle of the NV index to be read
8       TPMA_NV          attributes     // IN: the attributes of 'nvHandle'
9       )
10  {
11      // If data is read locked, returns an error
12     if(IS_ATTRIBUTE(attributes, TPMA_NV, READLOCKED))
13         return TPM_RC_NV_LOCKED;
14      // If the authorization was provided by the owner or platform, then check
15      // that the attributes allow the read.  If the authorization handle
16      // is the same as the index, then the checks were made when the authorization
17      // was checked..
18      if(authHandle == TPM_RH_OWNER)
19      {
20          // If Owner provided authorization then ONWERWRITE must be SET
21          if(!IS_ATTRIBUTE(attributes, TPMA_NV, OWNERREAD))
22              return TPM_RC_NV_AUTHORIZATION;
23      }
24      else if(authHandle == TPM_RH_PLATFORM)
25      {
26          // If Platform provided authorization then PPWRITE must be SET
27          if(!IS_ATTRIBUTE(attributes, TPMA_NV, PPREAD))
28              return TPM_RC_NV_AUTHORIZATION;
29      }
30      // If neither Owner nor Platform provided authorization, make sure that it was
31      // provided by this index.
32      else if(authHandle != nvHandle)
33          return TPM_RC_NV_AUTHORIZATION;
34
35  // If the index has not been written, then the value cannot be read
36  // NOTE: This has to come after other access checks to make sure that
37  // the proper authorization is given to TPM2_NV_ReadLock()
38      if(!IS_ATTRIBUTE(attributes, TPMA_NV, WRITTEN))
39          return TPM_RC_NV_UNINITIALIZED;
40
41      return TPM_RC_SUCCESS;
42  }
```

7.5.2.2 NvWriteAccessChecks()

Common routine for validating a write Used by TPM2_NV_Write(), TPM2_NV_Increment(), TPM2_SetBits(), and TPM2_NV_WriteLock()

Error Returns	Meaning
TPM_RC_NV_AUTHORIZATION	Authorization fails
TPM_RC_NV_LOCKED	Write locked

```
43  TPM_RC
44  NvWriteAccessChecks(
45      TPM_HANDLE       authHandle,    // IN: the handle that provided the
46                                      //     authorization
47      TPM_HANDLE       nvHandle,      // IN: the handle of the NV index to be written
48      TPMA_NV          attributes     // IN: the attributes of 'nvHandle'
49      )
50  {
51      // If data is write locked, returns an error
52      if(IS_ATTRIBUTE(attributes, TPMA_NV, WRITELOCKED))
53          return TPM_RC_NV_LOCKED;
54          // If the authorization was provided by the owner or platform, then check
55      // that the attributes allow the write.  If the authorization handle
56      // is the same as the index, then the checks were made when the authorization
57      // was checked..
58      if(authHandle == TPM_RH_OWNER)
59      {
60          // If Owner provided authorization then ONWERWRITE must be SET
61          if(!IS_ATTRIBUTE(attributes, TPMA_NV, OWNERWRITE))
62              return TPM_RC_NV_AUTHORIZATION;
63      }
64      else if(authHandle == TPM_RH_PLATFORM)
65      {
66          // If Platform provided authorization then PPWRITE must be SET
67          if(!IS_ATTRIBUTE(attributes, TPMA_NV, PPWRITE))
68              return TPM_RC_NV_AUTHORIZATION;
69      }
70      // If neither Owner nor Platform provided authorization, make sure that it was
71      // provided by this index.
72      else if(authHandle != nvHandle)
73          return TPM_RC_NV_AUTHORIZATION;
74      return TPM_RC_SUCCESS;
75  }
```

7.5.2.3 NvClearOrderly()

This function is used to cause *gp.orderlyState* to be cleared to the non-orderly state.

```
76  TPM_RC
77  NvClearOrderly(
78      void
79      )
80  {
81      if(gp.orderlyState < SU_DA_USED_VALUE)
82          RETURN_IF_NV_IS_NOT_AVAILABLE;
83      g_clearOrderly = TRUE;
84      return TPM_RC_SUCCESS;
85  }
```

7.5.2.4 NvIsPinPassIndex()

Function to check to see if an NV index is a PIN Pass Index

Return Value	Meaning
TRUE(1)	is pin pass
FALSE(0)	is not pin pass

```
86  BOOL
87  NvIsPinPassIndex(
88      TPM_HANDLE          index       // IN: Handle to check
89      )
90  {
91      if(HandleGetType(index) == TPM_HT_NV_INDEX)
92      {
93          NV_INDEX                *nvIndex = NvGetIndexInfo(index, NULL);
94
95          return IsNvPinPassIndex(nvIndex->publicArea.attributes);
96      }
97      return FALSE;
98  }
```

7.6 Object Command Support (Object_spt.c)

7.6.1 Includes

```
1   #include "Tpm.h"
2   #include "Object_spt_fp.h"
```

7.6.2 Local Functions

7.6.2.1 GetIV2BSize()

Get the size of TPM2B_IV in canonical form that will be append to the start of the sensitive data. It includes both size of size field and size of iv data

```
3   static UINT16
4   GetIV2BSize(
5       OBJECT              *protector          // IN: the protector handle
6       )
7   {
8       TPM_ALG_ID          symAlg;
9       UINT16              keyBits;
10
11      // Determine the symmetric algorithm and size of key
12      if(protector == NULL)
13      {
14          // Use the context encryption algorithm and key size
15          symAlg = CONTEXT_ENCRYPT_ALG;
16          keyBits = CONTEXT_ENCRYPT_KEY_BITS;
17      }
18      else
19      {
20          symAlg = protector->publicArea.parameters.asymDetail.symmetric.algorithm;
21          keyBits = protector->publicArea.parameters.asymDetail.symmetric.keyBits.sym;
22      }
23
24      // The IV size is a UINT16 size field plus the block size of the symmetric
25      // algorithm
26      return sizeof(UINT16) + CryptGetSymmetricBlockSize(symAlg, keyBits);
27  }
```

7.6.2.2 ComputeProtectionKeyParms()

This function retrieves the symmetric protection key parameters for the sensitive data The parameters retrieved from this function include encryption algorithm, key size in bit, and a TPM2B_SYM_KEY containing the key material as well as the key size in bytes This function is used for any action that requires encrypting or decrypting of the sensitive area of an object or a credential blob

```
28  static void
29  ComputeProtectionKeyParms(
30      OBJECT          *protector,         // IN: the protector object
31      TPM_ALG_ID       hashAlg,           // IN: hash algorithm for KDFa
32      TPM2B           *name,              // IN: name of the object
33      TPM2B           *seedIn,            // IN: optional seed for duplication blob.
34                                          //     For non duplication blob, this
35                                          //     parameter should be NULL
36      TPM_ALG_ID      *symAlg,            // OUT: the symmetric algorithm
37      UINT16          *keyBits,           // OUT: the symmetric key size in bits
38      TPM2B_SYM_KEY   *symKey             // OUT: the symmetric key
39      )
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
40  {
41      const TPM2B          *seed = seedIn;
42
43      // Determine the algorithms for the KDF and the encryption/decryption
44      // For TPM_RH_NULL, using context settings
45      if(protector == NULL)
46      {
47          // Use the context encryption algorithm and key size
48          *symAlg = CONTEXT_ENCRYPT_ALG;
49          symKey->t.size = CONTEXT_ENCRYPT_KEY_BYTES;
50          *keyBits = CONTEXT_ENCRYPT_KEY_BITS;
51      }
52      else
53      {
54          TPMT_SYM_DEF_OBJECT *symDef;
55          symDef = &protector->publicArea.parameters.asymDetail.symmetric;
56          *symAlg = symDef->algorithm;
57          *keyBits = symDef->keyBits.sym;
58          symKey->t.size = (*keyBits + 7) / 8;
59      }
60      // Get seed for KDF
61      if(seed == NULL)
62          seed = GetSeedForKDF(protector);
63      // KDFa to generate symmetric key and IV value
64      CryptKDFa(hashAlg, seed, STORAGE_KEY, name, NULL,
65                symKey->t.size * 8, symKey->t.buffer, NULL, FALSE);
66      return;
67  }
```

7.6.2.3 ComputeOuterIntegrity()

The sensitive area parameter is a buffer that holds a space for the integrity value and the marshaled sensitive area. The caller should skip over the area set aside for the integrity value and compute the hash of the remainder of the object. The size field of sensitive is in unmarshaled form and the sensitive area contents is an array of bytes.

```
68  static void
69  ComputeOuterIntegrity(
70      TPM2B            *name,            // IN: the name of the object
71      OBJECT           *protector,       // IN: the object that
72                                         //     provides protection. For an object,
73                                         //     it is a parent. For a credential, it
74                                         //     is the encrypt object. For
75                                         //     a Temporary Object, it is NULL
76      TPMI_ALG_HASH     hashAlg,         // IN: algorithm to use for integrity
77      TPM2B            *seedIn,          // IN: an external seed may be provided for
78                                         //     duplication blob. For non duplication
79                                         //     blob, this parameter should be NULL
80      UINT32            sensitiveSize,   // IN: size of the marshaled sensitive data
81      BYTE             *sensitiveData,   // IN: sensitive area
82      TPM2B_DIGEST     *integrity        // OUT: integrity
83      )
84  {
85      HMAC_STATE        hmacState;
86      TPM2B_DIGEST      hmacKey;
87      const TPM2B      *seed = seedIn;
88  //
89      // Get seed for KDF
90      if(seed == NULL)
91          seed = GetSeedForKDF(protector);
92      // Determine the HMAC key bits
93      hmacKey.t.size = CryptHashGetDigestSize(hashAlg);
94
95      // KDFa to generate HMAC key
```

```
 96         CryptKDFa(hashAlg, seed, INTEGRITY_KEY, NULL, NULL,
 97                   hmacKey.t.size * 8, hmacKey.t.buffer, NULL, FALSE);
 98         // Start HMAC and get the size of the digest which will become the integrity
 99         integrity->t.size = CryptHmacStart2B(&hmacState, hashAlg, &hmacKey.b);
100
101         // Adding the marshaled sensitive area to the integrity value
102         CryptDigestUpdate(&hmacState.hashState, sensitiveSize, sensitiveData);
103
104         // Adding name
105         CryptDigestUpdate2B(&hmacState.hashState, name);
106
107         // Compute HMAC
108         CryptHmacEnd2B(&hmacState, &integrity->b);
109
110         return;
111     }
```

7.6.2.4 ComputeInnerIntegrity()

This function computes the integrity of an inner wrap

```
112     static void
113     ComputeInnerIntegrity(
114         TPM_ALG_ID       hashAlg,       // IN: hash algorithm for inner wrap
115         TPM2B           *name,          // IN: the name of the object
116         UINT16           dataSize,      // IN: the size of sensitive data
117         BYTE            *sensitiveData, // IN: sensitive data
118         TPM2B_DIGEST    *integrity      // OUT: inner integrity
119         )
120     {
121         HASH_STATE      hashState;
122     //
123         // Start hash and get the size of the digest which will become the integrity
124         integrity->t.size = CryptHashStart(&hashState, hashAlg);
125
126         // Adding the marshaled sensitive area to the integrity value
127         CryptDigestUpdate(&hashState, dataSize, sensitiveData);
128
129         // Adding name
130         CryptDigestUpdate2B(&hashState, name);
131
132         // Compute hash
133         CryptHashEnd2B(&hashState, &integrity->b);
134
135         return;
136     }
```

7.6.2.5 ProduceInnerIntegrity()

This function produces an inner integrity for regular private, credential or duplication blob It requires the sensitive data being marshaled to the *innerBuffer*, with the leading bytes reserved for integrity hash. It assume the sensitive data starts at address (*innerBuffer* + integrity size). This function integrity at the beginning of the inner buffer It returns the total size of buffer with the inner wrap

```
137     static UINT16
138     ProduceInnerIntegrity(
139         TPM2B           *name,          // IN: the name of the object
140         TPM_ALG_ID       hashAlg,       // IN: hash algorithm for inner wrap
141         UINT16           dataSize,      // IN: the size of sensitive data, excluding the
142                                         //     leading integrity buffer size
143         BYTE            *innerBuffer    // IN/OUT: inner buffer with sensitive data in
144                                         //     it.  At input, the leading bytes of this
```

```
145                                     //     buffer is reserved for integrity
146         )
147     {
148         BYTE            *sensitiveData; // pointer to the sensitive data
149         TPM2B_DIGEST     integrity;
150         UINT16           integritySize;
151         BYTE            *buffer;        // Auxiliary buffer pointer
152     //
153         // sensitiveData points to the beginning of sensitive data in innerBuffer
154         integritySize = sizeof(UINT16) + CryptHashGetDigestSize(hashAlg);
155         sensitiveData = innerBuffer + integritySize;
156
157         ComputeInnerIntegrity(hashAlg, name, dataSize, sensitiveData, &integrity);
158
159         // Add integrity at the beginning of inner buffer
160         buffer = innerBuffer;
161         TPM2B_DIGEST_Marshal(&integrity, &buffer, NULL);
162
163         return dataSize + integritySize;
164     }
```

7.6.2.6 CheckInnerIntegrity()

This function check integrity of inner blob

Error Returns	Meaning
TPM_RC_INTEGRITY	if the outer blob integrity is bad
errors	unmarshal errors while unmarshaling integrity

```
165     static TPM_RC
166     CheckInnerIntegrity(
167         TPM2B           *name,          // IN: the name of the object
168         TPM_ALG_ID       hashAlg,       // IN: hash algorithm for inner wrap
169         UINT16           dataSize,      // IN: the size of sensitive data, including the
170                                         //     leading integrity buffer size
171         BYTE            *innerBuffer    // IN/OUT: inner buffer with sensitive data in
172                                         //     it
173         )
174     {
175         TPM_RC          result;
176         TPM2B_DIGEST    integrity;
177         TPM2B_DIGEST    integrityToCompare;
178         BYTE            *buffer;                // Auxiliary buffer pointer
179         INT32           size;
180     //
181         // Unmarshal integrity
182         buffer = innerBuffer;
183         size = (INT32)dataSize;
184         result = TPM2B_DIGEST_Unmarshal(&integrity, &buffer, &size);
185         if(result == TPM_RC_SUCCESS)
186         {
187             // Compute integrity to compare
188             ComputeInnerIntegrity(hashAlg, name, (UINT16)size, buffer,
189                                   &integrityToCompare);
190             // Compare outer blob integrity
191             if(!MemoryEqual2B(&integrity.b, &integrityToCompare.b))
192                 result = TPM_RC_INTEGRITY;
193         }
194         return result;
195     }
```

```

7.6.3.2 AreAttributesForParent()

This function is called by create, load, and import functions.

NOTE: The *isParent* attribute is SET when an object is loaded and it has attributes that are suitable for a parent object.

Return Value	Meaning
TRUE(1)	properties are those of a parent
FALSE(0)	properties are not those of a parent

```
216  BOOL
217  ObjectIsParent(
218      OBJECT          *parentObject    // IN: parent handle
219      )
220  {
221      return parentObject->attributes.isParent;
222  }
```

7.6.3.3 CreateChecks()

Attribute checks that are unique to creation.

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*sensitiveDataOrigin* is not consistent with the object type
other	returns from PublicAttributesValidation()

```
223  TPM_RC
224  CreateChecks(
```

```
225         OBJECT                  *parentObject,
226         TPMT_PUBLIC             *publicArea,

```

7.6.3.4 SchemeChecks

This function is called by TPM2_LoadExternal() and PublicAttributesValidation(). This function validates the schemes in the public area of an object.

 Copyright © TCG 2006-2020

Error Returns	Meaning
TPM_RC_HASH	non-duplicable storage key and its parent have different name algorithm
TPM_RC_KDF	incorrect KDF specified for decrypting keyed hash object
TPM_RC_KEY	invalid key size values in an asymmetric key public area
TPM_RCS_SCHEME	inconsistent attributes *decrypt*, *sign*, *restricted* and key's scheme ID; or hash algorithm is inconsistent with the scheme ID for keyed hash object
TPM_RC_SYMMETRIC	a storage key with no symmetric algorithm specified; or non-storage key with symmetric algorithm different from TPM_ALG_NULL

```

7.6.3.5 PublicAttributesValidation()

This function validates the values in the public area of an object. This function is used in the processing of TPM2_Create(), TPM2_CreatePrimary(), TPM2_CreateLoaded(), TPM2_Load(), TPM2_Import(), and TPM2_LoadExternal(). For TPM2_Import() this is only used if the new parent has *fixedTPM* SET. For TPM2_LoadExternal(), this is not used for a public-only key

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*fixedTPM*, *fixedParent*, or *encryptedDuplication* attributes are inconsistent between themselves or with those of the parent object; inconsistent *restricted*, *decrypt* and *sign* attributes; attempt to inject sensitive data for an asymmetric key; attempt to create a symmetric cipher key that is not a decryption key
TPM_RC_HASH	*nameAlg* is TPM_ALG_NULL
TPM_RC_SIZE	*authPolicy* size does not match digest size of the name algorithm in *publicArea*
other	returns from SchemeChecks()

```
454  TPM_RC
455  PublicAttributesValidation(
456      OBJECT           *parentObject,   // IN: input parent object

7.6.3.8 ProduceOuterWrap()

This function produce outer wrap for a buffer containing the sensitive data. It requires the sensitive data being marshaled to the *outerBuffer*, with the leading bytes reserved for integrity hash. If iv is used, iv space should be reserved at the beginning of the buffer. It assumes the sensitive data starts at address (*outerBuffer* + integrity size [+ iv size]). This function performs:

a) Add IV before sensitive area if required

b) encrypt sensitive data, if iv is required, encrypt by iv. otherwise, encrypted by a NULL iv

c) add HMAC integrity at the beginning of the buffer It returns the total size of blob with outer wrap

```
610 UINT16
611 ProduceOuterWrap(
612     OBJECT          *protector,     // IN: The handle of the object that provides
613                                     //     protection.  For object, it is parent
614                                     //     handle. For credential, it is the handle
615                                     //     of encrypt object.
616     TPM2B           *name,          // IN: the name of the object
617     TPM_ALG_ID       hashAlg,       // IN: hash algorithm for outer wrap
618     TPM2B           *seed,          // IN: an external seed may be provided for
619                                     //     duplication blob. For non duplication
620                                     //     blob, this parameter should be NULL

```

7.6.3.15 SecretToCredential()

This function prepare the credential blob from a secret (a TPM2B_DIGEST) The operations in this function:

a) marshal TPM2B_DIGEST structure into the buffer of TPM2B_ID_OBJECT

b) encrypt the private buffer, excluding the leading integrity HMAC area

c) compute integrity HMAC and append to the beginning of the buffer.

d) Set the total size of TPM2B_ID_OBJECT buffer

```
1122    void
1123    SecretToCredential(
1124        TPM2B_DIGEST        *secret,        // IN: secret information
1125        TPM2B               *name,          // IN: the name of the object
1126        TPM2B               *seed,          // IN: an external seed.
1127        OBJECT              *protector,     // IN: the protector
1128        TPM2B_ID_OBJECT     *outIDObject    // OUT: output credential
1129        )
1130    {
1131        BYTE                *buffer;        // Auxiliary buffer pointer
1132        BYTE                *sensitiveData; // pointer to the sensitive data
1133        TPMI_ALG_HASH        outerHash;     // The hash algorithm for outer wrap
1134        UINT16               dataSize;      // data blob size
1135    //
1136        pAssert(secret != NULL && outIDObject != NULL);
```

 Copyright © TCG 2006-2020

```
1137
1138        // use protector's name algorithm as outer hash ????
1139        outerHash = protector->publicArea.nameAlg;
1140
1141        // Marshal secret area to credential buffer, leave space for integrity
1142        sensitiveData = outIDObject->t.credential
1143            + sizeof(UINT16) + CryptHashGetDigestSize(outerHash);
1144    // Marshal secret area
1145        buffer = sensitiveData;
1146        dataSize = TPM2B_DIGEST_Marshal(secret, &buffer, NULL);
1147
1148        // Apply outer wrap
1149        outIDObject->t.size = ProduceOuterWrap(protector, name, outerHash, seed, FALSE,
1150                                               dataSize, outIDObject->t.credential);
1151        return;
1152    }
```

7.6.3.16 CredentialToSecret()

Unwrap a credential. Check the integrity, decrypt and retrieve data to a TPM2B_DIGEST structure. The operations in this function:

a) check the integrity HMAC of the input credential area

b) decrypt the credential buffer

c) unmarshal TPM2B_DIGEST structure into the buffer of TPM2B_DIGEST

Error Returns	Meaning
TPM_RC_INSUFFICIENT	error during credential unmarshaling
TPM_RC_INTEGRITY	credential integrity is broken
TPM_RC_SIZE	error during credential unmarshaling
TPM_RC_VALUE	IV size does not match the encryption algorithm block size

```
1153    TPM_RC
1154    CredentialToSecret(
1155        TPM2B                *inIDObject,     // IN: input credential blob
1156        TPM2B                *name,           // IN: the name of the object
1157        TPM2B                *seed,           // IN: an external seed.
1158        OBJECT               *protector,      // IN: the protector
1159        TPM2B_DIGEST         *secret          // OUT: secret information
1160        )
1161    {
1162        TPM_RC                result;
1163        BYTE                 *buffer;
1164        INT32                 size;
1165        TPMI_ALG_HASH         outerHash;     // The hash algorithm for outer wrap
1166        BYTE                 *sensitiveData; // pointer to the sensitive data
1167        UINT16                dataSize;
1168    //
1169        // use protector's name algorithm as outer hash
1170        outerHash = protector->publicArea.nameAlg;
1171
1172        // Unwrap outer, a TPM_RC_INTEGRITY error may be returned at this point
1173        result = UnwrapOuter(protector, name, outerHash, seed, FALSE,
1174                             inIDObject->size, inIDObject->buffer);
1175        if(result == TPM_RC_SUCCESS)
1176        {
1177            // Compute the beginning of sensitive data
1178            sensitiveData = inIDObject->buffer
1179                + sizeof(UINT16) + CryptHashGetDigestSize(outerHash);
1180            dataSize = inIDObject->size
```

```
1181                - (sizeof(UINT16) + CryptHashGetDigestSize(outerHash));
1182            // Unmarshal secret buffer to TPM2B_DIGEST structure
1183            buffer = sensitiveData;
1184            size = (INT32)dataSize;
1185            result = TPM2B_DIGEST_Unmarshal(secret, &buffer, &size);
1186
1187            // If there were no other unmarshaling errors, make sure that the
1188            // expected amount of data was recovered
1189            if(result == TPM_RC_SUCCESS && size != 0)
1190                return TPM_RC_SIZE;
1191        }
1192        return result;
1193    }
```

7.6.3.17 MemoryRemoveTrailingZeros()

This function is used to adjust the length of an authorization value. It adjusts the size of the TPM2B so that it does not include octets at the end of the buffer that contain zero. The function returns the number of non-zero octets in the buffer.

```
1194    UINT16
1195    MemoryRemoveTrailingZeros(
1196        TPM2B_AUTH      *auth           // IN/OUT: value to adjust
1197        )
1198    {
1199        while((auth->t.size > 0) && (auth->t.buffer[auth->t.size - 1] == 0))
1200            auth->t.size--;
1201        return auth->t.size;
1202    }
```

7.6.3.18 SetLabelAndContext()

This function sets the label and context for a derived key. It is possible that *label* or *context* can end up being an Empty Buffer.

```
1203    TPM_RC
1204    SetLabelAndContext(
1205        TPMS_DERIVE             *labelContext,  // IN/OUT: the recovered label and
1206                                                //      context
1207        TPM2B_SENSITIVE_DATA    *sensitive      // IN: the sensitive data
1208        )
1209    {
1210        TPMS_DERIVE              sensitiveValue;
1211        TPM_RC                   result;
1212        INT32                    size;
1213        BYTE                    *buff;
1214    //
1215        // Unmarshal a TPMS_DERIVE from the TPM2B_SENSITIVE_DATA buffer
1216        // If there is something to unmarshal...
1217        if(sensitive->t.size != 0)
1218        {
1219            size = sensitive->t.size;
1220            buff = sensitive->t.buffer;
1221            result = TPMS_DERIVE_Unmarshal(&sensitiveValue, &buff, &size);
1222            if(result != TPM_RC_SUCCESS)
1223                return result;
1224            // If there was a label in the public area leave it there, otherwise, copy
1225            // the new value
1226            if(labelContext->label.t.size == 0)
1227                MemoryCopy2B(&labelContext->label.b, &sensitiveValue.label.b,
1228                             sizeof(labelContext->label.t.buffer));
1229            // if there was a context string in publicArea, it overrides
```

```
1230            if(labelContext->context.t.size == 0)
1231                MemoryCopy2B(&labelContext->context.b, &sensitiveValue.context.b,
1232                             sizeof(labelContext->label.t.buffer));
1233        }
1234        return TPM_RC_SUCCESS;
1235    }
```

7.6.3.19 UnmarshalToPublic()

Support function to unmarshal the template. This is used because the Input may be a TPMT_TEMPLATE and that structure does not have the same size as a TPMT_PUBLIC because of the difference between the *unique* and *seed* fields. If *derive* is not NULL, then the *seed* field is assumed to contain a *label* and *context* that are unmarshaled into *derive*.

```
1236    TPM_RC
1237    UnmarshalToPublic(
1238        TPMT_PUBLIC          *tOut,       // OUT: output
1239        TPM2B_TEMPLATE       *tIn,        // IN:
1240        BOOL                  derivation, // IN: indicates if this is for a derivation
1241        TPMS_DERIVE          *labelContext// OUT: label and context if derivation
1242        )
1243    {
1244        BYTE                 *buffer = tIn->t.buffer;
1245        INT32                 size = tIn->t.size;
1246        TPM_RC                result;
1247    //
1248        // make sure that tOut is zeroed so that there are no remnants from previous
1249        // uses
1250        MemorySet(tOut, 0, sizeof(TPMT_PUBLIC));
1251        // Unmarshal the components of the TPMT_PUBLIC up to the unique field
1252        result = TPMI_ALG_PUBLIC_Unmarshal(&tOut->type, &buffer, &size);
1253        if(result != TPM_RC_SUCCESS)
1254            return result;
1255        result = TPMI_ALG_HASH_Unmarshal(&tOut->nameAlg, &buffer, &size, FALSE);
1256        if(result != TPM_RC_SUCCESS)
1257            return result;
1258        result = TPMA_OBJECT_Unmarshal(&tOut->objectAttributes, &buffer, &size);
1259        if(result != TPM_RC_SUCCESS)
1260            return result;
1261        result = TPM2B_DIGEST_Unmarshal(&tOut->authPolicy, &buffer, &size);
1262        if(result != TPM_RC_SUCCESS)
1263            return result;
1264        result = TPMU_PUBLIC_PARMS_Unmarshal(&tOut->parameters, &buffer, &size,
1265                                             tOut->type);
1266        if(result != TPM_RC_SUCCESS)
1267            return result;
1268        // Now unmarshal a TPMS_DERIVE if this is for derivation
1269        if(derivation)
1270            result = TPMS_DERIVE_Unmarshal(labelContext, &buffer, &size);
1271        else
1272            // otherwise, unmarshal a TPMU_PUBLIC_ID
1273            result = TPMU_PUBLIC_ID_Unmarshal(&tOut->unique, &buffer, &size,
1274                                              tOut->type);
1275        // Make sure the template was used up
1276        if((result == TPM_RC_SUCCESS) && (size != 0))
1277            result = TPM_RC_SIZE;
1278        return result;
1279    }
```

7.6.3.20 ObjectSetExternal()

Set the external attributes for an object.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
1280 void
1281 ObjectSetExternal(
1282     OBJECT      *object
1283     )
1284 {
1285     object->attributes.external = SET;
1286 }
```

113      return result;
114  }
115  #endif // CC_EncryptDecrypt
```

7.8 ACT Support (ACT_spt.c)

7.8.1 Introduction

This code implements the ACT update code. It does not use a mutex. This code uses a platform service (_plat__ACT_UpdateCounter()) that returns *false* if the update is not accepted. If this occurs, then TPM_RC_RETRY should be sent to the caller so that they can retry the operation later. The implementation of this is platform dependent but the reference uses a simple flag to indicate that an update is pending and the only process that can clear that flag is the process that does the actual update.

7.8.2 Includes

```
1     #include "Tpm.h"
2     #include "ACT_spt_fp.h"
3     #include "Platform_fp.h"
```

7.8.3 Functions

7.8.3.1 _ActResume()

This function does the resume processing for an ACT. It updates the saved count and turns signaling back on if necessary.

```
4     static void
5     _ActResume(
6         UINT32              act,            //IN: the act number
7         ACT_STATE          *actData         //IN: pointer to the saved ACT data
8     )
9     {
10        // If the act was non-zero, then restore the counter value.
11        if(actData->remaining > 0)
12            _plat__ACT_UpdateCounter(act, actData->remaining);
13        // if the counter was zero and the ACT signaling, enable the signaling.
14        else if(go.signaledACT & (1 << act))
15            _plat__ACT_SetSignaled(act, TRUE);
16    }
```

7.8.3.2 ActStartup()

This function is called by TPM2_Startup() to initialize the ACT counter values.

```
17    BOOL
18    ActStartup(
19        STARTUP_TYPE        type
20    )
21    {
22        // Reset all the ACT hardware
23        _plat__ACT_Initialize();
24
25        // For TPM_RESET or TPM_RESTART, the ACTs will all be disabled and the output
26        // de-asserted.
27        if(type != SU_RESUME)
28        {
29            go.signaledACT = 0;
30    #define CLEAR_ACT_POLICY(N)                                                     \
31            go.ACT_##N.hashAlg = TPM_ALG_NULL;                                      \
32            go.ACT_##N.authPolicy.b.size = 0;
33
```

 Copyright © TCG 2006-2020

```
34            FOR_EACH_ACT(CLEAR_ACT_POLICY)
35
36        }
37        else
38        {
39            // Resume each of the implemented ACT
40    #define RESUME_ACT(N)    _ActResume(0x##N, &go.ACT_##N);
41
42            FOR_EACH_ACT(RESUME_ACT)
43        }
44        s_ActUpdated = 0;
45        _plat__ACT_EnableTicks(TRUE);
46        return TRUE;
47    }
```

7.8.3.3 _ActSaveState()

Get the counter state and the signaled state for an ACT. If the ACT has not been updated since the last time it was saved, then divide the count by 2.

```
48    static void
49    _ActSaveState(
50        UINT32              act,
51        P_ACT_STATE         actData
52    )
53    {
54        actData->remaining = _plat__ACT_GetRemaining(act);
55        // If the ACT hasn't been updated since the last startup, then it should be
56        // be halved.
57        if((s_ActUpdated & (1 << act)) == 0)
58        {
59            // Don't halve if the count is set to max or if halving would make it zero
60            if((actData->remaining != UINT32_MAX) && (actData->remaining > 1))
61                actData->remaining /= 2;
62        }
63        if(_plat__ACT_GetSignaled(act))
64            go.signaledACT |= (1 << act);
65    }
```

7.8.3.4 ActGetSignaled()

This function returns the state of the signaled flag associated with an ACT.

```
66    BOOL
67    ActGetSignaled(
68        TPM_RH              actHandle
69    )
70    {
71        UINT32              act = actHandle - TPM_RH_ACT_0;
72    //
73        return _plat__ACT_GetSignaled(act);
74    }
```

7.8.3.5 ActShutdown()

This function saves the current state of the counters

```
75    BOOL
76    ActShutdown(
77        TPM_SU              state       //IN: the type of the shutdown.
78    )
```

```
79  {
80      // if this is not shutdown state, then the only type of startup is TPM_RESTART
81      // so the timer values will be cleared. If this is shutdown state, get the current
82      // countdown and signaled values. Plus, if the counter has not been updated
83      // since the last restart, divide the time by 2 so that there is no attack on the
84      // countdown by saving the countdown state early and then not using the TPM.
85      if(state == TPM_SU_STATE)
86      {
87          // This will be populated as each of the ACT is queried
88          go.signaledACT = 0;
89          // Get the current count and the signaled state
90  #define SAVE_ACT_STATE(N) _ActSaveState(0x##N, &go.ACT_##N);
91
92          FOR_EACH_ACT(SAVE_ACT_STATE);
93      }
94      return TRUE;
95  }
```

7.8.3.6 ActIsImplemented()

This function determines if an ACT is implemented in both the TPM and the platform code.

```
96  BOOL
97  ActIsImplemented(
98      UINT32          act
99  )
100 {
101 #define CASE_ACT_
102     // This switch accounts for the TPM implemente values.
103     switch(act)
104     {
105         FOR_EACH_ACT(CASE_ACT_NUMBER)
106             // This ensures that the platorm implementes the values implemented by
107             // the TPM
108             return _plat__ACT_GetImplemented(act);
109         default:
110             break;
111     }
112     return FALSE;
113 }
```

7.8.3.7 ActCounterUpdate()

This function updates the ACT counter. If the counter already has a pending update, it returns TPM_RC_RETRY so that the update can be tried again later.

```
114 TPM_RC
115 ActCounterUpdate(
116     TPM_RH          handle,         //IN: the handle of the act
117     UINT32          newValue        //IN: the value to set in the ACT
118 )
119 {
120     UINT32          act;
121     TPM_RC          result;
122 //
123     act = handle - TPM_RH_ACT_0;
124     // This should never fail, but...
125     if(!_plat__ACT_GetImplemented(act))
126         result = TPM_RC_VALUE;
127     else
128     {
129     // Will need to clear orderly so fail if we are orderly and NV is not available
130         if(NV_IS_ORDERLY)
```

```
131                 RETURN_IF_NV_IS_NOT_AVAILABLE;
132             // if the attempt to update the counter fails, it means that there is an
133             // update pending so wait until it has occurred and then do an update.
134             if(!_plat__ACT_UpdateCounter(act, newValue))
135                 result = TPM_RC_RETRY;
136             else
137             {
138                 // Indicate that the ACT has been updated since last TPM2_Startup().
139                 s_ActUpdated |= (UINT16)(1 << act);
140
141                 // Need to clear the orderly flag
142                 g_clearOrderly = TRUE;
143
144                 result = TPM_RC_SUCCESS;
145             }
146         }
147         return result;
148     }
```

7.8.3.8 ActGetCapabilityData()

This function returns the list of ACT data

Return Value	Meaning
YES	if more ACT data is available
NO	if no more ACT data to

```
149 TPMI_YES_NO
150 ActGetCapabilityData(
151     TPM_HANDLE       actHandle,     // IN: the handle for the starting ACT
152     UINT32           maxCount,      // IN: maximum allowed return values
153     TPML_ACT_DATA   *actList        // OUT: ACT data list
154 )
155 {
156     // Initialize output property list
157     actList->count = 0;
158
159     // Make sure that the starting handle value is in range (again)
160     if((actHandle < TPM_RH_ACT_0) || (actHandle > TPM_RH_ACT_F))
161         return FALSE;
162     // The maximum count of curves we may return is MAX_ECC_CURVES
163     if(maxCount > MAX_ACT_DATA)
164         maxCount = MAX_ACT_DATA;
165     // Scan the ACT data from the starting ACT
166     for(; actHandle <= TPM_RH_ACT_F; actHandle++)
167     {
168         UINT32          act = actHandle - TPM_RH_ACT_0;
169         if(actList->count < maxCount)
170         {
171             if(ActIsImplemented(act))
172             {
173                 TPMS_ACT_DATA    *actData = &actList->actData[actList->count];
174             //
175                 memset(&actData->attributes, 0, sizeof(actData->attributes));
176                 actData->handle = actHandle;
177                 actData->timeout = _plat__ACT_GetRemaining(act);
178                 actData->attributes.signaled = _plat__ACT_GetSignaled(act);
179                 actList->count++;
180             }
181         }
182         else
183         {
```

```
184             if(_plat__ACT_GetImplemented(act))
185                 return YES;
186         }
187     }
188     // If we get here, either all of the ACT values were put in the list, or the list
189     // was filled and there are no more ACT values to return
190     return NO;
191 }
```

8 Subsystem

8.1 CommandAudit.c

8.1.1 Introduction

This file contains the functions that support command audit.

8.1.2 Includes

```
1   #include "Tpm.h"
```

8.1.3 Functions

8.1.3.1 CommandAuditPreInstall_Init()

This function initializes the command audit list. This function simulates the behavior of manufacturing. A function is used instead of a structure definition because this is easier than figuring out the initialization value for a bit array.

This function would not be implemented outside of a manufacturing or simulation environment.

```
2   void
3   CommandAuditPreInstall_Init(
4       void
5       )
6   {
7       // Clear all the audit commands
8       MemorySet(gp.auditCommands, 0x00, sizeof(gp.auditCommands));
9
10      // TPM_CC_SetCommandCodeAuditStatus always being audited
11      CommandAuditSet(TPM_CC_SetCommandCodeAuditStatus);
12
13      // Set initial command audit hash algorithm to be context integrity hash
14      // algorithm
15      gp.auditHashAlg = CONTEXT_INTEGRITY_HASH_ALG;
16
17      // Set up audit counter to be 0
18      gp.auditCounter = 0;
19
20      // Write command audit persistent data to NV
21      NV_SYNC_PERSISTENT(auditCommands);
22      NV_SYNC_PERSISTENT(auditHashAlg);
23      NV_SYNC_PERSISTENT(auditCounter);
24
25      return;
26  }
```

8.1.3.2 CommandAuditStartup()

This function clears the command audit digest on a TPM Reset.

```
27  BOOL
28  CommandAuditStartup(
29      STARTUP_TYPE     type            // IN: start up type
30      )
31  {
32      if((type != SU_RESTART) && (type != SU_RESUME))
```

 Copyright © TCG 2006-2020

```
33          {
34              // Reset the digest size to initialize the digest
35              gr.commandAuditDigest.t.size = 0;
36          }
37          return TRUE;
38      }
```

8.1.3.3 CommandAuditSet()

This function will SET the audit flag for a command. This function will not SET the audit flag for a command that is not implemented. This ensures that the audit status is not SET when TPM2_GetCapability() is used to read the list of audited commands.

This function is only used by TPM2_SetCommandCodeAuditStatus().

The actions in TPM2_SetCommandCodeAuditStatus() are expected to cause the changes to be saved to NV after it is setting and clearing bits.

Return Value	Meaning
TRUE(1)	command code audit status was changed
FALSE(0)	command code audit status was not changed

```
39      BOOL
40      CommandAuditSet(
41          TPM_CC            commandCode      // IN: command code
42          )
43      {
44          COMMAND_INDEX        commandIndex = CommandCodeToCommandIndex(commandCode);
45
46          // Only SET a bit if the corresponding command is implemented
47          if(commandIndex != UNIMPLEMENTED_COMMAND_INDEX)
48          {
49              // Can't audit shutdown
50              if(commandCode != TPM_CC_Shutdown)
51              {
52                  if(!TEST_BIT(commandIndex, gp.auditCommands))
53                  {
54                      // Set bit
55                      SET_BIT(commandIndex, gp.auditCommands);
56                      return TRUE;
57                  }
58              }
59          }
60          // No change
61          return FALSE;
62      }
```

8.1.3.4 CommandAuditClear()

This function will CLEAR the audit flag for a command. It will not CLEAR the audit flag for TPM_CC_SetCommandCodeAuditStatus().

This function is only used by TPM2_SetCommandCodeAuditStatus().

The actions in TPM2_SetCommandCodeAuditStatus() are expected to cause the changes to be saved to NV after it is setting and clearing bits.

Return Value	Meaning
TRUE(1)	command code audit status was changed
FALSE(0)	command code audit status was not changed

```
63  BOOL
64  CommandAuditClear(
65      TPM_CC              commandCode     // IN: command code
66      )
67  {
68      COMMAND_INDEX       commandIndex = CommandCodeToCommandIndex(commandCode);
69
70      // Do nothing if the command is not implemented
71      if(commandIndex != UNIMPLEMENTED_COMMAND_INDEX)
72      {
73          // The bit associated with TPM_CC_SetCommandCodeAuditStatus() cannot be
74          // cleared
75          if(commandCode != TPM_CC_SetCommandCodeAuditStatus)
76          {
77              if(TEST_BIT(commandIndex, gp.auditCommands))
78              {
79                  // Clear bit
80                  CLEAR_BIT(commandIndex, gp.auditCommands);
81                  return TRUE;
82              }
83          }
84      }
85      // No change
86      return FALSE;
87  }
```

8.1.3.5 CommandAuditIsRequired()

This function indicates if the audit flag is SET for a command.

Return Value	Meaning
TRUE(1)	command is audited
FALSE(0)	command is not audited

```
88  BOOL
89  CommandAuditIsRequired(
90      COMMAND_INDEX       commandIndex    // IN: command index
91      )
92  {
93      // Check the bit map.  If the bit is SET, command audit is required
94      return(TEST_BIT(commandIndex, gp.auditCommands));
95  }
```

8.1.3.6 CommandAuditCapGetCCList()

This function returns a list of commands that have their audit bit SET.

The list starts at the input *commandCode*.

 Copyright © TCG 2006-2020

Return Value	Meaning
YES	if there are more command code available
NO	all the available command code has been returned

```
 96  TPMI_YES_NO
 97  CommandAuditCapGetCCList(
 98      TPM_CC           commandCode,    // IN: start command code
 99      UINT32           count,          // IN: count of returned TPM_CC
100      TPML_CC         *commandList     // OUT: list of TPM_CC
101      )
102  {
103      TPMI_YES_NO     more = NO;
104      COMMAND_INDEX   commandIndex;
105
106      // Initialize output handle list
107      commandList->count = 0;
108
109      // The maximum count of command we may return is MAX_CAP_CC
110      if(count > MAX_CAP_CC) count = MAX_CAP_CC;
111
112      // Find the implemented command that has a command code that is the same or
113      // higher than the input
114      // Collect audit commands
115      for(commandIndex = GetClosestCommandIndex(commandCode);
116      commandIndex != UNIMPLEMENTED_COMMAND_INDEX;
117          commandIndex = GetNextCommandIndex(commandIndex))
118      {
119          if(CommandAuditIsRequired(commandIndex))
120          {
121              if(commandList->count < count)
122              {
123                  // If we have not filled up the return list, add this command
124                  // code to its
125                  TPM_CC      cc = GET_ATTRIBUTE(s_ccAttr[commandIndex],
126                                                 TPMA_CC, commandIndex);
127                  if(IS_ATTRIBUTE(s_ccAttr[commandIndex], TPMA_CC, V))
128                      cc += (1 << 29);
129                  commandList->commandCodes[commandList->count] = cc;
130                  commandList->count++;
131              }
132              else
133              {
134                  // If the return list is full but we still have command
135                  // available, report this and stop iterating
136                  more = YES;
137                  break;
138              }
139          }
140      }
141
142      return more;
143  }
```

8.1.3.7 CommandAuditGetDigest

This command is used to create a digest of the commands being audited. The commands are processed in ascending numeric order with a list of TPM_CC being added to a hash. This operates as if all the audited command codes were concatenated and then hashed.

```
144  void
145  CommandAuditGetDigest(
```

 Copyright © TCG 2006-2020

```
146         TPM2B_DIGEST     *digest          // OUT: command digest
147         )
148     {
149         TPM_CC                          commandCode;
150         COMMAND_INDEX                   commandIndex;
151         HASH_STATE                      hashState;
152
153         // Start hash
154         digest->t.size = CryptHashStart(&hashState, gp.auditHashAlg);
155
156         // Add command code
157         for(commandIndex = 0; commandIndex < COMMAND_COUNT; commandIndex++)
158         {
159             if(CommandAuditIsRequired(commandIndex))
160             {
161                 commandCode = GetCommandCode(commandIndex);
162                 CryptDigestUpdateInt(&hashState, sizeof(commandCode), commandCode);
163             }
164         }
165
166         // Complete hash
167         CryptHashEnd2B(&hashState, &digest->b);
168
169         return;
170     }
```

8.2 DA.c

8.2.1 Introduction

This file contains the functions and data definitions relating to the dictionary attack logic.

8.2.2 Includes and Data Definitions

```
1   #define DA_C
2   #include "Tpm.h"
```

8.2.3 Functions

8.2.3.1 DAPreInstall_Init()

This function initializes the DA parameters to their manufacturer-default values. The default values are determined by a platform-specific specification.

This function should not be called outside of a manufacturing or simulation environment.

The DA parameters will be restored to these initial values by TPM2_Clear().

```
3   void
4   DAPreInstall_Init(
5       void
6       )
7   {
8       gp.failedTries = 0;
9       gp.maxTries = 3;
10      gp.recoveryTime = 1000;          // in seconds (~16.67 minutes)
11      gp.lockoutRecovery = 1000;       // in seconds
12      gp.lockOutAuthEnabled = TRUE;    // Use of lockoutAuth is enabled
13
14      // Record persistent DA parameter changes to NV
15      NV_SYNC_PERSISTENT(failedTries);
16      NV_SYNC_PERSISTENT(maxTries);
17      NV_SYNC_PERSISTENT(recoveryTime);
18      NV_SYNC_PERSISTENT(lockoutRecovery);
19      NV_SYNC_PERSISTENT(lockOutAuthEnabled);
20
21      return;
22  }
```

8.2.3.2 DAStartup()

This function is called by TPM2_Startup() to initialize the DA parameters. In the case of Startup(CLEAR), use of *lockoutAuth* will be enabled if the lockout recovery time is 0. Otherwise, *lockoutAuth* will not be enabled until the TPM has been continuously powered for the *lockoutRecovery* time.

This function requires that NV be available and not rate limiting.

```
23  BOOL
24  DAStartup(
25      STARTUP_TYPE     type            // IN: startup type
26      )
27  {
28      NOT_REFERENCED(type);
29  #if !ACCUMULATE_SELF_HEAL_TIMER
30      _plat__TimerWasReset();
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
31          s_selfHealTimer = 0;
32          s_lockoutTimer = 0;
33      #else
34          if(_plat__TimerWasReset())
35          {
36              if(!NV_IS_ORDERLY)
37              {
38                  // If shutdown was not orderly, then don't really know if go.time has
39                  // any useful value so reset the timer to 0. This is what the tick
40                  // was reset to
41                  s_selfHealTimer = 0;
42                  s_lockoutTimer = 0;
43              }
44              else
45              {
46                  // If we know how much time was accumulated at the last orderly shutdown
47                  // subtract that from the saved timer values so that they effectively
48                  // have the accumulated values
49                  s_selfHealTimer -= go.time;
50                  s_lockoutTimer -= go.time;
51              }
52          }
53      #endif
54
55          // For any Startup(), if lockoutRecovery is 0, enable use of lockoutAuth.
56          if(gp.lockoutRecovery == 0)
57          {
58              gp.lockOutAuthEnabled = TRUE;
59              // Record the changes to NV
60              NV_SYNC_PERSISTENT(lockOutAuthEnabled);
61          }
62
63          // If DA has not been disabled and the previous shutdown is not orderly
64          // failedTries is not already at its maximum then increment 'failedTries'
65          if(gp.recoveryTime != 0
66             && gp.failedTries < gp.maxTries
67             && !IS_ORDERLY(g_prevOrderlyState))
68          {
69      #if USE_DA_USED
70              gp.failedTries += g_daUsed;
71              g_daUsed = FALSE;
72      #else
73              gp.failedTries++;
74      #endif
75              // Record the change to NV
76              NV_SYNC_PERSISTENT(failedTries);
77          }
78          // Before Startup, the TPM will not do clock updates. At startup, need to
79          // do a time update which will do the DA update.
80          TimeUpdate();
81
82          return TRUE;
83      }
```

8.2.3.3 DARegisterFailure()

This function is called when a authorization failure occurs on an entity that is subject to dictionary-attack protection. When a DA failure is triggered, register the failure by resetting the relevant self-healing timer to the current time.

```
84      void
85      DARegisterFailure(
86          TPM_HANDLE          handle          // IN: handle for failure
87          )
```

```
88  {
89      // Reset the timer associated with lockout if the handle is the lockoutAuth.
90      if(handle == TPM_RH_LOCKOUT)
91          s_lockoutTimer = g_time;
92      else
93          s_selfHealTimer = g_time;
94      return;
95  }
```

8.2.3.4 DASelfHeal()

This function is called to check if sufficient time has passed to allow decrement of *failedTries* or to re-enable use of *lockoutAuth*.

This function should be called when the time interval is updated.

```
96  void
97  DASelfHeal(
98      void
99      )
100 {
101     // Regular authorization self healing logic
102     // If no failed authorization tries, do nothing.  Otherwise, try to
103     // decrease failedTries
104     if(gp.failedTries != 0)
105     {
106         // if recovery time is 0, DA logic has been disabled.  Clear failed tries
107         // immediately
108         if(gp.recoveryTime == 0)
109         {
110             gp.failedTries = 0;
111             // Update NV record
112             NV_SYNC_PERSISTENT(failedTries);
113         }
114         else
115         {
116             UINT64          decreaseCount;
117 #if 0 // Errata eliminates this code
118             // In the unlikely event that failedTries should become larger than
119             // maxTries
120             if(gp.failedTries > gp.maxTries)
121                 gp.failedTries = gp.maxTries;
122 #endif
123             // How much can failedTries be decreased
124
125             // Cast s_selfHealTimer to an int in case it became negative at
126             // startup
127             decreaseCount = ((g_time - (INT64)s_selfHealTimer) / 1000)
128                 / gp.recoveryTime;
129
130             if(gp.failedTries <= (UINT32)decreaseCount)
131                 // should not set failedTries below zero
132                 gp.failedTries = 0;
133             else
134                 gp.failedTries -= (UINT32)decreaseCount;
135
136             // the cast prevents overflow of the product
137             s_selfHealTimer += (decreaseCount * (UINT64)gp.recoveryTime) * 1000;
138             if(decreaseCount != 0)
139                 // If there was a change to the failedTries, record the changes
140                 // to NV
141                 NV_SYNC_PERSISTENT(failedTries);
142         }
143     }
```

157                 gp.lockOutAuthEnabled = TRUE;
158                 // Record the changes to NV
159                 NV_SYNC_PERSISTENT(lockOutAuthEnabled);
160             }
161         }
162     }
163     return;
164 }
```

8.3 Hierarchy.c

8.3.1 Introduction

This file contains the functions used for managing and accessing the hierarchy-related values.

8.3.2 Includes

```
1   #include "Tpm.h"
```

8.3.3 Functions

8.3.3.1 HierarchyPreInstall()

This function performs the initialization functions for the hierarchy when the TPM is simulated. This function should not be called if the TPM is not in a manufacturing mode at the manufacturer, or in a simulated environment.

```
2   void
3   HierarchyPreInstall_Init(
4       void
5       )
6   {
7       // Allow lockout clear command
8       gp.disableClear = FALSE;
9
10      // Initialize Primary Seeds
11      gp.EPSeed.t.size = sizeof(gp.EPSeed.t.buffer);
12      gp.SPSeed.t.size = sizeof(gp.SPSeed.t.buffer);
13      gp.PPSeed.t.size = sizeof(gp.PPSeed.t.buffer);
14  #if (defined USE_PLATFORM_EPS) && (USE_PLATFORM_EPS != NO)
15      _plat__GetEPS(gp.EPSeed.t.size, gp.EPSeed.t.buffer);
16  #else
17      CryptRandomGenerate(gp.EPSeed.t.size, gp.EPSeed.t.buffer);
18  #endif
19      CryptRandomGenerate(gp.SPSeed.t.size, gp.SPSeed.t.buffer);
20      CryptRandomGenerate(gp.PPSeed.t.size, gp.PPSeed.t.buffer);
21
22      // Initialize owner, endorsement and lockout authorization
23      gp.ownerAuth.t.size = 0;
24      gp.endorsementAuth.t.size = 0;
25      gp.lockoutAuth.t.size = 0;
26
27      // Initialize owner, endorsement, and lockout policy
28      gp.ownerAlg = TPM_ALG_NULL;
29      gp.ownerPolicy.t.size = 0;
30      gp.endorsementAlg = TPM_ALG_NULL;
31      gp.endorsementPolicy.t.size = 0;
32      gp.lockoutAlg = TPM_ALG_NULL;
33      gp.lockoutPolicy.t.size = 0;
34
35      // Initialize ehProof, shProof and phProof
36      gp.phProof.t.size = sizeof(gp.phProof.t.buffer);
37      gp.shProof.t.size = sizeof(gp.shProof.t.buffer);
38      gp.ehProof.t.size = sizeof(gp.ehProof.t.buffer);
39      CryptRandomGenerate(gp.phProof.t.size, gp.phProof.t.buffer);
40      CryptRandomGenerate(gp.shProof.t.size, gp.shProof.t.buffer);
41      CryptRandomGenerate(gp.ehProof.t.size, gp.ehProof.t.buffer);
42

56      NV_SYNC_PERSISTENT(lockoutPolicy);
57      NV_SYNC_PERSISTENT(phProof);
58      NV_SYNC_PERSISTENT(shProof);
59      NV_SYNC_PERSISTENT(ehProof);
60
61      return;
62  }
```

8.3.3.2 HierarchyStartup()

This function is called at TPM2_Startup() to initialize the hierarchy related values.

```
63  BOOL
64  HierarchyStartup(
65      STARTUP_TYPE     type             // IN: start up type
66      )
67  {
68      // phEnable is SET on any startup
69      g_phEnable = TRUE;
70
71      // Reset platformAuth, platformPolicy; enable SH and EH at TPM_RESET and
72      // TPM_RESTART
73      if(type != SU_RESUME)
74      {
75          gc.platformAuth.t.size = 0;
76          gc.platformPolicy.t.size = 0;
77          gc.platformAlg = TPM_ALG_NULL;
78
79          // enable the storage and endorsement hierarchies and the platformNV
80          gc.shEnable = gc.ehEnable = gc.phEnableNV = TRUE;
81      }
82
83      // nullProof and nullSeed are updated at every TPM_RESET
84      if((type != SU_RESTART) && (type != SU_RESUME))
85      {
86          gr.nullProof.t.size = sizeof(gr.nullProof.t.buffer);
87          CryptRandomGenerate(gr.nullProof.t.size, gr.nullProof.t.buffer);
88          gr.nullSeed.t.size = sizeof(gr.nullSeed.t.buffer);
89          CryptRandomGenerate(gr.nullSeed.t.size, gr.nullSeed.t.buffer);
90      }
91
92      return TRUE;
93  }
```

8.3.3.3 HierarchyGetProof()

This function finds the proof value associated with a hierarchy.It returns a pointer to the proof value.

```
94  TPM2B_PROOF *
95  HierarchyGetProof(
96      TPMI_RH_HIERARCHY    hierarchy      // IN: hierarchy constant
```

```
97       )
98   {
99       TPM2B_PROOF          *proof = NULL;
100
101      switch(hierarchy)
102      {
103          case TPM_RH_PLATFORM:
104              // phProof for TPM_RH_PLATFORM
105              proof = &gp.phProof;
106              break;
107          case TPM_RH_ENDORSEMENT:
108              // ehProof for TPM_RH_ENDORSEMENT
109              proof = &gp.ehProof;
110              break;
111          case TPM_RH_OWNER:
112              // shProof for TPM_RH_OWNER
113              proof = &gp.shProof;
114              break;
115          default:
116              // nullProof for TPM_RH_NULL or anything else
117              proof = &gr.nullProof;
118              break;
119      }
120      return proof;
121  }
```

8.3.3.4 HierarchyGetPrimarySeed()

This function returns the primary seed of a hierarchy.

```
122  TPM2B_SEED *
123  HierarchyGetPrimarySeed(
124      TPMI_RH_HIERARCHY    hierarchy      // IN: hierarchy
125      )
126  {
127      TPM2B_SEED           *seed = NULL;
128      switch(hierarchy)
129      {
130          case TPM_RH_PLATFORM:
131              seed = &gp.PPSeed;
132              break;
133          case TPM_RH_OWNER:
134              seed = &gp.SPSeed;
135              break;
136          case TPM_RH_ENDORSEMENT:
137              seed = &gp.EPSeed;
138              break;
139           default:
140              seed = &gr.nullSeed;
141              break;
142      }
143      return seed;
144  }
```

8.3.3.5 HierarchyIsEnabled()

This function checks to see if a hierarchy is enabled.

NOTE: The TPM_RH_NULL hierarchy is always enabled.

Return Value	Meaning
TRUE(1)	hierarchy is enabled
FALSE(0)	hierarchy is disabled

```
145  BOOL
146  HierarchyIsEnabled(
147      TPMI_RH_HIERARCHY    hierarchy      // IN: hierarchy
148      )
149  {
150      BOOL             enabled = FALSE;
151
152      switch(hierarchy)
153      {
154          case TPM_RH_PLATFORM:
155              enabled = g_phEnable;
156              break;
157          case TPM_RH_OWNER:
158              enabled = gc.shEnable;
159              break;
160          case TPM_RH_ENDORSEMENT:
161              enabled = gc.ehEnable;
162              break;
163          case TPM_RH_NULL:
164              enabled = TRUE;
165              break;
166          default:
167              enabled = FALSE;
168              break;
169      }
170      return enabled;
171  }
```

8.4 NvDynamic.c

8.4.1 Introduction

The NV memory is divided into two area: dynamic space for user defined NV indexes and evict objects, and reserved space for TPM persistent and state save data.

The entries in dynamic space are a linked list of entries. Each entry has, as its first field, a size. If the size field is zero, it marks the end of the list.

An Index allocation will contain an NV_INDEX structure. If the Index does not have the orderly attribute, the NV_INDEX is followed immediately by the NV data.

An evict object entry contains a handle followed by an OBJECT structure. This results in both the Index and Evict Object having an identifying handle as the first field following the size field.

When an Index has the orderly attribute, the data is kept in RAM. This RAM is saved to backing store in NV memory on any orderly shutdown. The entries in orderly memory are also a linked list using a size field as the first entry.

The attributes of an orderly index are maintained in RAM memory in order to reduce the number of NV writes needed for orderly data. When an orderly index is created, an entry is made in the dynamic NV memory space that holds the Index authorizations (*authPolicy* and *authValue*) and the size of the data. This entry is only modified if the *authValue* of the index is changed. The more volatile data of the index is kept in RAM. When an orderly Index is created or deleted, the RAM data is copied to NV backing store so that the image in the backing store matches the layout of RAM. In normal operation. The RAM data is also copied on any orderly shutdown. In normal operation, the only other reason for writing to the backing store for RAM is when a counter is first written (TPMA_NV_WRITTEN changes from CLEAR to SET) or when a counter "rolls over."

Static space contains items that are individually modifiable. The values are in the *gp* PERSISTEND_DATA structure in RAM and mapped to locations in NV.

8.4.2 Includes, Defines and Data Definitions

```
1    #define NV_C
2    #include "Tpm.h"
```

8.4.3 Local Functions

8.4.3.1 NvNext()

This function provides a method to traverse every data entry in NV dynamic area.

To begin with, parameter *iter* should be initialized to NV_REF_INIT indicating the first element. Every time this function is called, the value in *iter* would be adjusted pointing to the next element in traversal. If there is no next element, *iter* value would be 0. This function returns the address of the 'data entry' pointed by the *iter*. If there is no more element in the set, a 0 value is returned indicating the end of traversal.

```
3    static NV_REF
4    NvNext(
5        NV_REF          *iter,          // IN/OUT: the list iterator
6        TPM_HANDLE      *handle         // OUT: the handle of the next item.
7        )
8    {
9        NV_REF                  currentAddr;
10       NV_ENTRY_HEADER         header;
11   //
12       // If iterator is at the beginning of list
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
13      if(*iter == NV_REF_INIT)
14      {
15          // Initialize iterator
16          *iter = NV_USER_DYNAMIC;
17      }
18      // Step over the size field and point to the handle
19      currentAddr = *iter + sizeof(UINT32);
20
21      // read the header of the next entry
22      NvRead(&header, *iter, sizeof(NV_ENTRY_HEADER));
23
24      // if the size field is zero, then we have hit the end of the list
25      if(header.size == 0)
26          // leave the *iter pointing at the end of the list
27          return 0;
28      // advance the header by the size of the entry
29      *iter += header.size;
30
31      if(handle != NULL)
32          *handle = header.handle;
33      return currentAddr;
34  }
```

8.4.3.2 NvNextByType()

This function returns a reference to the next NV entry of the desired type

Return Value	Meaning
0	end of list
0	the next entry of the indicated type

```
35  static NV_REF
36  NvNextByType(
37      TPM_HANDLE      *handle,        // OUT: the handle of the found type
38      NV_REF          *iter,          // IN: the iterator
39      TPM_HT           type           // IN: the handle type to look for
40      )
41  {
42      NV_REF           addr;
43      TPM_HANDLE       nvHandle;
44  //
45      while((addr = NvNext(iter, &nvHandle)) != 0)
46      {
47          // addr: the address of the location containing the handle of the value
48          // iter: the next location.
49          if(HandleGetType(nvHandle) == type)
50              break;
51      }
52      if(handle != NULL)
53          *handle = nvHandle;
54      return addr;
55  }
```

8.4.3.3 NvNextIndex()

This function returns the reference to the next NV Index entry. A value of 0 indicates the end of the list.

 Copyright © TCG 2006-2020

Return Value	Meaning
0	end of list
0	the next reference

```
56  #define NvNextIndex(handle, iter)                     \
57      NvNextByType(handle, iter, TPM_HT_NV_INDEX)
```

8.4.3.4 NvNextEvict()

This function returns the offset in NV of the next evict object entry. A value of 0 indicates the end of the list.

```
58  #define NvNextEvict(handle, iter)                     \
59      NvNextByType(handle, iter, TPM_HT_PERSISTENT)
```

8.4.3.5 NvGetEnd()

Function to find the end of the NV dynamic data list

```
60  static NV_REF
61  NvGetEnd(
62      void
63      )
64  {
65      NV_REF          iter = NV_REF_INIT;
66      NV_REF          currentAddr;
67  //
68      // Scan until the next address is 0
69      while((currentAddr = NvNext(&iter, NULL)) != 0);
70      return iter;
71  }
```

8.4.3.6 NvGetFreeBytes

This function returns the number of free octets in NV space.

```
72  static UINT32
73  NvGetFreeBytes(
74      void
75      )
76  {
77      // This does not have an overflow issue because NvGetEnd() cannot return a value
78      // that is larger than s_evictNvEnd. This is because there is always a 'stop'
79      // word in the NV memory that terminates the search for the end before the
80      // value can go past s_evictNvEnd.
81      return s_evictNvEnd - NvGetEnd();
82  }
```

8.4.3.7 NvTestSpace()

This function will test if there is enough space to add a new entity.

 Copyright © TCG 2006-2020

Return Value	Meaning
TRUE(1)	space available
FALSE(0)	no enough space

```
83   static BOOL
84   NvTestSpace(
85       UINT32            size,          // IN: size of the entity to be added
86       BOOL              isIndex,       // IN: TRUE if the entity is an index
87       BOOL              isCounter      // IN: TRUE if the index is a counter
88       )
89   {
90       UINT32       remainBytes = NvGetFreeBytes();
91       UINT32       reserved = sizeof(UINT32)       // size of the forward pointer
92           + sizeof(NV_LIST_TERMINATOR);
93   //
94       // Do a compile time sanity check on the setting for NV_MEMORY_SIZE
95   #if NV_MEMORY_SIZE < 1024
96   #error "NV_MEMORY_SIZE probably isn't large enough"
97   #endif
98
99       // For NV Index, need to make sure that we do not allocate an Index if this
100      // would mean that the TPM cannot allocate the minimum number of evict
101      // objects.
102      if(isIndex)
103      {
104          // Get the number of persistent objects allocated
105          UINT32       persistentNum = NvCapGetPersistentNumber();
106
107          // If we have not allocated the requisite number of evict objects, then we
108          // need to reserve space for them.
109          // NOTE: some of this is not written as simply as it might seem because
110          // the values are all unsigned and subtracting needs to be done carefully
111          // so that an underflow doesn't cause problems.
112          if(persistentNum < MIN_EVICT_OBJECTS)
113              reserved += (MIN_EVICT_OBJECTS - persistentNum) * NV_EVICT_OBJECT_SIZE;
114      }
115      // If this is not an index or is not a counter, reserve space for the
116      // required number of counter indexes
117      if(!isIndex || !isCounter)
118      {
119          // Get the number of counters
120          UINT32       counterNum = NvCapGetCounterNumber();
121
122          // If the required number of counters have not been allocated, reserved
123          // space for the extra needed counters
124          if(counterNum < MIN_COUNTER_INDICES)
125              reserved += (MIN_COUNTER_INDICES - counterNum) * NV_INDEX_COUNTER_SIZE;
126      }
127      // Check that the requested allocation will fit after making sure that there
128      // will be no chance of overflow
129      return ((reserved < remainBytes)
130              && (size <= remainBytes)
131              && (size + reserved <= remainBytes));
132  }
```

8.4.3.8 NvWriteNvListEnd()

Function to write the list terminator.

```
133  NV_REF
134  NvWriteNvListEnd(
135      NV_REF            end
```

 Copyright © TCG 2006-2020

```
136     )
137 {
138     // Marker is initialized with zeros
139     BYTE        listEndMarker[sizeof(NV_LIST_TERMINATOR)] = {0};
140     UINT64      maxCount = NvReadMaxCount();
141 //
142     // This is a constant check that can be resolved at compile time.
143     cAssert(sizeof(UINT64) <= sizeof(NV_LIST_TERMINATOR) - sizeof(UINT32));
144
145     // Copy the maxCount value to the marker buffer
146     MemoryCopy(&listEndMarker[sizeof(UINT32)], &maxCount, sizeof(UINT64));
147     pAssert(end + sizeof(NV_LIST_TERMINATOR) <= s_evictNvEnd);
148
149     // Write it to memory
150     NvWrite(end, sizeof(NV_LIST_TERMINATOR), &listEndMarker);
151     return end + sizeof(NV_LIST_TERMINATOR);
152 }
```

8.4.3.9 NvAdd()

This function adds a new entity to NV.

This function requires that there is enough space to add a new entity (i.e., that NvTestSpace() has been called and the available space is at least as large as the required space).

The *totalSize* will be the size of *entity*. If a handle is added, this function will increase the size accordingly.

```
153 static TPM_RC
154 NvAdd(
155     UINT32           totalSize,     // IN: total size needed for this entity For
156                                     //     evict object, totalSize is the same as
157                                     //     bufferSize.  For NV Index, totalSize is
158                                     //     bufferSize plus index data size
159     UINT32           bufferSize,    // IN: size of initial buffer
160     TPM_HANDLE       handle,        // IN: optional handle
161     BYTE            *entity         // IN: initial buffer
162     )
163 {
164     NV_REF          newAddr;        // IN: where the new entity will start
165     NV_REF          nextAddr;
166 //
167     RETURN_IF_NV_IS_NOT_AVAILABLE;
168
169     // Get the end of data list
170     newAddr = NvGetEnd();
171
172     // Step over the forward pointer
173     nextAddr = newAddr + sizeof(UINT32);
174
175     // Optionally write the handle. For indexes, the handle is TPM_RH_UNASSIGNED
176     // so that the handle in the nvIndex is used instead of writing this value
177     if(handle != TPM_RH_UNASSIGNED)
178     {
179         NvWrite((UINT32)nextAddr, sizeof(TPM_HANDLE), &handle);
180         nextAddr += sizeof(TPM_HANDLE);
181     }
182     // Write entity data
183     NvWrite((UINT32)nextAddr, bufferSize, entity);
184
185     // Advance the pointer by the amount of the total
186     nextAddr += totalSize;
187
188     // Finish by writing the link value
189
190     // Write the next offset (relative addressing)
```

```
191         totalSize = nextAddr - newAddr;
192
193         // Write link value
194         NvWrite((UINT32)newAddr, sizeof(UINT32), &totalSize);
195
196         // Write the list terminator
197         NvWriteNvListEnd(nextAddr);
198
199         return TPM_RC_SUCCESS;
200     }
```

8.4.3.10 NvDelete()

This function is used to delete an NV Index or persistent object from NV memory.

```
201     static TPM_RC
202     NvDelete(
203         NV_REF            entityRef       // IN: reference to entity to be deleted
204         )
205     {
206         UINT32           entrySize;
207         // adjust entityAddr to back up and point to the forward pointer
208         NV_REF           entryRef = entityRef - sizeof(UINT32);
209         NV_REF           endRef = NvGetEnd();
210         NV_REF           nextAddr; // address of the next entry
211     //
212         RETURN_IF_NV_IS_NOT_AVAILABLE;
213
214         // Get the offset of the next entry. That is, back up and point to the size
215         // field of the entry
216         NvRead(&entrySize, entryRef, sizeof(UINT32));
217
218         // The next entry after the one being deleted is at a relative offset
219         // from the current entry
220         nextAddr = entryRef + entrySize;
221
222         // If this is not the last entry, move everything up
223         if(nextAddr < endRef)
224         {
225             pAssert(nextAddr > entryRef);
226             _plat__NvMemoryMove(nextAddr,
227                                 entryRef,
228                                 (endRef - nextAddr));
229         }
230         // The end of the used space is now moved up by the amount of space we just
231         // reclaimed
232         endRef -= entrySize;
233
234         // Write the end marker, and make the new end equal to the first byte after
235         // the just added end value. This will automatically update the NV value for
236         // maxCounter.
237         // NOTE: This is the call that sets flag to cause NV to be updated
238         endRef = NvWriteNvListEnd(endRef);
239
240         // Clear the reclaimed memory
241         _plat__NvMemoryClear(endRef, entrySize);
242
243         return TPM_RC_SUCCESS;
244     }
```

8.4.4 RAM-based NV Index Data Access Functions

8.4.4.1 Introduction

The data layout in ram buffer is {size of(NV_handle + attributes + data NV_handle, attributes, data} for each NV Index data stored in RAM.

NV storage associated with orderly data is updated when a NV Index is added but NOT when the data or attributes are changed. Orderly data is only updated to NV on an orderly shutdown (TPM2_Shutdown())

8.4.4.2 NvRamNext()

This function is used to iterate trough the list of Ram Index values. *iter needs to be initialized by calling

```
245 static NV_RAM_REF
246 NvRamNext(
247     NV_RAM_REF      *iter,          // IN/OUT: the list iterator
248     TPM_HANDLE      *handle         // OUT: the handle of the next item.
249     )
250 {
251     NV_RAM_REF           currentAddr;
252     NV_RAM_HEADER        header;
253 //
254     // If iterator is at the beginning of list
255     if(*iter == NV_RAM_REF_INIT)
256     {
257         // Initialize iterator
258         *iter = &s_indexOrderlyRam[0];
259     }
260     // if we are going to return what the iter is currently pointing to...
261     currentAddr = *iter;
262
263     // If iterator reaches the end of NV space, then don't advance and return
264     // that we are at the end of the list. The end of the list occurs when
265     // we don't have space for a size and a handle
266     if(currentAddr + sizeof(NV_RAM_HEADER) > RAM_ORDERLY_END)
267         return NULL;
268     // read the header of the next entry
269     MemoryCopy(&header, currentAddr, sizeof(NV_RAM_HEADER));
270
271     // if the size field is zero, then we have hit the end of the list
272     if(header.size == 0)
273         // leave the *iter pointing at the end of the list
274         return NULL;
275     // advance the header by the size of the entry
276     *iter = currentAddr + header.size;
277
278 //    pAssert(*iter <= RAM_ORDERLY_END);
279     if(handle != NULL)
280         *handle = header.handle;
281     return currentAddr;
282 }
```

8.4.4.3 NvRamGetEnd()

This routine performs the same function as NvGetEnd() but for the RAM data.

```
283 static NV_RAM_REF
284 NvRamGetEnd(
285     void
286     )
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
287 {
288     NV_RAM_REF          iter = NV_RAM_REF_INIT;
289     NV_RAM_REF          currentAddr;
290 //
291     // Scan until the next address is 0
292     while((currentAddr = NvRamNext(&iter, NULL)) != 0);
293     return iter;
294 }
```

8.4.4.4 NvRamTestSpaceIndex()

This function indicates if there is enough RAM space to add a data for a new NV Index.

Return Value	Meaning
TRUE(1)	space available
FALSE(0)	no enough space

```
295 static BOOL
296 NvRamTestSpaceIndex(
297     UINT32            size            // IN: size of the data to be added to RAM
298     )
299 {
300     UINT32           remaining = (UINT32)(RAM_ORDERLY_END - NvRamGetEnd());
301     UINT32           needed = sizeof(NV_RAM_HEADER) + size;
302 //
303     // NvRamGetEnd points to the next available byte.
304     return remaining >= needed;
305 }
```

8.4.4.5 NvRamGetIndex()

This function returns the offset of NV data in the RAM buffer

This function requires that NV Index is in RAM. That is, the index must be known to exist.

```
306 static NV_RAM_REF
307 NvRamGetIndex(
308     TPMI_RH_NV_INDEX      handle          // IN: NV handle
309     )
310 {
311     NV_RAM_REF          iter = NV_RAM_REF_INIT;
312     NV_RAM_REF          currentAddr;
313     TPM_HANDLE          foundHandle;
314 //
315     while((currentAddr = NvRamNext(&iter, &foundHandle)) != 0)
316     {
317         if(handle == foundHandle)
318             break;
319     }
320     return currentAddr;
321 }
```

8.4.4.6 NvUpdateIndexOrderlyData()

This function is used to cause an update of the orderly data to the NV backing store.

```
322 void
323 NvUpdateIndexOrderlyData(
324     void
325     )
```

```
326 {
327     // Write reserved RAM space to NV
328     NvWrite(NV_INDEX_RAM_DATA, sizeof(s_indexOrderlyRam), s_indexOrderlyRam);
329 }
```

8.4.4.7 NvAddRAM()

This function adds a new data area to RAM.

This function requires that enough free RAM space is available to add the new data.

This function should be called after the NV Index space has been updated and the index removed. This insures that NV is available so that checking for NV availability is not required during this function.

```
330 static void
331 NvAddRAM(
332     TPMS_NV_PUBLIC  *index          // IN: the index descriptor
333     )
334 {
335     NV_RAM_HEADER       header;
336     NV_RAM_REF          end = NvRamGetEnd();
337 //
338     header.size = sizeof(NV_RAM_HEADER) + index->dataSize;
339     header.handle = index->nvIndex;
340     MemoryCopy(&header.attributes, &index->attributes, sizeof(TPMA_NV));
341
342     pAssert(ORDERLY_RAM_ADDRESS_OK(end, header.size));
343
344     // Copy the header to the memory
345     MemoryCopy(end, &header, sizeof(NV_RAM_HEADER));
346
347     // Clear the data area (just in case)
348     MemorySet(end + sizeof(NV_RAM_HEADER), 0, index->dataSize);
349
350     // Step over this new entry
351     end += header.size;
352
353     // If the end marker will fit, add it
354     if(end + sizeof(UINT32) < RAM_ORDERLY_END)
355         MemorySet(end, 0, sizeof(UINT32));
356     // Write reserved RAM space to NV to reflect the newly added NV Index
357     SET_NV_UPDATE(UT_ORDERLY);
358
359     return;
360 }
```

8.4.4.8 NvDeleteRAM()

This function is used to delete a RAM-backed NV Index data area. The space used by the entry are overwritten by the contents of the Index data that comes after (the data is moved up to fill the hole left by removing this index. The reclaimed space is cleared to zeros. This function assumes the data of NV Index exists in RAM.

This function should be called after the NV Index space has been updated and the index removed. This insures that NV is available so that checking for NV availability is not required during this function.

```
361 static void
362 NvDeleteRAM(
363     TPMI_RH_NV_INDEX     handle          // IN: NV handle
364     )
365 {
366     NV_RAM_REF           nodeAddress;
367     NV_RAM_REF           nextNode;
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
368     UINT32                size;
369     NV_RAM_REF            lastUsed = NvRamGetEnd();
370 //
371     nodeAddress = NvRamGetIndex(handle);
372
373     pAssert(nodeAddress != 0);
374
375     // Get node size
376     MemoryCopy(&size, nodeAddress, sizeof(size));
377
378     // Get the offset of next node
379     nextNode = nodeAddress + size;
380
381     // Copy the data
382     MemoryCopy(nodeAddress, nextNode, (int)(lastUsed - nextNode));
383
384     // Clear out the reclaimed space
385     MemorySet(lastUsed - size, 0, size);
386
387     // Write reserved RAM space to NV to reflect the newly delete NV Index
388     SET_NV_UPDATE(UT_ORDERLY);
389
390     return;
391 }
```

8.4.4.9 NvReadIndex()

This function is used to read the NV Index NV_INDEX. This is used so that the index information can be compressed and only this function would be needed to decompress it. Mostly, compression would only be able to save the space needed by the policy.

```
392 void
393 NvReadNvIndexInfo(
394     NV_REF           ref,            // IN: points to NV where index is located
395     NV_INDEX        *nvIndex         // OUT: place to receive index data
396     )
397 {
398     pAssert(nvIndex != NULL);
399     NvRead(nvIndex, ref, sizeof(NV_INDEX));
400     return;
401 }
```

8.4.4.10 NvReadObject()

This function is used to read a persistent object. This is used so that the object information can be compressed and only this function would be needed to uncompress it.

```
402 void
403 NvReadObject(
404     NV_REF           ref,            // IN: points to NV where index is located
405     OBJECT          *object          // OUT: place to receive the object data
406     )
407 {
408     NvRead(object, (ref + sizeof(TPM_HANDLE)), sizeof(OBJECT));
409     return;
410 }
```

8.4.4.11 NvFindEvict()

This function will return the NV offset of an evict object

Return Value	Meaning
0	evict object not found
0	offset of evict object

```
411 static NV_REF
412 NvFindEvict(
413     TPM_HANDLE       nvHandle,
414     OBJECT          *object
415     )
416 {
417     NV_REF          found = NvFindHandle(nvHandle);
418 //
419     // If we found the handle and the request included an object pointer, fill it in
420     if(found != 0 && object != NULL)
421         NvReadObject(found, object);
422     return found;
423 }
```

8.4.4.12 NvIndexIsDefined()

See if an index is already defined

```
424 BOOL
425 NvIndexIsDefined(
426     TPM_HANDLE       nvHandle       // IN: Index to look for
427     )
428 {
429     return (NvFindHandle(nvHandle) != 0);
430 }
```

8.4.4.13 NvConditionallyWrite()

Function to check if the data to be written has changed and write it if it has

Error Returns	Meaning
TPM_RC_NV_RATE	NV is unavailable because of rate limit
TPM_RC_NV_UNAVAILABLE	NV is inaccessible

```
431 static TPM_RC
432 NvConditionallyWrite(
433     NV_REF           entryAddr,     // IN: stating address
434     UINT32           size,          // IN: size of the data to write
435     void            *data           // IN: the data to write
436     )
437 {
438     // If the index data is actually changed, then a write to NV is required
439     if(_plat__NvIsDifferent(entryAddr, size, data))
440     {
441         // Write the data if NV is available
442         if(g_NvStatus == TPM_RC_SUCCESS)
443         {
444             NvWrite(entryAddr, size, data);
445         }
446         return g_NvStatus;
447     }
448     return TPM_RC_SUCCESS;
449 }
```

8.4.4.14 NvReadNvIndexAttributes()

This function returns the attributes of an NV Index.

```
450  static TPMA_NV
451  NvReadNvIndexAttributes(
452      NV_REF          locator         // IN: reference to an NV index
453      )
454  {
455      TPMA_NV                 attributes;
456  //
457      NvRead(&attributes,
458             locator + offsetof(NV_INDEX, publicArea.attributes),
459             sizeof(TPMA_NV));
460      return attributes;
461  }
```

8.4.4.15 NvReadRamIndexAttributes()

This function returns the attributes from the RAM header structure. This function is used to deal with the fact that the header structure is only byte aligned.

```
462  static TPMA_NV
463  NvReadRamIndexAttributes(
464      NV_RAM_REF      ref             // IN: pointer to a NV_RAM_HEADER
465      )
466  {
467      TPMA_NV         attributes;
468  //
469      MemoryCopy(&attributes, ref + offsetof(NV_RAM_HEADER, attributes),
470                 sizeof(TPMA_NV));
471      return attributes;
472  }
```

8.4.4.16 NvWriteNvIndexAttributes()

This function is used to write just the attributes of an index to NV.

Error Returns	Meaning
TPM_RC_NV_RATE	NV is rate limiting so retry
TPM_RC_NV_UNAVAILABLE	NV is not available

```
473  static TPM_RC
474  NvWriteNvIndexAttributes(
475      NV_REF          locator,        // IN: location of the index
476      TPMA_NV         attributes      // IN: attributes to write
477      )
478  {
479      return NvConditionallyWrite(
480          locator + offsetof(NV_INDEX, publicArea.attributes),
481          sizeof(TPMA_NV),
482          &attributes);
483  }
```

8.4.4.17 NvWriteRamIndexAttributes()

This function is used to write the index attributes into an unaligned structure

```
484 static void
485 NvWriteRamIndexAttributes(
486     NV_RAM_REF      ref,          // IN: address of the header
487     TPMA_NV         attributes    // IN: the attributes to write
488     )
489 {
490     MemoryCopy(ref + offsetof(NV_RAM_HEADER, attributes), &attributes,
491                sizeof(TPMA_NV));
492     return;
493 }
```

8.4.5 Externally Accessible Functions

8.4.5.1 NvIsPlatformPersistentHandle()

This function indicates if a handle references a persistent object in the range belonging to the platform.

Return Value	Meaning
TRUE(1)	handle references a platform persistent object and may reference an owner persistent object either
FALSE(0)	handle does not reference platform persistent object

```
494 BOOL
495 NvIsPlatformPersistentHandle(
496     TPM_HANDLE      handle        // IN: handle
497     )
498 {
499     return (handle >= PLATFORM_PERSISTENT && handle <= PERSISTENT_LAST);
500 }
```

8.4.5.2 NvIsOwnerPersistentHandle()

This function indicates if a handle references a persistent object in the range belonging to the owner.

Return Value	Meaning
TRUE(1)	handle is owner persistent handle
FALSE(0)	handle is not owner persistent handle and may not be a persistent handle at all

```
501 BOOL
502 NvIsOwnerPersistentHandle(
503     TPM_HANDLE      handle        // IN: handle
504     )
505 {
506     return (handle >= PERSISTENT_FIRST && handle < PLATFORM_PERSISTENT);
507 }
```

8.4.5.3 NvIndexIsAccessible()

This function validates that a handle references a defined NV Index and that the Index is currently accessible.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

Error Returns	Meaning
TPM_RC_HANDLE	the handle points to an undefined NV Index If *shEnable* is CLEAR, this would include an index created using *ownerAuth*. If *phEnableNV* is CLEAR, this would include and index created using *platformAuth*
TPM_RC_NV_READLOCKED	Index is present but locked for reading and command does not write to the index
TPM_RC_NV_WRITELOCKED	Index is present but locked for writing and command writes to the index

```
508 TPM_RC
509 NvIndexIsAccessible(
510     TPMI_RH_NV_INDEX     handle         // IN: handle
511     )
512 {
513     NV_INDEX             *nvIndex = NvGetIndexInfo(handle, NULL);
514 //
515     if(nvIndex == NULL)
516     // If index is not found, return TPM_RC_HANDLE
517         return TPM_RC_HANDLE;
518     if(gc.shEnable == FALSE || gc.phEnableNV == FALSE)
519     {
520         // if shEnable is CLEAR, an ownerCreate NV Index should not be
521         // indicated as present
522         if(!IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, PLATFORMCREATE))
523         {
524             if(gc.shEnable == FALSE)
525                 return TPM_RC_HANDLE;
526         }
527         // if phEnableNV is CLEAR, a platform created Index should not
528         // be visible
529         else if(gc.phEnableNV == FALSE)
530             return TPM_RC_HANDLE;
531     }
532 #if 0 // Writelock test for debug
533     // If the Index is write locked and this is an NV Write operation...
534     if(IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, WRITELOCKED)
535        &&  IsWriteOperation(commandIndex))
536     {
537         // then return a locked indication unless the command is TPM2_NV_WriteLock
538         if(GetCommandCode(commandIndex) != TPM_CC_NV_WriteLock)
539             return TPM_RC_NV_LOCKED;
540         return TPM_RC_SUCCESS;
541     }
542 #endif
543 #if 0   // Readlock Test for debug
544     // If the Index is read locked and this is an NV Read operation...
545     if(IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, READLOCKED)
546        && IsReadOperation(commandIndex))
547     {
548         // then return a locked indication unless the command is TPM2_NV_ReadLock
549         if(GetCommandCode(commandIndex) != TPM_CC_NV_ReadLock)
550             return TPM_RC_NV_LOCKED;
551     }
552 #endif
553     // NV Index is accessible
554     return TPM_RC_SUCCESS;
555 }
```

8.4.5.4 NvGetEvictObject()

This function is used to dereference an evict object handle and get a pointer to the object.

 Copyright © TCG 2006-2020

Error Returns	Meaning
TPM_RC_HANDLE	the handle does not point to an existing persistent object

```
556  TPM_RC
557  NvGetEvictObject(
558      TPM_HANDLE        handle,        // IN: handle
559      OBJECT           *object         // OUT: object data
560      )
561  {
562      NV_REF           entityAddr;         // offset points to the entity
563  //
564      // Find the address of evict object and copy to object
565      entityAddr = NvFindEvict(handle, object);
566
567      // whether there is an error or not, make sure that the evict
568      // status of the object is set so that the slot will get freed on exit
569      // Must do this after NvFindEvict loads the object
570      object->attributes.evict = SET;
571
572      // If handle is not found, return an error
573      if(entityAddr == 0)
574          return TPM_RC_HANDLE;
575      return TPM_RC_SUCCESS;
576  }
```

8.4.5.5 NvIndexCacheInit()

Function to initialize the Index cache

```
577  void
578  NvIndexCacheInit(
579      void
580      )
581  {
582      s_cachedNvRef = NV_REF_INIT;
583      s_cachedNvRamRef = NV_RAM_REF_INIT;
584      s_cachedNvIndex.publicArea.nvIndex = TPM_RH_UNASSIGNED;
585      return;
586  }
```

8.4.5.6 NvGetIndexData()

This function is used to access the data in an NV Index. The data is returned as a byte sequence.

This function requires that the NV Index be defined, and that the required data is within the data range. It also requires that TPMA_NV_WRITTEN of the Index is SET.

```
587  void
588  NvGetIndexData(
589      NV_INDEX             *nvIndex,       // IN: the in RAM index descriptor
590      NV_REF                locator,       // IN: where the data is located
591      UINT32                offset,        // IN: offset of NV data
592      UINT16                size,          // IN: number of octets of NV data to read
593      void                 *data           // OUT: data buffer
594      )
595  {
596      TPMA_NV              nvAttributes;
597  //
598      pAssert(nvIndex != NULL);
599
600      nvAttributes = nvIndex->publicArea.attributes;
```

```
601
602     pAssert(IS_ATTRIBUTE(nvAttributes, TPMA_NV, WRITTEN));
603
604     if(IS_ATTRIBUTE(nvAttributes, TPMA_NV, ORDERLY))
605     {
606         // Get data from RAM buffer
607         NV_RAM_REF          ramAddr = NvRamGetIndex(nvIndex->publicArea.nvIndex);
608         pAssert(ramAddr != 0 && (size <=
609                 ((NV_RAM_HEADER *)ramAddr)->size - sizeof(NV_RAM_HEADER) - offset));
610         MemoryCopy(data, ramAddr + sizeof(NV_RAM_HEADER) + offset, size);
611     }
612     else
613     {
614         // Validate that read falls within range of the index
615         pAssert(offset <= nvIndex->publicArea.dataSize
616                 &&  size <= (nvIndex->publicArea.dataSize - offset));
617         NvRead(data, locator + sizeof(NV_INDEX) + offset, size);
618     }
619     return;
620 }
```

8.4.5.7 NvHashIndexData()

This function adds Index data to a hash. It does this in parts to avoid large stack buffers.

```
621 void
622 NvHashIndexData(
623     HASH_STATE          *hashState,      // IN: Initialized hash state
624     NV_INDEX            *nvIndex,        // IN: Index
625     NV_REF               locator,        // IN: where the data is located
626     UINT32               offset,         // IN: starting offset
627     UINT16               size            // IN: amount to hash
628 )
629 {
630 #define BUFFER_SIZE     64
631     BYTE                 buffer[BUFFER_SIZE];
632     if (offset > nvIndex->publicArea.dataSize)
633         return;
634     // Make sure that we don't try to read off the end.
635     if ((offset + size) > nvIndex->publicArea.dataSize)
636         size = nvIndex->publicArea.dataSize - (UINT16)offset;
637 #if BUFFER_SIZE >= MAX_NV_INDEX_SIZE
638     NvGetIndexData(nvIndex, locator, offset, size, buffer);
639     CryptDigestUpdate(hashState, size, buffer);
640 #else
641     {
642         INT16               i;
643         UINT16              readSize;
644         //
645         for (i = size; i > 0; offset += readSize, i -= readSize)
646         {
647             readSize = (i < BUFFER_SIZE) ? i : BUFFER_SIZE;
648             NvGetIndexData(nvIndex, locator, offset, readSize, buffer);
649             CryptDigestUpdate(hashState, readSize, buffer);
650         }
651     }
652 #endif // BUFFER_SIZE >= MAX_NV_INDEX_SIZE
653 #undef  BUFFER_SIZE
654 }
```

8.4.5.8 NvGetUINT64Data()

Get data in integer format of a bit or counter NV Index.

This function requires that the NV Index is defined and that the NV Index previously has been written.

```
655 UINT64
656 NvGetUINT64Data(
657     NV_INDEX            *nvIndex,       // IN: the in RAM index descriptor
658     NV_REF               locator        // IN: where index exists in NV
659     )
660 {
661     UINT64                intVal;
662 //
663     // Read the value and convert it to internal format
664     NvGetIndexData(nvIndex, locator, 0, 8, &intVal);
665     return BYTE_ARRAY_TO_UINT64(((BYTE *)&intVal));
666 }
```

8.4.5.9 NvWriteIndexAttributes()

This function is used to write just the attributes of an index.

Error Returns	Meaning
TPM_RC_NV_RATE	NV is rate limiting so retry
TPM_RC_NV_UNAVAILABLE	NV is not available

```
667 TPM_RC
668 NvWriteIndexAttributes(
669     TPM_HANDLE       handle,
670     NV_REF           locator,       // IN: location of the index
671     TPMA_NV          attributes     // IN: attributes to write
672     )
673 {
674     TPM_RC              result;
675 //
676     if(IS_ATTRIBUTE(attributes, TPMA_NV, ORDERLY))
677     {
678         NV_RAM_REF      ram = NvRamGetIndex(handle);
679         NvWriteRamIndexAttributes(ram, attributes);
680         result = TPM_RC_SUCCESS;
681     }
682     else
683     {
684         result = NvWriteNvIndexAttributes(locator, attributes);
685     }
686     return result;
687 }
```

8.4.5.10 NvWriteIndexAuth()

This function is used to write the *authValue* of an index. It is used by TPM2_NV_ChangeAuth()

Error Returns	Meaning
TPM_RC_NV_RATE	NV is rate limiting so retry
TPM_RC_NV_UNAVAILABLE	NV is not available

```
688 TPM_RC
689 NvWriteIndexAuth(
690     NV_REF           locator,       // IN: location of the index
691     TPM2B_AUTH      *authValue      // IN: the authValue to write
692     )
```

 Copyright © TCG 2006-2020

```
693  {
694      TPM_RC              result;
695  //
696      // If the locator is pointing to the cached index value...
697      if(locator == s_cachedNvRef)
698      {
699          // copy the authValue to the cached index so it will be there if we
700          // look for it. This is a safety thing.
701          MemoryCopy2B(&s_cachedNvIndex.authValue.b, &authValue->b,
702                       sizeof(s_cachedNvIndex.authValue.t.buffer));
703      }
704      result = NvConditionallyWrite(
705          locator + offsetof(NV_INDEX, authValue),
706          sizeof(UINT16) + authValue->t.size,
707          authValue);
708      return result;
709  }
```

8.4.5.11 NvGetIndexInfo()

This function loads the *nvIndex* Info into the NV cache and returns a pointer to the NV_INDEX. If the returned value is zero, the index was not found. The *locator* parameter, if not NULL, will be set to the offset in NV of the Index (the location of the handle of the Index).

This function will set the index cache. If the index is orderly, the attributes from RAM are substituted for the attributes in the cached index

```
710  NV_INDEX *
711  NvGetIndexInfo(
712      TPM_HANDLE       nvHandle,      // IN: the index handle
713      NV_REF          *locator        // OUT: location of the index
714      )
715  {
716      if(s_cachedNvIndex.publicArea.nvIndex != nvHandle)
717      {
718          s_cachedNvIndex.publicArea.nvIndex = TPM_RH_UNASSIGNED;
719          s_cachedNvRamRef = 0;
720          s_cachedNvRef = NvFindHandle(nvHandle);
721          if(s_cachedNvRef == 0)
722              return NULL;
723          NvReadNvIndexInfo(s_cachedNvRef, &s_cachedNvIndex);
724          if(IS_ATTRIBUTE(s_cachedNvIndex.publicArea.attributes, TPMA_NV, ORDERLY))
725          {
726              s_cachedNvRamRef = NvRamGetIndex(nvHandle);
727              s_cachedNvIndex.publicArea.attributes =
728                  NvReadRamIndexAttributes(s_cachedNvRamRef);
729          }
730      }
731      if(locator != NULL)
732          *locator = s_cachedNvRef;
733      return &s_cachedNvIndex;
734  }
```

8.4.5.12 NvWriteIndexData()

This function is used to write NV index data. It is intended to be used to update the data associated with the default index.

This function requires that the NV Index is defined, and the data is within the defined data range for the index.

Index data is only written due to a command that modifies the data in a single index. There is no case where changes are made to multiple indexes data at the same time. Multiple attributes may be change

but not multiple index data. This is important because we will normally be handling the index for which we have the cached pointer values.

Error Returns	Meaning
TPM_RC_NV_RATE	NV is rate limiting so retry
TPM_RC_NV_UNAVAILABLE	NV is not available

```
735 TPM_RC
736 NvWriteIndexData(
737     NV_INDEX        *nvIndex,       // IN: the description of the index
738     UINT32           offset,        // IN: offset of NV data
739     UINT32           size,          // IN: size of NV data
740     void            *data           // IN: data buffer
741     )
742 {
743     TPM_RC                result = TPM_RC_SUCCESS;
744 //
745     pAssert(nvIndex != NULL);
746     // Make sure that this is dealing with the 'default' index.
747     // Note: it is tempting to change the calling sequence so that the 'default' is
748     // presumed.
749     pAssert(nvIndex->publicArea.nvIndex == s_cachedNvIndex.publicArea.nvIndex);
750
751     // Validate that write falls within range of the index
752     pAssert(offset <= nvIndex->publicArea.dataSize
753             &&  size <= (nvIndex->publicArea.dataSize - offset));
754
755     // Update TPMA_NV_WRITTEN bit if necessary
756     if(!IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, WRITTEN))
757     {
758         // Update the in memory version of the attributes
759         SET_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, WRITTEN);
760
761         // If this is not orderly, then update the NV version of
762         // the attributes
763         if(!IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, ORDERLY))
764         {
765             result = NvWriteNvIndexAttributes(s_cachedNvRef,
766                                               nvIndex->publicArea.attributes);
767             if(result != TPM_RC_SUCCESS)
768                 return result;
769             // If this is a partial write of an ordinary index, clear the whole
770             // index.
771             if(IsNvOrdinaryIndex(nvIndex->publicArea.attributes)
772                && (nvIndex->publicArea.dataSize > size))
773                 _plat__NvMemoryClear(s_cachedNvRef + sizeof(NV_INDEX),
774                                      nvIndex->publicArea.dataSize);
775         }
776         else
777         {
778             // This is orderly so update the RAM version
779             MemoryCopy(s_cachedNvRamRef + offsetof(NV_RAM_HEADER, attributes),
780                        &nvIndex->publicArea.attributes, sizeof(TPMA_NV));
781             // If setting WRITTEN for an orderly counter, make sure that the
782             // state saved version of the counter is saved
783             if(IsNvCounterIndex(nvIndex->publicArea.attributes))
784                 SET_NV_UPDATE(UT_ORDERLY);
785             // If setting the written attribute on an ordinary index, make sure that
786             // the data is all cleared out in case there is a partial write. This
787             // is only necessary for ordinary indexes because all of the other types
788             // are always written in total.
789             else if(IsNvOrdinaryIndex(nvIndex->publicArea.attributes))
790                 MemorySet(s_cachedNvRamRef + sizeof(NV_RAM_HEADER),

```
791                             0, nvIndex->publicArea.dataSize);
792             }
793         }
794         // If this is orderly data, write it to RAM
795         if(IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, ORDERLY))
796         {
797             // Note: if this is the first write to a counter, the code above will queue
798             // the write to NV of the RAM data in order to update TPMA_NV_WRITTEN. In
799             // process of doing that write, it will also write the initial counter value
800
801             // Update RAM
802             MemoryCopy(s_cachedNvRamRef + sizeof(NV_RAM_HEADER) + offset, data, size);
803
804             // And indicate that the TPM is no longer orderly
805             g_clearOrderly = TRUE;
806         }
807         else
808         {
809             // Offset into the index to the first byte of the data to be written to NV
810             result = NvConditionallyWrite(s_cachedNvRef + sizeof(NV_INDEX) + offset,
811                                           size, data);
812         }
813         return result;
814     }
```

8.4.5.13 NvWriteUINT64Data()

This function to write back a UINT64 value. The various UINT64 values (bits, counters, and PINs) are kept in canonical format but manipulate in native format. This takes a native format value converts it and saves it back as in canonical format.

This function will return the value from NV or RAM depending on the type of the index (orderly or not)

```
815     TPM_RC
816     NvWriteUINT64Data(
817         NV_INDEX        *nvIndex,       // IN: the description of the index
818         UINT64           intValue       // IN: the value to write
819         )
820     {
821         BYTE            bytes[8];
822         UINT64_TO_BYTE_ARRAY(intValue, bytes);
823     //
824         return NvWriteIndexData(nvIndex, 0, 8, &bytes);
825     }
```

8.4.5.14 NvGetIndexName()

This function computes the Name of an index The *name* buffer receives the bytes of the Name and the return value is the number of octets in the Name.

This function requires that the NV Index is defined.

```
826     TPM2B_NAME *
827     NvGetIndexName(
828         NV_INDEX        *nvIndex,       // IN: the index over which the name is to be
829                                         //     computed
830         TPM2B_NAME      *name           // OUT: name of the index
831         )
832     {
833         UINT16              dataSize, digestSize;
834         BYTE                marshalBuffer[sizeof(TPMS_NV_PUBLIC)];
835         BYTE               *buffer;
836         HASH_STATE          hashState;
```

```
837 //
838     // Marshal public area
839     buffer = marshalBuffer;
840     dataSize = TPMS_NV_PUBLIC_Marshal(&nvIndex->publicArea, &buffer, NULL);
841
842     // hash public area
843     digestSize = CryptHashStart(&hashState, nvIndex->publicArea.nameAlg);
844     CryptDigestUpdate(&hashState, dataSize, marshalBuffer);
845
846     // Complete digest leaving room for the nameAlg
847     CryptHashEnd(&hashState, digestSize, &name->b.buffer[2]);
848
849     // Include the nameAlg
850     UINT16_TO_BYTE_ARRAY(nvIndex->publicArea.nameAlg, name->b.buffer);
851     name->t.size = digestSize + 2;
852     return name;
853 }
```

8.4.5.15 NvGetNameByIndexHandle()

This function is used to compute the Name of an NV Index referenced by handle.

The *name* buffer receives the bytes of the Name and the return value is the number of octets in the Name.

This function requires that the NV Index is defined.

```
854 TPM2B_NAME *
855 NvGetNameByIndexHandle(
856     TPMI_RH_NV_INDEX     handle,         // IN: handle of the index
857     TPM2B_NAME          *name            // OUT: name of the index
858     )
859 {
860     NV_INDEX             *nvIndex = NvGetIndexInfo(handle, NULL);
861 //
862     return NvGetIndexName(nvIndex, name);
863 }
```

8.4.5.16 NvDefineIndex()

This function is used to assign NV memory to an NV Index.

Error Returns	Meaning
TPM_RC_NV_SPACE	insufficient NV space

```
864 TPM_RC
865 NvDefineIndex(
866     TPMS_NV_PUBLIC  *publicArea,    // IN: A template for an area to create.
867     TPM2B_AUTH      *authValue      // IN: The initial authorization value
868     )
869 {
870     // The buffer to be written to NV memory
871     NV_INDEX        nvIndex;            // the index data
872     UINT16          entrySize;          // size of entry
873     TPM_RC          result;
874 //
875     entrySize = sizeof(NV_INDEX);
876
877     // only allocate data space for indexes that are going to be written to NV.
878     // Orderly indexes don't need space.
879     if(!IS_ATTRIBUTE(publicArea->attributes, TPMA_NV, ORDERLY))
880         entrySize += publicArea->dataSize;
```

```
881     // Check if we have enough space to create the NV Index
882     // In this implementation, the only resource limitation is the available NV
883     // space (and possibly RAM space.)  Other implementation may have other
884     // limitation on counter or on NV slots
885     if(!NvTestSpace(entrySize, TRUE, IsNvCounterIndex(publicArea->attributes)))
886         return TPM_RC_NV_SPACE;
887
888     // if the index to be defined is RAM backed, check RAM space availability
889     // as well
890     if(IS_ATTRIBUTE(publicArea->attributes, TPMA_NV, ORDERLY)
891        &&  !NvRamTestSpaceIndex(publicArea->dataSize))
892         return TPM_RC_NV_SPACE;
893     // Copy input value to nvBuffer
894     nvIndex.publicArea = *publicArea;
895
896     // Copy the authValue
897     nvIndex.authValue = *authValue;
898
899     // Add index to NV memory
900     result = NvAdd(entrySize, sizeof(NV_INDEX), TPM_RH_UNASSIGNED,
901                    (BYTE *)&nvIndex);
902     if(result == TPM_RC_SUCCESS)
903     {
904     // If the data of NV Index is RAM backed, add the data area in RAM as well
905         if(IS_ATTRIBUTE(publicArea->attributes, TPMA_NV, ORDERLY))
906             NvAddRAM(publicArea);
907     }
908     return result;
909 }
```

8.4.5.17 NvAddEvictObject()

This function is used to assign NV memory to a persistent object.

Error Returns	Meaning
TPM_RC_NV_HANDLE	the requested handle is already in use
TPM_RC_NV_SPACE	insufficient NV space

```
910 TPM_RC
911 NvAddEvictObject(
912     TPMI_DH_OBJECT    evictHandle,    // IN: new evict handle
913     OBJECT           *object          // IN: object to be added
914     )
915 {
916     TPM_HANDLE        temp = object->evictHandle;
917     TPM_RC            result;
918 //
919     // Check if we have enough space to add the evict object
920     // An evict object needs 8 bytes in index table + sizeof OBJECT
921     // In this implementation, the only resource limitation is the available NV
922     // space.  Other implementation may have other limitation on evict object
923     // handle space
924     if(!NvTestSpace(sizeof(OBJECT) + sizeof(TPM_HANDLE), FALSE, FALSE))
925         return TPM_RC_NV_SPACE;
926
927     // Set evict attribute and handle
928     object->attributes.evict = SET;
929     object->evictHandle = evictHandle;
930
931     // Now put this in NV
932     result = NvAdd(sizeof(OBJECT), sizeof(OBJECT), evictHandle, (BYTE *)object);
933
```

```
934         // Put things back the way they were
935         object->attributes.evict = CLEAR;
936         object->evictHandle = temp;
937
938         return result;
939     }
```

8.4.5.18 NvDeleteIndex()

This function is used to delete an NV Index.

Error Returns	Meaning
TPM_RC_NV_UNAVAILABLE	NV is not accessible
TPM_RC_NV_RATE	NV is rate limiting

```
940     TPM_RC
941     NvDeleteIndex(
942         NV_INDEX        *nvIndex,       // IN: an in RAM index descriptor
943         NV_REF           entityAddr     // IN: location in NV
944         )
945     {
946         TPM_RC           result;
947     //
948         if(nvIndex != NULL)
949         {
950             // Whenever a counter is deleted, make sure that the MaxCounter value is
951             // updated to reflect the value
952             if(IsNvCounterIndex(nvIndex->publicArea.attributes)
953                && IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, WRITTEN))
954                 NvUpdateMaxCount(NvGetUINT64Data(nvIndex, entityAddr));
955             result = NvDelete(entityAddr);
956             if(result != TPM_RC_SUCCESS)
957                 return result;
958             // If the NV Index is RAM backed, delete the RAM data as well
959             if(IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV, ORDERLY))
960                 NvDeleteRAM(nvIndex->publicArea.nvIndex);
961             NvIndexCacheInit();
962         }
963         return TPM_RC_SUCCESS;
964     }
```

8.4.5.19 NvDeleteEvict()

This function will delete a NV evict object. Will return success if object deleted or if it does not exist

```
965     TPM_RC
966     NvDeleteEvict(
967         TPM_HANDLE       handle         // IN: handle of entity to be deleted
968         )
969     {
970         NV_REF      entityAddr = NvFindEvict(handle, NULL);     // pointer to entity
971         TPM_RC      result = TPM_RC_SUCCESS;
972     //
973         if(entityAddr != 0)
974             result = NvDelete(entityAddr);
975         return result;
976     }
```

8.4.5.20 NvFlushHierarchy()

This function will delete persistent objects belonging to the indicated hierarchy. If the storage hierarchy is selected, the function will also delete any NV Index defined using *ownerAuth*.

Error Returns	Meaning
TPM_RC_NV_RATE	NV is unavailable because of rate limit
TPM_RC_NV_UNAVAILABLE	NV is inaccessible

```
977   TPM_RC
978   NvFlushHierarchy(
979       TPMI_RH_HIERARCHY    hierarchy      // IN: hierarchy to be flushed.
980       )
981   {
982       NV_REF           iter = NV_REF_INIT;
983       NV_REF           currentAddr;
984       TPM_HANDLE       entityHandle;
985       TPM_RC           result = TPM_RC_SUCCESS;
986   //
987       while((currentAddr = NvNext(&iter, &entityHandle)) != 0)
988       {
989           if(HandleGetType(entityHandle) == TPM_HT_NV_INDEX)
990           {
991               NV_INDEX        nvIndex;
992   //
993               // If flush endorsement or platform hierarchy, no NV Index would be
994               // flushed
995               if(hierarchy == TPM_RH_ENDORSEMENT || hierarchy == TPM_RH_PLATFORM)
996                   continue;
997               // Get the index information
998               NvReadNvIndexInfo(currentAddr, &nvIndex);
999
1000              // For storage hierarchy, flush OwnerCreated index
1001              if(!IS_ATTRIBUTE(nvIndex.publicArea.attributes, TPMA_NV,
1002                               PLATFORMCREATE))
1003              {
1004                  // Delete the index (including RAM for orderly)
1005                  result = NvDeleteIndex(&nvIndex, currentAddr);
1006                  if(result != TPM_RC_SUCCESS)
1007                      break;
1008                  // Re-iterate from beginning after a delete
1009                  iter = NV_REF_INIT;
1010              }
1011          }
1012          else if(HandleGetType(entityHandle) == TPM_HT_PERSISTENT)
1013          {

1040    return result;
1041 }
```

8.4.5.21 NvSetGlobalLock()

This function is used to SET the TPMA_NV_WRITELOCKED attribute for all NV indexes that have TPMA_NV_GLOBALLOCK SET. This function is use by TPM2_NV_GlobalWriteLock().

Error Returns	Meaning
TPM_RC_NV_RATE	NV is unavailable because of rate limit
TPM_RC_NV_UNAVAILABLE	NV is inaccessible

```
1042 TPM_RC
1043 NvSetGlobalLock(
1044     void
1045     )
1046 {
1047     NV_REF              iter = NV_REF_INIT;
1048     NV_RAM_REF          ramIter = NV_RAM_REF_INIT;
1049     NV_REF              currentAddr;
1050     NV_RAM_REF          currentRamAddr;
1051     TPM_RC              result = TPM_RC_SUCCESS;
1052 //
1053     // Check all normal indexes
1054     while((currentAddr = NvNextIndex(NULL, &iter)) != 0)
1055     {
1056         TPMA_NV         attributes = NvReadNvIndexAttributes(currentAddr);
1057 //

1059         if(!IS_ATTRIBUTE(attributes, TPMA_NV, ORDERLY)
1060            &&  IS_ATTRIBUTE(attributes, TPMA_NV, GLOBALLOCK))
1061         {
1062             SET_ATTRIBUTE(attributes, TPMA_NV, WRITELOCKED);
1063             result = NvWriteNvIndexAttributes(currentAddr, attributes);
1064             if(result != TPM_RC_SUCCESS)
1065                 return result;
1066         }
1067     }
1068     // Now search all the orderly attributes
1069     while((currentRamAddr = NvRamNext(&ramIter, NULL)) != 0)
1070     {
1071         // See if it should be locked
1072         TPMA_NV         attributes = NvReadRamIndexAttributes(currentRamAddr);
1073         if(IS_ATTRIBUTE(attributes, TPMA_NV, GLOBALLOCK))
1074         {
1075             SET_ATTRIBUTE(attributes, TPMA_NV, WRITELOCKED);
1076             NvWriteRamIndexAttributes(currentRamAddr, attributes);
1077         }
1078     }
1079     return result;
1080 }
```

8.4.5.22 InsertSort()

Sort a handle into handle list in ascending order. The total handle number in the list should not exceed MAX_CAP_HANDLES

```
1081 static void
1082 InsertSort(
1083     TPML_HANDLE     *handleList,    // IN/OUT: sorted handle list
1084     UINT32           count,         // IN: maximum count in the handle list
1085     TPM_HANDLE       entityHandle   // IN: handle to be inserted
1086     )
1087 {
1088     UINT32          i, j;
1089     UINT32          originalCount;
1090 //
1091     // For a corner case that the maximum count is 0, do nothing
1092     if(count == 0)
1093         return;
1094     // For empty list, add the handle at the beginning and return
1095     if(handleList->count == 0)
1096     {
1097         handleList->handle[0] = entityHandle;
1098         handleList->count++;
1099         return;
1100     }
1101     // Check if the maximum of the list has been reached
1102     originalCount = handleList->count;
1103     if(originalCount < count)
1104         handleList->count++;
1105     // Insert the handle to the list
1106     for(i = 0; i < originalCount; i++)
1107     {
1108         if(handleList->handle[i] > entityHandle)
1109         {
1110             for(j = handleList->count - 1; j > i; j--)
1111             {
1112                 handleList->handle[j] = handleList->handle[j - 1];
1113             }
1114             break;
1115         }
1116     }
1117     // If a slot was found, insert the handle in this position
1118     if(i < originalCount || handleList->count > originalCount)
1119         handleList->handle[i] = entityHandle;
1120     return;
1121 }
```

8.4.5.23 NvCapGetPersistent()

This function is used to get a list of handles of the persistent objects, starting at *handle*.

Handle must be in valid persistent object handle range, but does not have to reference an existing persistent object.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
1122 TPMI_YES_NO
1123 NvCapGetPersistent(
1124     TPMI_DH_OBJECT   handle,        // IN: start handle
1125     UINT32           count,         // IN: maximum number of returned handles
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
1126        TPML_HANDLE      *handleList      // OUT: list of handle
1127        )
1128    {
1129        TPMI_YES_NO                 more = NO;

1131        NV_REF                      currentAddr;
1132        TPM_HANDLE                  entityHandle;
1133    //
1134        pAssert(HandleGetType(handle) == TPM_HT_PERSISTENT);
1135
1136        // Initialize output handle list
1137        handleList->count = 0;
1138
1139        // The maximum count of handles we may return is MAX_CAP_HANDLES
1140        if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
1141
1142        while((currentAddr = NvNextEvict(&entityHandle, &iter)) != 0)
1143        {
1144            // Ignore persistent handles that have values less than the input handle
1145            if(entityHandle < handle)
1146                continue;
1147            // if the handles in the list have reached the requested count, and there
1148            // are still handles need to be inserted, indicate that there are more.
1149            if(handleList->count == count)
1150                more = YES;
1151            // A handle with a value larger than start handle is a candidate
1152            // for return. Insert sort it to the return list.  Insert sort algorithm
1153            // is chosen here for simplicity based on the assumption that the total
1154            // number of NV indexes is small.  For an implementation that may allow
1155            // large number of NV indexes, a more efficient sorting algorithm may be
1156            // used here.
1157            InsertSort(handleList, count, entityHandle);
1158        }
1159        return more;
1160    }
```

8.4.5.24 NvCapGetIndex()

This function returns a list of handles of NV indexes, starting from *handle*. *Handle* must be in the range of NV indexes, but does not have to reference an existing NV Index.

Return Value	Meaning
YES	if there are more handles to report
NO	all the available handles has been reported

```
1161    TPMI_YES_NO
1162    NvCapGetIndex(
1163        TPMI_DH_OBJECT    handle,         // IN: start handle
1164        UINT32            count,          // IN: max number of returned handles
1165        TPML_HANDLE      *handleList      // OUT: list of handle
1166        )
1167    {
1168        TPMI_YES_NO                 more = NO;
1169        NV_REF                      iter = NV_REF_INIT;
1170        NV_REF                      currentAddr;
1171        TPM_HANDLE                  nvHandle;
1172    //
1173        pAssert(HandleGetType(handle) == TPM_HT_NV_INDEX);
1174
1175        // Initialize output handle list
1176        handleList->count = 0;
1177
```

 Copyright © TCG 2006-2020

```
1178        // The maximum count of handles we may return is MAX_CAP_HANDLES
1179        if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
1180
1181        while((currentAddr = NvNextIndex(&nvHandle, &iter)) != 0)
1182        {
1183            // Ignore index handles that have values less than the 'handle'
1184            if(nvHandle < handle)
1185                continue;
1186            // if the count of handles in the list has reached the requested count,
1187            // and there are still handles to report, set more.
1188            if(handleList->count == count)
1189                more = YES;
1190            // A handle with a value larger than start handle is a candidate
1191            // for return. Insert sort it to the return list.  Insert sort algorithm
1192            // is chosen here for simplicity based on the assumption that the total
1193            // number of NV indexes is small.  For an implementation that may allow
1194            // large number of NV indexes, a more efficient sorting algorithm may be
1195            // used here.
1196            InsertSort(handleList, count, nvHandle);
1197        }
1198        return more;
1199    }
```

8.4.5.25 NvCapGetIndexNumber()

This function returns the count of NV Indexes currently defined.

```
1200    UINT32
1201    NvCapGetIndexNumber(
1202        void
1203        )
1204    {
1205        UINT32           num = 0;
1206        NV_REF           iter = NV_REF_INIT;
1207    //
1208        while(NvNextIndex(NULL, &iter) != 0)
1209            num++;
1210        return num;
1211    }
```

8.4.5.26 NvCapGetPersistentNumber()

Function returns the count of persistent objects currently in NV memory.

```
1212    UINT32
1213    NvCapGetPersistentNumber(
1214        void
1215        )
1216    {
1217        UINT32          num = 0;
1218        NV_REF         iter = NV_REF_INIT;
1219        TPM_HANDLE      handle;
1220    //
1221        while(NvNextEvict(&handle, &iter) != 0)
1222            num++;
1223        return num;
1224    }
```

8.4.5.27 NvCapGetPersistentAvail()

This function returns an estimate of the number of additional persistent objects that could be loaded into NV memory.

```
1225  UINT32
1226  NvCapGetPersistentAvail(
1227      void
1228      )
1229  {
1230      UINT32          availNVSpace;
1231      UINT32          counterNum = NvCapGetCounterNumber();
1232      UINT32          reserved = sizeof(NV_LIST_TERMINATOR);
1233  //
1234      // Get the available space in NV storage
1235      availNVSpace = NvGetFreeBytes();
1236
1237      if(counterNum < MIN_COUNTER_INDICES)
1238      {
1239          // Some space has to be reserved for counter objects.
1240          reserved += (MIN_COUNTER_INDICES - counterNum) * NV_INDEX_COUNTER_SIZE;
1241          if(reserved > availNVSpace)
1242              availNVSpace = 0;
1243          else
1244              availNVSpace -= reserved;
1245      }
1246      return availNVSpace / NV_EVICT_OBJECT_SIZE;
1247  }
```

8.4.5.28 NvCapGetCounterNumber()

Get the number of defined NV Indexes that are counter indexes.

```
1248  UINT32
1249  NvCapGetCounterNumber(
1250      void
1251      )
1252  {
1253      NV_REF           iter = NV_REF_INIT;
1254      NV_REF           currentAddr;
1255      UINT32           num = 0;
1256  //
1257      while((currentAddr = NvNextIndex(NULL, &iter)) != 0)
1258      {
1259          TPMA_NV             attributes = NvReadNvIndexAttributes(currentAddr);
1260          if(IsNvCounterIndex(attributes))
1261              num++;
1262      }
1263      return num;
1264  }
```

8.4.5.29 NvSetStartupAttributes()

Local function to set the attributes of an Index at TPM Reset and TPM Restart.

```
1265  static TPMA_NV
1266  NvSetStartupAttributes(
1267      TPMA_NV         attributes,         // IN: attributes to change
1268      STARTUP_TYPE     type               // IN: start up type
1269      )
1270  {
1271      // Clear read lock
```

```
1272        CLEAR_ATTRIBUTE(attributes, TPMA_NV, READLOCKED);
1273
1274        // Will change a non counter index to the unwritten state if:
1275        // a) TPMA_NV_CLEAR_STCLEAR is SET
1276        // b) orderly and TPM Reset
1277        if(!IsNvCounterIndex(attributes))
1278        {
1279            if(IS_ATTRIBUTE(attributes, TPMA_NV, CLEAR_STCLEAR)
1280               || (IS_ATTRIBUTE(attributes, TPMA_NV, ORDERLY)
1281                   && (type == SU_RESET)))
1282                CLEAR_ATTRIBUTE(attributes, TPMA_NV, WRITTEN);
1283        }
1284        // Unlock any index that is not written or that does not have
1285        // TPMA_NV_WRITEDEFINE SET.
1286        if(!IS_ATTRIBUTE(attributes, TPMA_NV, WRITTEN)
1287           || !IS_ATTRIBUTE(attributes, TPMA_NV, WRITEDEFINE))
1288            CLEAR_ATTRIBUTE(attributes, TPMA_NV, WRITELOCKED);
1289        return attributes;
1290    }
```

8.4.5.30 NvEntityStartup()

This function is called at TPM_Startup(). If the startup completes a TPM Resume cycle, no action is taken. If the startup is a TPM Reset or a TPM Restart, then this function will:

a) clear read/write lock;

b) reset NV Index data that has TPMA_NV_CLEAR_STCLEAR SET; and

c) set the lower bits in orderly counters to 1 for a non-orderly startup

It is a prerequisite that NV be available for writing before this function is called.

```
1291    BOOL
1292    NvEntityStartup(
1293        STARTUP_TYPE     type           // IN: start up type
1294        )
1295    {
1296        NV_REF                iter = NV_REF_INIT;
1297        NV_RAM_REF            ramIter = NV_RAM_REF_INIT;
1298        NV_REF                currentAddr;        // offset points to the current entity
1299        NV_RAM_REF            currentRamAddr;
1300        TPM_HANDLE            nvHandle;
1301        TPMA_NV               attributes;
1302    //
1303        // Restore RAM index data
1304        NvRead(s_indexOrderlyRam, NV_INDEX_RAM_DATA, sizeof(s_indexOrderlyRam));
1305
1306        // Initialize the max NV counter value
1307        NvSetMaxCount(NvGetMaxCount());
1308
1309        // If recovering from state save, do nothing else
1310        if(type == SU_RESUME)
1311            return TRUE;
1312        // Iterate all the NV Index to clear the locks
1313        while((currentAddr = NvNextIndex(&nvHandle, &iter)) != 0)
1314        {
1315            attributes = NvReadNvIndexAttributes(currentAddr);
1316
1317            // If this is an orderly index, defer processing until loop below
1318            if(IS_ATTRIBUTE(attributes, TPMA_NV, ORDERLY))
1319                continue;
1320            // Set the attributes appropriate for this startup type
1321            attributes = NvSetStartupAttributes(attributes, type);
1322            NvWriteNvIndexAttributes(currentAddr, attributes);
```

```
1323        }
1324        // Iterate all the orderly indexes to clear the locks and initialize counters
1325        while((currentRamAddr = NvRamNext(&ramIter, NULL)) != 0)
1326        {
1327            attributes = NvReadRamIndexAttributes(currentRamAddr);
1328
1329            attributes = NvSetStartupAttributes(attributes, type);
1330
1331            // update attributes in RAM
1332            NvWriteRamIndexAttributes(currentRamAddr, attributes);
1333
1334            // Set the lower bits in an orderly counter to 1 for a non-orderly startup
1335            if(IsNvCounterIndex(attributes)
1336               && (g_prevOrderlyState == SU_NONE_VALUE))
1337            {
1338                UINT64      counter;
1339    //
1340                // Read the counter value last saved to NV.
1341                counter = BYTE_ARRAY_TO_UINT64(currentRamAddr + sizeof(NV_RAM_HEADER));
1342
1343                // Set the lower bits of counter to 1's
1344                counter |= MAX_ORDERLY_COUNT;
1345
1346                // Write back to RAM
1347                // NOTE: Do not want to force a write to NV here. The counter value will
1348                // stay in RAM until the next shutdown or rollover.
1349                UINT64_TO_BYTE_ARRAY(counter, currentRamAddr + sizeof(NV_RAM_HEADER));
1350            }
1351        }
1352        return TRUE;
1353    }
```

8.4.5.31 NvCapGetCounterAvail()

This function returns an estimate of the number of additional counter type NV indexes that can be defined.

```
1354    UINT32
1355    NvCapGetCounterAvail(
1356        void
1357        )
1358    {
1359        UINT32          availNVSpace;
1360        UINT32          availRAMSpace;
1361        UINT32          persistentNum = NvCapGetPersistentNumber();
1362        UINT32          reserved = sizeof(NV_LIST_TERMINATOR);
1363    //
1364        // Get the available space in NV storage
1365        availNVSpace = NvGetFreeBytes();
1366
1367        if(persistentNum < MIN_EVICT_OBJECTS)
1368        {
1369            // Some space has to be reserved for evict object. Adjust availNVSpace.
1370            reserved += (MIN_EVICT_OBJECTS - persistentNum) * NV_EVICT_OBJECT_SIZE;
1371            if(reserved > availNVSpace)
1372                availNVSpace = 0;
1373            else
1374                availNVSpace -= reserved;
1375        }
1376        // Compute the available space in RAM
1377        availRAMSpace = (int)(RAM_ORDERLY_END - NvRamGetEnd());
1378
1379        // Return the min of counter number in NV and in RAM
1380        if(availNVSpace / NV_INDEX_COUNTER_SIZE
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
1381            > availRAMSpace / NV_RAM_INDEX_COUNTER_SIZE)
1382            return availRAMSpace / NV_RAM_INDEX_COUNTER_SIZE;
1383        else
1384            return availNVSpace / NV_INDEX_COUNTER_SIZE;
1385    }
```

8.4.5.32 NvFindHandle()

this function returns the offset in NV memory of the entity associated with the input handle. A value of zero indicates that handle does not exist reference an existing persistent object or defined NV Index.

```
1386    NV_REF
1387    NvFindHandle(
1388        TPM_HANDLE       handle
1389        )
1390    {
1391        NV_REF           addr;
1392        NV_REF           iter = NV_REF_INIT;
1393        TPM_HANDLE       nextHandle;
1394    //
1395        while((addr = NvNext(&iter, &nextHandle)) != 0)
1396        {
1397            if(nextHandle == handle)
1398                break;
1399        }
1400        return addr;
1401    }
```

8.4.6 NV Max Counter

8.4.6.1 Introduction

The TPM keeps track of the highest value of a deleted counter index. When an index is deleted, this value is updated if the deleted counter index is greater than the previous value. When a new index is created and first incremented, it will get a value that is at least one greater than any other index than any previously deleted index. This insures that it is not possible to roll back an index.

The highest counter value is keep in NV in a special end-of-list marker. This marker is only updated when an index is deleted. Otherwise it just moves.

When the TPM starts up, it searches NV for the end of list marker and initializes an in memory value (*s_maxCounter*).

8.4.6.2 NvReadMaxCount()

This function returns the max NV counter value.

```
1402    UINT64
1403    NvReadMaxCount(
1404        void
1405        )
1406    {
1407        return s_maxCounter;
1408    }
```

8.4.6.3 NvUpdateMaxCount()

This function updates the max counter value to NV memory. This is just staging for the actual write that will occur when the NV index memory is modified.

 Copyright © TCG 2006-2020

```
1409 void
1410 NvUpdateMaxCount(
1411     UINT64          count
1412     )
1413 {
1414     if(count > s_maxCounter)
1415         s_maxCounter = count;
1416 }
```

8.4.6.4 NvSetMaxCount()

This function is used at NV initialization time to set the initial value of the maximum counter.

```
1417 void
1418 NvSetMaxCount(
1419     UINT64          value
1420     )
1421 {
1422     s_maxCounter = value;
1423 }
```

8.4.6.5 NvGetMaxCount()

Function to get the NV max counter value from the end-of-list marker

```
1424 UINT64
1425 NvGetMaxCount(
1426     void
1427     )
1428 {
1429     NV_REF                 iter = NV_REF_INIT;
1430     NV_REF                 currentAddr;
1431     UINT64                 maxCount;
1432 //
1433     // Find the end of list marker and initialize the NV Max Counter value.
1434     while((currentAddr = NvNext(&iter, NULL )) != 0);
1435     // 'iter' should be pointing at the end of list marker so read in the current
1436     // value of the s_maxCounter.
1437     NvRead(&maxCount, iter + sizeof(UINT32), sizeof(maxCount));
1438
1439     return maxCount;
1440 }
```

8.5 NvReserved.c

8.5.1 Introduction

The NV memory is divided into two areas: dynamic space for user defined NV Indices and evict objects, and reserved space for TPM persistent and state save data.

The entries in dynamic space are a linked list of entries. Each entry has, as its first field, a size. If the size field is zero, it marks the end of the list.

An allocation of an Index or evict object may use almost all of the remaining NV space such that the size field will not fit. The functions that search the list are aware of this and will terminate the search if they either find a zero size or recognize that there is insufficient space for the size field.

An Index allocation will contain an NV_INDEX structure. If the Index does not have the orderly attribute, the NV_INDEX is followed immediately by the NV data.

An evict object entry contains a handle followed by an OBJECT structure. This results in both the Index and Evict Object having an identifying handle as the first field following the size field.

When an Index has the orderly attribute, the data is kept in RAM. This RAM is saved to backing store in NV memory on any orderly shutdown. The entries in orderly memory are also a linked list using a size field as the first entry. As with the NV memory, the list is terminated by a zero size field or when the last entry leaves insufficient space for the terminating size field.

The attributes of an orderly index are maintained in RAM memory in order to reduce the number of NV writes needed for orderly data. When an orderly index is created, an entry is made in the dynamic NV memory space that holds the Index authorizations (*authPolicy* and *authValue*) and the size of the data. This entry is only modified if the *authValue* of the index is changed. The more volatile data of the index is kept in RAM. When an orderly Index is created or deleted, the RAM data is copied to NV backing store so that the image in the backing store matches the layout of RAM. In normal operation. The RAM data is also copied on any orderly shutdown. In normal operation, the only other reason for writing to the backing store for RAM is when a counter is first written (TPMA_NV_WRITTEN changes from CLEAR to SET) or when a counter "rolls over."

Static space contains items that are individually modifiable. The values are in the *gp* PERSISTEND_DATA structure in RAM and mapped to locations in NV.

8.5.2 Includes, Defines

```
1    #define NV_C
2    #include    "Tpm.h"
```

8.5.3 Functions

8.5.3.1 NvInitStatic()

This function initializes the static variables used in the NV subsystem.

```
3    static void
4    NvInitStatic(
5        void
6        )
7    {
8        // In some implementations, the end of NV is variable and is set at boot time.
9        // This value will be the same for each boot, but is not necessarily known
10       // at compile time.
11       s_evictNvEnd = (NV_REF)NV_MEMORY_SIZE;
12       return;
```

```
13 }
```

8.5.3.2 NvCheckState()

Function to check the NV state by accessing the platform-specific function to get the NV state. The result state is registered in *s_NvIsAvailable* that will be reported by NvIsAvailable().

This function is called at the beginning of ExecuteCommand() before any potential check of *g_NvStatus*.

```
14 void
15 NvCheckState(
16     void
17     )
18 {
19     int      func_return;
20 //
21     func_return = _plat__IsNvAvailable();
22     if(func_return == 0)
23         g_NvStatus = TPM_RC_SUCCESS;
24     else if(func_return == 1)
25         g_NvStatus = TPM_RC_NV_UNAVAILABLE;
26     else
27         g_NvStatus = TPM_RC_NV_RATE;
28     return;
29 }
```

8.5.3.3 NvCommit

This is a wrapper for the platform function to commit pending NV writes.

```
30 BOOL
31 NvCommit(
32     void
33     )
34 {
35     return (_plat__NvCommit() == 0);
36 }
```

8.5.3.4 NvPowerOn()

This function is called at _TPM_Init() to initialize the NV environment.

Return Value	Meaning
TRUE(1)	all NV was initialized
FALSE(0)	the NV containing saved state had an error and TPM2_Startup(CLEAR) is required

```
37 BOOL
38 NvPowerOn(
39     void
40     )
41 {
42     int          nvError = 0;
43     // If power was lost, need to re-establish the RAM data that is loaded from
44     // NV and initialize the static variables
45     if(g_powerWasLost)
46     {
47         if((nvError = _plat__NVEnable(0)) < 0)
48             FAIL(FATAL_ERROR_NV_UNRECOVERABLE);
```

 Copyright © TCG 2006-2020

```
49          NvInitStatic();
50      }
51      return nvError == 0;
52  }
```

8.5.3.5 NvManufacture()

This function initializes the NV system at pre-install time.

This function should only be called in a manufacturing environment or in a simulation.

The layout of NV memory space is an implementation choice.

```
53  void
54  NvManufacture(
55      void
56      )
57  {
58  #if SIMULATION
59      // Simulate the NV memory being in the erased state.
60      _plat__NvMemoryClear(0, NV_MEMORY_SIZE);
61  #endif
62      // Initialize static variables
63      NvInitStatic();
64      // Clear the RAM used for Orderly Index data
65      MemorySet(s_indexOrderlyRam, 0, RAM_INDEX_SPACE);
66      // Write that Orderly Index data to NV
67      NvUpdateIndexOrderlyData();
68      // Initialize the next offset of the first entry in evict/index list to 0 (the
69      // end of list marker) and the initial s_maxCounterValue;
70      NvSetMaxCount(0);
71      // Put the end of list marker at the end of memory. This contains the MaxCount
72      // value as well as the end marker.
73      NvWriteNvListEnd(NV_USER_DYNAMIC);
74      return;
75  }
```

8.5.3.6 NvRead()

This function is used to move reserved data from NV memory to RAM.

```
76  void
77  NvRead(
78      void            *outBuffer,     // OUT: buffer to receive data
79      UINT32           nvOffset,      // IN: offset in NV of value
80      UINT32           size           // IN: size of the value to read
81      )
82  {
83      // Input type should be valid
84      pAssert(nvOffset + size < NV_MEMORY_SIZE);
85      _plat__NvMemoryRead(nvOffset, size, outBuffer);
86      return;
87  }
```

8.5.3.7 NvWrite()

This function is used to post reserved data for writing to NV memory. Before the TPM completes the operation, the value will be written.

```
88  BOOL
89  NvWrite(
90      UINT32           nvOffset,      // IN: location in NV to receive data
```

```
 91         UINT32            size,          // IN: size of the data to move
 92         void             *inBuffer       // IN: location containing data to write
 93         )
 94     {
 95         // Input type should be valid
 96         if(nvOffset + size <= NV_MEMORY_SIZE)
 97         {
 98             // Set the flag that a NV write happened
 99             SET_NV_UPDATE(UT_NV);
100             return _plat__NvMemoryWrite(nvOffset, size, inBuffer);
101         }
102         return FALSE;
103     }
```

8.5.3.8 NvUpdatePersistent()

This function is used to update a value in the PERSISTENT_DATA structure and commits the value to NV.

```
104     void
105     NvUpdatePersistent(
106         UINT32            offset,        // IN: location in PERMANENT_DATA to be updated
107         UINT32            size,          // IN: size of the value
108         void             *buffer         // IN: the new data
109         )
110     {
111         pAssert(offset + size <= sizeof(gp));
112         MemoryCopy(&gp + offset, buffer, size);
113         NvWrite(offset, size, buffer);
114     }
```

8.5.3.9 NvClearPersistent()

This function is used to clear a persistent data entry and commit it to NV

```
115     void
116     NvClearPersistent(
117         UINT32            offset,        // IN: the offset in the PERMANENT_DATA
118                                          //     structure to be cleared (zeroed)
119         UINT32            size           // IN: number of bytes to clear
120         )
121     {
122         pAssert(offset + size <= sizeof(gp));
123         MemorySet((&gp) + offset, 0, size);
124         NvWrite(offset, size, (&gp) + offset);
125     }
```

8.5.3.10 NvReadPersistent()

This function reads persistent data to the RAM copy of the *gp* structure.

```
126     void
127     NvReadPersistent(
128         void
129         )
130     {
131         NvRead(&gp, NV_PERSISTENT_DATA, sizeof(gp));
132         return;
133     }
```

8.6 Object.c

8.6.1 Introduction

This file contains the functions that manage the object store of the TPM.

8.6.2 Includes and Data Definitions

```
1    #define OBJECT_C
2    #include "Tpm.h"
```

8.6.3 Functions

8.6.3.1 ObjectFlush()

This function marks an object slot as available. Since there is no checking of the input parameters, it should be used judiciously.

NOTE: This could be converted to a macro.

```
3    void
4    ObjectFlush(
5        OBJECT          *object
6        )
7    {
8        object->attributes.occupied = CLEAR;
9    }
```

8.6.3.2 ObjectSetInUse()

This access function sets the occupied attribute of an object slot.

```
10   void
11   ObjectSetInUse(
12       OBJECT          *object
13       )
14   {
15       object->attributes.occupied = SET;
16   }
```

8.6.3.3 ObjectStartup()

This function is called at TPM2_Startup() to initialize the object subsystem.

```
17   BOOL
18   ObjectStartup(
19       void
20       )
21   {
22       UINT32      i;
23   //
24       // object slots initialization
25       for(i = 0; i < MAX_LOADED_OBJECTS; i++)
26       {
27           //Set the slot to not occupied
28           ObjectFlush(&s_objects[i]);
29       }
```

```
30      return TRUE;
31  }
```

8.6.3.4 ObjectCleanupEvict()

In this implementation, a persistent object is moved from NV into an object slot for processing. It is flushed after command execution. This function is called from ExecuteCommand().

```
32  void
33  ObjectCleanupEvict(
34      void
35      )
36  {
37      UINT32      i;
38  //
39      // This has to be iterated because a command may have two handles
40      // and they may both be persistent.
41      // This could be made to be more efficient so that a search is not needed.
42      for(i = 0; i < MAX_LOADED_OBJECTS; i++)
43      {
44          // If an object is a temporary evict object, flush it from slot
45          OBJECT      *object = &s_objects[i];
46          if(object->attributes.evict == SET)
47              ObjectFlush(object);
48      }
49      return;
50  }
```

8.6.3.5 IsObjectPresent()

This function checks to see if a transient handle references a loaded object. This routine should not be called if the handle is not a transient handle. The function validates that the handle is in the implementation-dependent allowed in range for loaded transient objects.

Return Value	Meaning
TRUE(1)	handle references a loaded object
FALSE(0)	handle is not an object handle, or it does not reference to a loaded object

```
51  BOOL
52  IsObjectPresent(
53      TPMI_DH_OBJECT   handle         // IN: handle to be checked
54      )
55  {
56      UINT32          slotIndex = handle - TRANSIENT_FIRST;
57      // Since the handle is just an index into the array that is zero based, any
58      // handle value outsize of the range of:
59      //    TRANSIENT_FIRST -- (TRANSIENT_FIRST + MAX_LOADED_OBJECT - 1)
60      // will now be greater than or equal to MAX_LOADED_OBJECTS
61      if(slotIndex >= MAX_LOADED_OBJECTS)
62          return FALSE;
63      // Indicate if the slot is occupied
64      return (s_objects[slotIndex].attributes.occupied == TRUE);
65  }
```

8.6.3.6 ObjectIsSequence()

This function is used to check if the object is a sequence object. This function should not be called if the handle does not reference a loaded object.

Return Value	Meaning
TRUE(1)	object is an HMAC, hash, or event sequence object
FALSE(0)	object is not an HMAC, hash, or event sequence object

```
66  BOOL
67  ObjectIsSequence(
68      OBJECT          *object         // IN: handle to be checked
69      )
70  {
71      pAssert(object != NULL);
72      return (object->attributes.hmacSeq == SET
73              || object->attributes.hashSeq == SET
74              || object->attributes.eventSeq == SET);
75  }
```

8.6.3.7 HandleToObject()

This function is used to find the object structure associated with a handle.

This function requires that *handle* references a loaded object or a permanent handle.

```
76  OBJECT*
77  HandleToObject(
78      TPMI_DH_OBJECT   handle         // IN: handle of the object
79      )
80  {
81      UINT32              index;
82  //
83      // Return NULL if the handle references a permanent handle because there is no
84      // associated OBJECT.
85      if(HandleGetType(handle) == TPM_HT_PERMANENT)
86          return NULL;
87      // In this implementation, the handle is determined by the slot occupied by the
88      // object.
89      index = handle - TRANSIENT_FIRST;
90      pAssert(index < MAX_LOADED_OBJECTS);
91      pAssert(s_objects[index].attributes.occupied);
92      return &s_objects[index];
93  }
```

8.6.3.8 GetQualifiedName()

This function returns the Qualified Name of the object. In this implementation, the Qualified Name is computed when the object is loaded and is saved in the internal representation of the object. The alternative would be to retain the Name of the parent and compute the QN when needed. This would take the same amount of space so it is not recommended that the alternate be used.

This function requires that *handle* references a loaded object.

```
94  void
95  GetQualifiedName(
96      TPMI_DH_OBJECT   handle,        // IN: handle of the object
97      TPM2B_NAME      *qualifiedName  // OUT: qualified name of the object
98      )
99  {
100     OBJECT      *object;
101 //
102     switch(HandleGetType(handle))
103     {
104         case TPM_HT_PERMANENT:
```

```
105                 qualifiedName->t.size = sizeof(TPM_HANDLE);
106                 UINT32_TO_BYTE_ARRAY(handle, qualifiedName->t.name);
107                 break;
108             case TPM_HT_TRANSIENT:
109                 object = HandleToObject(handle);
110                 if(object == NULL || object->publicArea.nameAlg == TPM_ALG_NULL)
111                     qualifiedName->t.size = 0;
112                 else
113                     // Copy the name
114                     *qualifiedName = object->qualifiedName;
115                 break;
116             default:
117                 FAIL(FATAL_ERROR_INTERNAL);
118         }
119         return;
120     }
```

8.6.3.9 ObjectGetHierarchy()

This function returns the handle for the hierarchy of an object.

```
121     TPMI_RH_HIERARCHY
122     ObjectGetHierarchy(
123         OBJECT          *object         // IN :object
124         )
125     {
126         if(object->attributes.spsHierarchy)
127         {
128             return TPM_RH_OWNER;
129         }
130         else if(object->attributes.epsHierarchy)
131         {
132             return TPM_RH_ENDORSEMENT;
133         }
134         else if(object->attributes.ppsHierarchy)
135         {
136             return TPM_RH_PLATFORM;
137         }
138         else
139         {
140             return TPM_RH_NULL;
141         }
142     }
```

8.6.3.10 GetHeriarchy()

This function returns the handle of the hierarchy to which a handle belongs. This function is similar to ObjectGetHierarchy() but this routine takes a handle while ObjectGetHierarchy() takes an pointer to an object.

This function requires that *handle* references a loaded object.

```
143     TPMI_RH_HIERARCHY
144     GetHeriarchy(
145         TPMI_DH_OBJECT   handle         // IN :object handle
146         )
147     {
148         OBJECT          *object = HandleToObject(handle);
149     //
150         return ObjectGetHierarchy(object);
151     }
```

 Copyright © TCG 2006-2020

8.6.3.11 FindEmptyObjectSlot()

This function finds an open object slot, if any. It will clear the attributes but will not set the occupied attribute. This is so that a slot may be used and discarded if everything does not go as planned.

Return Value	Meaning
NULL	no open slot found
NULL	pointer to available slot

```
152 OBJECT *
153 FindEmptyObjectSlot(
154     TPMI_DH_OBJECT   *handle          // OUT: (optional)
155     )
156 {
157     UINT32               i;
158     OBJECT              *object;
159 //
160     for(i = 0; i < MAX_LOADED_OBJECTS; i++)
161     {
162         object = &s_objects[i];
163         if(object->attributes.occupied == CLEAR)
164         {
165             if(handle)
166                 *handle = i + TRANSIENT_FIRST;
167             // Initialize the object attributes
168             MemorySet(&object->attributes, 0, sizeof(OBJECT_ATTRIBUTES));
169             return object;
170         }
171     }
172     return NULL;
173 }
```

8.6.3.12 ObjectAllocateSlot()

This function is used to allocate a slot in internal object array.

```
174 OBJECT *
175 ObjectAllocateSlot(
176     TPMI_DH_OBJECT   *handle         // OUT: handle of allocated object
177     )
178 {
179     OBJECT           *object = FindEmptyObjectSlot(handle);
180 //
181     if(object != NULL)
182     {
183         // if found, mark as occupied
184         ObjectSetInUse(object);
185     }
186     return object;
187 }
```

8.6.3.13 ObjectSetLoadedAttributes()

This function sets the internal attributes for a loaded object. It is called to finalize the OBJECT attributes (not the TPMA_OBJECT attributes) for a loaded object.

```
188 void
189 ObjectSetLoadedAttributes(
190     OBJECT           *object,         // IN: object attributes to finalize
191     TPM_HANDLE        parentHandle    // IN: the parent handle
```

 Copyright © TCG 2006-2020

```
192         )
193     {
194         OBJECT                *parent = HandleToObject(parentHandle);
195         TPMA_OBJECT            objectAttributes = object->publicArea.objectAttributes;
196     //
197         // Copy the stClear attribute from the public area. This could be overwritten
198         // if the parent has stClear SET
199         object->attributes.stClear =
200             IS_ATTRIBUTE(objectAttributes, TPMA_OBJECT, stClear);
201         // If parent handle is a permanent handle, it is a primary (unless it is NULL
202         if(parent == NULL)
203         {
204             object->attributes.primary = SET;
205             switch(parentHandle)
206             {
207                 case TPM_RH_ENDORSEMENT:
208                     object->attributes.epsHierarchy = SET;
209                     break;
210                 case TPM_RH_OWNER:
211                     object->attributes.spsHierarchy = SET;
212                     break;
213                 case TPM_RH_PLATFORM:
214                     object->attributes.ppsHierarchy = SET;
215                     break;
216                 default:
217                     // Treat the temporary attribute as a hierarchy
218                     object->attributes.temporary = SET;
219                     object->attributes.primary = CLEAR;
220                     break;
221             }
222         }
223         else
224         {
225             // is this a stClear object
226             object->attributes.stClear =
227                 (IS_ATTRIBUTE(objectAttributes, TPMA_OBJECT, stClear)
228                  || (parent->attributes.stClear == SET));
229             object->attributes.epsHierarchy = parent->attributes.epsHierarchy;
230             object->attributes.spsHierarchy = parent->attributes.spsHierarchy;
231             object->attributes.ppsHierarchy = parent->attributes.ppsHierarchy;
232             // An object is temporary if its parent is temporary or if the object
233             // is external
234             object->attributes.temporary = parent->attributes.temporary
235                 || object->attributes.external;
236         }
237         // If this is an external object, set the QN == name but don't SET other
238         // key properties ('parent' or 'derived')
239         if(object->attributes.external)
240             object->qualifiedName = object->name;
241         else
242         {
243             // check attributes for different types of parents
244             if(IS_ATTRIBUTE(objectAttributes, TPMA_OBJECT, restricted)
245                && !object->attributes.publicOnly
246                && IS_ATTRIBUTE(objectAttributes, TPMA_OBJECT, decrypt)
247                && object->publicArea.nameAlg != TPM_ALG_NULL)
248             {
249                 // This is a parent. If it is not a KEYEDHASH, it is an ordinary parent.
250                 // Otherwise, it is a derivation parent.
251                 if(object->publicArea.type == TPM_ALG_KEYEDHASH)
252                     object->attributes.derivation = SET;
253                 else
254                     object->attributes.isParent = SET;
255             }
256             ComputeQualifiedName(parentHandle, object->publicArea.nameAlg,
257                                  &object->name, &object->qualifiedName);
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
258         }
259         // Set slot occupied
260         ObjectSetInUse(object);
261         return;
262     }
```

8.6.3.14 ObjectLoad()

Common function to load an object. A loaded object has its public area validated (unless its *nameAlg* is TPM_ALG_NULL). If a sensitive part is loaded, it is verified to be correct and if both public and sensitive parts are loaded, then the cryptographic binding between the objects is validated. This function does not cause the allocated slot to be marked as in use.

```
263     TPM_RC
264     ObjectLoad(
265         OBJECT           *object,         // IN: pointer to object slot
266                                           //     object
267         OBJECT           *parent,         // IN: (optional) the parent object
268         TPMT_PUBLIC      *publicArea,     // IN: public area to be installed in the object
269         TPMT_SENSITIVE   *sensitive,      // IN: (optional) sensitive area to be
270                                           //      installed in the object
271         TPM_RC            blamePublic,    // IN: parameter number to associate with the
272                                           //     publicArea errors
273         TPM_RC            blameSensitive,// IN: parameter number to associate with the
274                                           //     sensitive area errors
275         TPM2B_NAME       *name            // IN: (optional)
276     )
277     {

429      if(hashObject == NULL)
430          return TPM_RC_OBJECT_MEMORY;
431      // Set hash sequence bit
432      hashObject->attributes.hashSeq = SET;
433
434      // Start hash for hash sequence
435      CryptHashStart(&hashObject->state.hashState[0], hashAlg);
436
437      return TPM_RC_SUCCESS;
438  }
```

8.6.3.18 ObjectCreateEventSequence()

This function creates an event sequence object.

Error Returns	Meaning
TPM_RC_OBJECT_MEMORY	if there is no free slot for an object

```
439  TPM_RC
440  ObjectCreateEventSequence(
441      TPM2B_AUTH      *auth,             // IN: authValue
442      TPMI_DH_OBJECT  *newHandle         // OUT: sequence object handle
443      )
444  {
445      HASH_OBJECT          *hashObject = AllocateSequenceSlot(newHandle, auth);
446      UINT32                count;
447      TPM_ALG_ID            hash;
448  //
449      // See if slot allocated
450      if(hashObject == NULL)
451          return TPM_RC_OBJECT_MEMORY;
452      // Set the event sequence attribute
453      hashObject->attributes.eventSeq = SET;
454
455      // Initialize hash states for each implemented PCR algorithms
456      for(count = 0; (hash = CryptHashGetAlgByIndex(count)) != TPM_ALG_NULL; count++)
457          CryptHashStart(&hashObject->state.hashState[count], hash);
458      return TPM_RC_SUCCESS;
459  }
```

8.6.3.19 ObjectTerminateEvent()

This function is called to close out the event sequence and clean up the hash context states.

```
460  void
461  ObjectTerminateEvent(
462      void
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
463         )
464     {
465         HASH_OBJECT          *hashObject;
466         int                   count;
467         BYTE                  buffer[MAX_DIGEST_SIZE];
468     //
469         hashObject = (HASH_OBJECT *)HandleToObject(g_DRTMHandle);
470
471         // Don't assume that this is a proper sequence object
472         if(hashObject->attributes.eventSeq)
473         {
474             // If it is, close any open hash contexts. This is done in case
475             // the cryptographic implementation has some context values that need to be
476             // cleaned up (hygiene).
477             //
478             for(count = 0; CryptHashGetAlgByIndex(count) != TPM_ALG_NULL; count++)
479             {
480                 CryptHashEnd(&hashObject->state.hashState[count], 0, buffer);
481             }
482             // Flush sequence object
483             FlushObject(g_DRTMHandle);
484         }
485         g_DRTMHandle = TPM_RH_UNASSIGNED;
486     }
```

8.6.3.20 ObjectContextLoad()

This function loads an object from a saved object context.

Return Value	Meaning
NULL	if there is no free slot for an object
NULL	points to the loaded object

```
487     OBJECT *
488     ObjectContextLoad(
489         ANY_OBJECT_BUFFER   *object,         // IN: pointer to object structure in saved
490                                              //     context
491         TPMI_DH_OBJECT      *handle          // OUT: object handle
492         )
493     {
494         OBJECT      *newObject = ObjectAllocateSlot(handle);
495     //
496         // Try to allocate a slot for new object
497         if(newObject != NULL)
498         {
499             // Copy the first part of the object
500             MemoryCopy(newObject, object, offsetof(HASH_OBJECT, state));
501             // See if this is a sequence object
502             if(ObjectIsSequence(newObject))
503             {
504                 // If this is a sequence object, import the data
505                 SequenceDataImport((HASH_OBJECT *)newObject,
506                                    (HASH_OBJECT_BUFFER *)object);
507             }
508             else
509             {
510                 // Copy input object data to internal structure
511                 MemoryCopy(newObject, object, sizeof(OBJECT));
512             }
513         }
514         return newObject;
515     }
```

 Copyright © TCG 2006-2020

8.6.3.21 FlushObject()

This function frees an object slot.

This function requires that the object is loaded.

```
516 void
517 FlushObject(
518     TPMI_DH_OBJECT    handle          // IN: handle to be freed
519     )
520 {
521     UINT32       index = handle - TRANSIENT_FIRST;
522 //
523     pAssert(index < MAX_LOADED_OBJECTS);
524     // Clear all the object attributes
525     MemorySet((BYTE*)&(s_objects[index].attributes),
526               0, sizeof(OBJECT_ATTRIBUTES));
527     return;
528 }
```

8.6.3.22 ObjectFlushHierarchy()

This function is called to flush all the loaded transient objects associated with a hierarchy when the hierarchy is disabled.

```
529 void
530 ObjectFlushHierarchy(
531     TPMI_RH_HIERARCHY     hierarchy      // IN: hierarchy to be flush
532     )
533 {
534     UINT16          i;
535 //
536     // iterate object slots
537     for(i = 0; i < MAX_LOADED_OBJECTS; i++)
538     {
539         if(s_objects[i].attributes.occupied)          // If found an occupied slot
540         {
541             switch(hierarchy)
542             {
543                 case TPM_RH_PLATFORM:
544                     if(s_objects[i].attributes.ppsHierarchy == SET)
545                         s_objects[i].attributes.occupied = FALSE;
546                     break;
547                 case TPM_RH_OWNER:
548                     if(s_objects[i].attributes.spsHierarchy == SET)

550                     break;
551                 case TPM_RH_ENDORSEMENT:
552                     if(s_objects[i].attributes.epsHierarchy == SET)
553                         s_objects[i].attributes.occupied = FALSE;
554                     break;
555                 default:
556                     FAIL(FATAL_ERROR_INTERNAL);
557                     break;
558             }
559         }
560     }
561
562     return;
563 }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

8.6.3.23 ObjectLoadEvict()

This function loads a persistent object into a transient object slot.

This function requires that *handle* is associated with a persistent object.

Error Returns	Meaning
TPM_RC_HANDLE	the persistent object does not exist or the associated hierarchy is disabled.
TPM_RC_OBJECT_MEMORY	no object slot

```
564 TPM_RC
565 ObjectLoadEvict(
566     TPM_HANDLE      *handle,        // IN:OUT: evict object handle.  If success, it
567                                     // will be replace by the loaded object handle
568     COMMAND_INDEX    commandIndex   // IN: the command being processed
569     )
570 {
571     TPM_RC          result;
572     TPM_HANDLE      evictHandle = *handle;   // Save the evict handle
573     OBJECT          *object;
574 //
575     // If this is an index that references a persistent object created by
576     // the platform, then return TPM_RH_HANDLE if the phEnable is FALSE
577     if(*handle >= PLATFORM_PERSISTENT)
578     {
579         // belongs to platform
580         if(g_phEnable == CLEAR)
581             return TPM_RC_HANDLE;
582     }
583     // belongs to owner
584     else if(gc.shEnable == CLEAR)
585         return TPM_RC_HANDLE;
586     // Try to allocate a slot for an object
587     object = ObjectAllocateSlot(handle);
588     if(object == NULL)
589         return TPM_RC_OBJECT_MEMORY;
590     // Copy persistent object to transient object slot.  A TPM_RC_HANDLE
591     // may be returned at this point. This will mark the slot as containing
592     // a transient object so that it will be flushed at the end of the
593     // command
594     result = NvGetEvictObject(evictHandle, object);
595
596     // Bail out if this failed
597     if(result != TPM_RC_SUCCESS)
598         return result;
599     // check the object to see if it is in the endorsement hierarchy
600     // if it is and this is not a TPM2_EvictControl() command, indicate
601     // that the hierarchy is disabled.
602     // If the associated hierarchy is disabled, make it look like the
603     // handle is not defined
604     if(ObjectGetHierarchy(object) == TPM_RH_ENDORSEMENT
605        && gc.ehEnable == CLEAR
606        && GetCommandCode(commandIndex) != TPM_CC_EvictControl)
607         return TPM_RC_HANDLE;
608
609     return result;
610 }
```

8.6.3.24 ObjectComputeName()

This does the name computation from a public area (can be marshaled or not).

```
611 TPM2B_NAME *
612 ObjectComputeName(
613     UINT32           size,          // IN: the size of the area to digest
614     BYTE            *publicArea,    // IN: the public area to digest
615     TPM_ALG_ID       nameAlg,       // IN: the hash algorithm to use
616     TPM2B_NAME      *name           // OUT: Computed name
617     )
618 {
619     // Hash the publicArea into the name buffer leaving room for the nameAlg
620     name->t.size = CryptHashBlock(nameAlg, size, publicArea,
621                                   sizeof(name->t.name) - 2,
622                                   &name->t.name[2]);
623     // set the nameAlg
624     UINT16_TO_BYTE_ARRAY(nameAlg, name->t.name);
625     name->t.size += 2;
626     return name;
627 }
```

8.6.3.25 PublicMarshalAndComputeName()

This function computes the Name of an object from its public area.

```
628 TPM2B_NAME *
629 PublicMarshalAndComputeName(
630     TPMT_PUBLIC     *publicArea,    // IN: public area of an object
631     TPM2B_NAME      *name           // OUT: name of the object
632     )
633 {
634     // Will marshal a public area into a template. This is because the internal
635     // format for a TPM2B_PUBLIC is a structure and not a simple BYTE buffer.
636     TPM2B_TEMPLATE       marshaled;     // this is big enough to hold a
637                                         //  marshaled TPMT_PUBLIC
638     BYTE                *buffer = (BYTE *)&marshaled.t.buffer;
639 //
640     // if the nameAlg is NULL then there is no name.
641     if(publicArea->nameAlg == TPM_ALG_NULL)
642         name->t.size = 0;
643     else
644     {
645         // Marshal the public area into its canonical form
646         marshaled.t.size = TPMT_PUBLIC_Marshal(publicArea, &buffer, NULL);
647         // and compute the name
648         ObjectComputeName(marshaled.t.size, marshaled.t.buffer,
649                           publicArea->nameAlg, name);
650     }
651     return name;
652 }
```

8.6.3.26 ComputeQualifiedName()

This function computes the qualified name of an object.

```
653 void
654 ComputeQualifiedName(
655     TPM_HANDLE       parentHandle,  // IN: parent's handle
656     TPM_ALG_ID       nameAlg,       // IN: name hash
657     TPM2B_NAME      *name,          // IN: name of the object
658     TPM2B_NAME      *qualifiedName  // OUT: qualified name of the object
659     )
660 {
661     HASH_STATE      hashState;   // hash state
662     TPM2B_NAME      parentName;
663 //
```

 Copyright © TCG 2006-2020

```
664         if(parentHandle == TPM_RH_UNASSIGNED)
665         {
666             MemoryCopy2B(&qualifiedName->b, &name->b, sizeof(qualifiedName->t.name));
667             *qualifiedName = *name;
668         }
669         else
670         {
671             GetQualifiedName(parentHandle, &parentName);
672
673             //      QN_A = hash_A (QN of parent || NAME_A)
674
675             // Start hash
676             qualifiedName->t.size = CryptHashStart(&hashState, nameAlg);
677
678             // Add parent's qualified name
679             CryptDigestUpdate2B(&hashState, &parentName.b);
680
681             // Add self name
682             CryptDigestUpdate2B(&hashState, &name->b);
683
684             // Complete hash leaving room for the name algorithm
685             CryptHashEnd(&hashState, qualifiedName->t.size,
686                          &qualifiedName->t.name[2]);
687             UINT16_TO_BYTE_ARRAY(nameAlg, qualifiedName->t.name);
688             qualifiedName->t.size += 2;
689         }
690         return;
691     }
```

8.6.3.27 ObjectIsStorage()

This function determines if an object has the attributes associated with a parent. A parent is an asymmetric or symmetric block cipher key that has its *restricted* and *decrypt* attributes SET, and *sign* CLEAR.

Return Value	Meaning
TRUE(1)	object is a storage key
FALSE(0)	object is not a storage key

```
692     BOOL
693     ObjectIsStorage(
694         TPMI_DH_OBJECT    handle         // IN: object handle
695         )
696     {
697         OBJECT           *object = HandleToObject(handle);
698         TPMT_PUBLIC      *publicArea = ((object != NULL) ? &object->publicArea : NULL);
699     //
700         return (publicArea != NULL
701                 && IS_ATTRIBUTE(publicArea->objectAttributes, TPMA_OBJECT, restricted)
702                 && IS_ATTRIBUTE(publicArea->objectAttributes, TPMA_OBJECT, decrypt)
703                 && !IS_ATTRIBUTE(publicArea->objectAttributes, TPMA_OBJECT, sign)
704                 && (object->publicArea.type == ALG_RSA_VALUE
705                     || object->publicArea.type == ALG_ECC_VALUE));
706     }
```

8.6.3.28 ObjectCapGetLoaded()

This function returns a a list of handles of loaded object, starting from *handle*. *Handle* must be in the range of valid transient object handles, but does not have to be the handle of a loaded transient object.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
707  TPMI_YES_NO
708  ObjectCapGetLoaded(
709      TPMI_DH_OBJECT    handle,        // IN: start handle
710      UINT32            count,         // IN: count of returned handles
711      TPML_HANDLE      *handleList     // OUT: list of handle
712      )
713  {
714      TPMI_YES_NO          more = NO;
715      UINT32               i;
716  //
717      pAssert(HandleGetType(handle) == TPM_HT_TRANSIENT);
718
719      // Initialize output handle list
720      handleList->count = 0;
721
722      // The maximum count of handles we may return is MAX_CAP_HANDLES
723      if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
724
725      // Iterate object slots to get loaded object handles
726      for(i = handle - TRANSIENT_FIRST; i < MAX_LOADED_OBJECTS; i++)
727      {
728          if(s_objects[i].attributes.occupied == TRUE)
729          {
730              // A valid transient object can not be the copy of a persistent object
731              pAssert(s_objects[i].attributes.evict == CLEAR);
732
733              if(handleList->count < count)
734              {
735                  // If we have not filled up the return list, add this object
736                  // handle to it
737                  handleList->handle[handleList->count] = i + TRANSIENT_FIRST;
738                  handleList->count++;
739              }
740              else
741              {
742                  // If the return list is full but we still have loaded object
743                  // available, report this and stop iterating
744                  more = YES;
745                  break;
746              }
747          }
748      }
749
750      return more;
751  }
```

8.6.3.29 ObjectCapGetTransientAvail()

This function returns an estimate of the number of additional transient objects that could be loaded into the TPM.

```
752  UINT32
753  ObjectCapGetTransientAvail(
754      void
755      )
756  {
757      UINT32       i;
758      UINT32       num = 0;
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
759 //
760     // Iterate object slot to get the number of unoccupied slots
761     for(i = 0; i < MAX_LOADED_OBJECTS; i++)
762     {
763         if(s_objects[i].attributes.occupied == FALSE) num++;
764     }
765
766     return num;
767 }
```

8.6.3.30 ObjectGetPublicAttributes()

Returns the attributes associated with an object handles.

```
768 TPMA_OBJECT
769 ObjectGetPublicAttributes(
770     TPM_HANDLE       handle
771     )
772 {
773     return HandleToObject(handle)->publicArea.objectAttributes;
774 }
775 OBJECT_ATTRIBUTES
776 ObjectGetProperties(
777     TPM_HANDLE       handle
778     )
779 {
780     return HandleToObject(handle)->attributes;
781 }
```

8.7 PCR.c

8.7.1 Introduction

This function contains the functions needed for PCR access and manipulation.

This implementation uses a static allocation for the PCR. The amount of memory is allocated based on the number of PCR in the implementation and the number of implemented hash algorithms. This is not the expected implementation. PCR SPACE DEFINITIONS.

In the definitions below, the *g_hashPcrMap* is a bit array that indicates which of the PCR are implemented. The *g_hashPcr* array is an array of digests. In this implementation, the space is allocated whether the PCR is implemented or not.

8.7.2 Includes, Defines, and Data Definitions

```
1  #define PCR_C
2  #include "Tpm.h"
```

The initial value of PCR attributes. The value of these fields should be consistent with PC Client specification In this implementation, we assume the total number of implemented PCR is 24.

```
3  static const PCR_Attributes s_initAttributes[] =
4  {
5      // PCR 0 - 15, static RTM
6      {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F},
7      {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F},
8      {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F},
9      {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F}, {1, 0, 0x1F},
10
11     {0, 0x0F, 0x1F},        // PCR 16, Debug
12     {0, 0x10, 0x1C},        // PCR 17, Locality 4
13     {0, 0x10, 0x1C},        // PCR 18, Locality 3
14     {0, 0x10, 0x0C},        // PCR 19, Locality 2
15     {0, 0x14, 0x0E},        // PCR 20, Locality 1
16     {0, 0x14, 0x04},        // PCR 21, Dynamic OS
17     {0, 0x14, 0x04},        // PCR 22, Dynamic OS

19     {0, 0x0F, 0x1F}         // PCR 24, testing policy
20 };
21
22 //** Functions
23
24 //*** PCRBelongsAuthGroup()
25 // This function indicates if a PCR belongs to a group that requires an authValue
26 // in order to modify the PCR.  If it does, 'groupIndex' is set to value of
27 // the group index.  This feature of PCR is decided by the platform specification.
```

Return Value	Meaning
TRUE(1)	PCR belongs to an authorization group
FALSE(0)	PCR belongs to an authorization group

```
28 BOOL
29 PCRBelongsAuthGroup(
30     TPMI_DH_PCR      handle,         // IN: handle of PCR
31     UINT32          *groupIndex      // OUT: group index if PCR belongs a
32                                      //      group that allows authValue.  If PCR
33                                      //      does not belong to an authorization
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
34                                      //      group, the value in this parameter is
35                                      //      invalid
36      )
37  {
38  #if defined NUM_AUTHVALUE_PCR_GROUP && NUM_AUTHVALUE_PCR_GROUP > 0
39      // Platform specification determines to which authorization group a PCR belongs
40      // (if any). In this implementation, we assume there is only
41      // one authorization group which contains PCR[20-22].  If the platform
42      // specification requires differently, the implementation should be changed
43      // accordingly
44      if(handle >= 20 && handle <= 22)
45      {
46          *groupIndex = 0;
47          return TRUE;
48      }
49
50  #endif
51      return FALSE;
52  }
```

8.7.2.1 PCRBelongsPolicyGroup()

This function indicates if a PCR belongs to a group that requires a policy authorization in order to modify the PCR. If it does, *groupIndex* is set to value of the group index. This feature of PCR is decided by the platform specification.

Return Value	Meaning
TRUE(1)	PCR belongs to a policy group
FALSE(0)	PCR does not belong to a policy group

```
53  BOOL
54  PCRBelongsPolicyGroup(
55      TPMI_DH_PCR      handle,        // IN: handle of PCR
56      UINT32          *groupIndex     // OUT: group index if PCR belongs a group that
57                                      //     allows policy.  If PCR does not belong to
58                                      //     a policy group, the value in this
59                                      //     parameter is invalid
60      )
61  {
62  #if defined NUM_POLICY_PCR_GROUP && NUM_POLICY_PCR_GROUP > 0
63      // Platform specification decides if a PCR belongs to a policy group and
64      // belongs to which group.  In this implementation, we assume there is only
65      // one policy group which contains PCR20-22.  If the platform specification
66      // requires differently, the implementation should be changed accordingly
67      if(handle >= 20 && handle <= 22)
68      {
69          *groupIndex = 0;
70          return TRUE;
71      }
72  #endif
73      return FALSE;
74  }
```

8.7.2.2 PCRBelongsTCBGroup()

This function indicates if a PCR belongs to the TCB group.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

Return Value	Meaning
TRUE(1)	PCR belongs to a TCB group
FALSE(0)	PCR does not belong to a TCB group

```
75   static BOOL
76   PCRBelongsTCBGroup(
77       TPMI_DH_PCR      handle          // IN: handle of PCR
78       )
79   {
80   #if ENABLE_PCR_NO_INCREMENT == YES
81       // Platform specification decides if a PCR belongs to a TCB group.  In this
82       // implementation, we assume PCR[20-22] belong to TCB group.  If the platform
83       // specification requires differently, the implementation should be
84       // changed accordingly
85       if(handle >= 20 && handle <= 22)
86           return TRUE;
87
88   #endif
89       return FALSE;
90   }
```

8.7.2.3 PCRPolicyIsAvailable()

This function indicates if a policy is available for a PCR.

Return Value	Meaning
TRUE(1)	the PCR may be authorized by policy
FALSE(0)	the PCR does not allow policy

```
91   BOOL
92   PCRPolicyIsAvailable(
93       TPMI_DH_PCR      handle          // IN: PCR handle
94       )
95   {
96       UINT32          groupIndex;
97
98       return PCRBelongsPolicyGroup(handle, &groupIndex);
99   }
```

8.7.2.4 PCRGetAuthValue()

This function is used to access the *authValue* of a PCR. If PCR does not belong to an *authValue* group, an EmptyAuth() will be returned.

```
100  TPM2B_AUTH *
101  PCRGetAuthValue(
102      TPMI_DH_PCR      handle          // IN: PCR handle
103      )
104  {
105      UINT32      groupIndex;
106
107      if(PCRBelongsAuthGroup(handle, &groupIndex))
108      {
109          return &gc.pcrAuthValues.auth[groupIndex];
110      }
111      else
112      {
113          return NULL;
```

```
114         }
115     }
```

8.7.2.5 PCRGetAuthPolicy()

This function is used to access the authorization policy of a PCR. It sets *policy* to the authorization policy and returns the hash algorithm for policy If the PCR does not allow a policy, TPM_ALG_NULL is returned.

```
116     TPMI_ALG_HASH
117     PCRGetAuthPolicy(
118         TPMI_DH_PCR      handle,        // IN: PCR handle
119         TPM2B_DIGEST    *policy         // OUT: policy of PCR
120         )
121     {
122         UINT32           groupIndex;
123
124         if(PCRBelongsPolicyGroup(handle, &groupIndex))
125         {
126             *policy = gp.pcrPolicies.policy[groupIndex];
127             return gp.pcrPolicies.hashAlg[groupIndex];
128         }
129         else
130         {
131             policy->t.size = 0;
132             return TPM_ALG_NULL;
133         }
134     }
```

8.7.2.6 PCRSimStart()

This function is used to initialize the policies when a TPM is manufactured. This function would only be called in a manufacturing environment or in a TPM simulator.

```
135     void
136     PCRSimStart(
137         void
138         )
139     {
140         UINT32  i;
141     #if defined NUM_POLICY_PCR_GROUP && NUM_POLICY_PCR_GROUP > 0
142         for(i = 0; i < NUM_POLICY_PCR_GROUP; i++)
143         {
144             gp.pcrPolicies.hashAlg[i] = TPM_ALG_NULL;
145             gp.pcrPolicies.policy[i].t.size = 0;
146         }
147     #endif
148     #if defined NUM_AUTHVALUE_PCR_GROUP && NUM_AUTHVALUE_PCR_GROUP > 0
149         for(i = 0; i < NUM_AUTHVALUE_PCR_GROUP; i++)
150         {
151             gc.pcrAuthValues.auth[i].t.size = 0;
152         }
153     #endif
154         // We need to give an initial configuration on allocated PCR before
155         // receiving any TPM2_PCR_Allocate command to change this configuration
156         // When the simulation environment starts, we allocate all the PCRs
157         for(gp.pcrAllocated.count = 0; gp.pcrAllocated.count < HASH_COUNT;
158         gp.pcrAllocated.count++)
159         {

161                 = CryptHashGetAlgByIndex(gp.pcrAllocated.count);
162
163             gp.pcrAllocated.pcrSelections[gp.pcrAllocated.count].sizeofSelect
```

```
164                 = PCR_SELECT_MAX;
165             for(i = 0; i < PCR_SELECT_MAX; i++)
166                 gp.pcrAllocated.pcrSelections[gp.pcrAllocated.count].pcrSelect[i]
167                 = 0xFF;
168         }
169
170         // Store the initial configuration to NV
171         NV_SYNC_PERSISTENT(pcrPolicies);
172         NV_SYNC_PERSISTENT(pcrAllocated);
173
174         return;
175     }
```

8.7.2.7 GetSavedPcrPointer()

This function returns the address of an array of state saved PCR based on the hash algorithm.

Return Value	Meaning
NULL	no such algorithm
NULL	pointer to the 0th byte of the 0th PCR

```
176     static BYTE *
177     GetSavedPcrPointer(
178         TPM_ALG_ID       alg,           // IN: algorithm for bank
179         UINT32           pcrIndex       // IN: PCR index in PCR_SAVE
180         )
181     {
182         BYTE            *retVal;
183         switch(alg)
184         {
185     #if ALG_SHA1
186             case ALG_SHA1_VALUE:
187                 retVal = gc.pcrSave.sha1[pcrIndex];
188                 break;
189     #endif
190     #if ALG_SHA256
191             case ALG_SHA256_VALUE:
192                 retVal = gc.pcrSave.sha256[pcrIndex];
193                 break;
194     #endif
195     #if ALG_SHA384
196             case ALG_SHA384_VALUE:
197                 retVal = gc.pcrSave.sha384[pcrIndex];
198                 break;
199     #endif
200
201     #if ALG_SHA512
202             case ALG_SHA512_VALUE:
203                 retVal = gc.pcrSave.sha512[pcrIndex];
204                 break;
205     #endif
206     #if ALG_SM3_256
207             case ALG_SM3_256_VALUE:
208                 retVal = gc.pcrSave.sm3_256[pcrIndex];
209                 break;
210     #endif
211             default:
212                 FAIL(FATAL_ERROR_INTERNAL);
213         }
214         return retVal;
215     }
```

8.7.2.8 PcrIsAllocated()

This function indicates if a PCR number for the particular hash algorithm is allocated.

Return Value	Meaning
TRUE(1)	PCR is allocated
FALSE(0)	PCR is not allocated

```
216 BOOL
217 PcrIsAllocated(
218     UINT32          pcr,            // IN: The number of the PCR
219     TPMI_ALG_HASH   hashAlg         // IN: The PCR algorithm
220     )
221 {
222     UINT32              i;
223     BOOL                allocated = FALSE;
224
225     if(pcr < IMPLEMENTATION_PCR)
226     {
227         for(i = 0; i < gp.pcrAllocated.count; i++)
228         {
229             if(gp.pcrAllocated.pcrSelections[i].hash == hashAlg)
230             {
231                 if(((gp.pcrAllocated.pcrSelections[i].pcrSelect[pcr / 8])
232                     & (1 << (pcr % 8))) != 0)
233                     allocated = TRUE;
234                 else
235                     allocated = FALSE;
236                 break;
237             }
238         }
239     }
240     return allocated;
241 }
```

8.7.2.9 GetPcrPointer()

This function returns the address of an array of PCR based on the hash algorithm.

Return Value	Meaning
NULL	no such algorithm
NULL	pointer to the 0th byte of the 0th PCR

```
242 static BYTE *
243 GetPcrPointer(
244     TPM_ALG_ID      alg,            // IN: algorithm for bank
245     UINT32          pcrNumber       // IN: PCR number
246     )
247 {
248     static BYTE     *pcr = NULL;
249
250     if(!PcrIsAllocated(pcrNumber, alg))
251         return NULL;
252
253     switch(alg)
254     {
255 #if ALG_SHA1
256         case ALG_SHA1_VALUE:
257             pcr = s_pcrs[pcrNumber].sha1Pcr;
258             break;
```

273             break;
274 #endif
275 #if ALG_SM3_256
276         case ALG_SM3_256_VALUE:
277             pcr = s_pcrs[pcrNumber].sm3_256Pcr;
278             break;
279 #endif
280         default:
281             FAIL(FATAL_ERROR_INTERNAL);
282             break;
283     }
284     return pcr;
285 }
```

8.7.2.10 IsPcrSelected()

This function indicates if an indicated PCR number is selected by the bit map in *selection*.

Return Value	Meaning
TRUE(1)	PCR is selected
FALSE(0)	PCR is not selected

```
286 static BOOL
287 IsPcrSelected(
288     UINT32              pcr,            // IN: The number of the PCR
289     TPMS_PCR_SELECTION  *selection      // IN: The selection structure
290     )
291 {
292     BOOL                selected;
293     selected = (pcr < IMPLEMENTATION_PCR
294                 && ((selection->pcrSelect[pcr / 8]) & (1 << (pcr % 8))) != 0);
295     return selected;
296 }
```

8.7.2.11 FilterPcr()

This function modifies a PCR selection array based on the implemented PCR.

```
297 static void
298 FilterPcr(
299     TPMS_PCR_SELECTION  *selection      // IN: input PCR selection
300     )
301 {
302     UINT32      i;
303     TPMS_PCR_SELECTION      *allocated = NULL;
304
305     // If size of select is less than PCR_SELECT_MAX, zero the unspecified PCR
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
306     for(i = selection->sizeofSelect; i < PCR_SELECT_MAX; i++)
307         selection->pcrSelect[i] = 0;
308
309     // Find the internal configuration for the bank
310     for(i = 0; i < gp.pcrAllocated.count; i++)
311     {
312         if(gp.pcrAllocated.pcrSelections[i].hash == selection->hash)
313         {
314             allocated = &gp.pcrAllocated.pcrSelections[i];
315             break;
316         }
317     }
318
319     for(i = 0; i < selection->sizeofSelect; i++)
320     {
321         if(allocated == NULL)
322         {
323             // If the required bank does not exist, clear input selection
324             selection->pcrSelect[i] = 0;
325         }
326         else
327             selection->pcrSelect[i] &= allocated->pcrSelect[i];
328     }
329
330     return;
331 }
```

8.7.2.12 PcrDrtm()

This function does the DRTM and H-CRTM processing it is called from _TPM_Hash_End().

```
332 void
333 PcrDrtm(
334     const TPMI_DH_PCR        pcrHandle,      // IN: the index of the PCR to be
335                                              //     modified
336     const TPMI_ALG_HASH      hash,           // IN: the bank identifier
337     const TPM2B_DIGEST      *digest          // IN: the digest to modify the PCR
338     )
339 {
340     BYTE         *pcrData = GetPcrPointer(hash, pcrHandle);
341
342     if(pcrData != NULL)
343     {
344         // Rest the PCR to zeros
345         MemorySet(pcrData, 0, digest->t.size);
346
347         // if the TPM has not started, then set the PCR to 0...04 and then extend
348         if(!TPMIsStarted())
349         {
350             pcrData[digest->t.size - 1] = 4;
351         }
352         // Now, extend the value
353         PCRExtend(pcrHandle, hash, digest->t.size, (BYTE *)digest->t.buffer);
354     }
355 }
```

8.7.2.13 PCR_ClearAuth()

This function is used to reset the PCR authorization values. It is called on TPM2_Startup(CLEAR) and TPM2_Clear().

```
356 void
357 PCR_ClearAuth(
```

```
358      void
359      )
360  {
361  #if defined NUM_AUTHVALUE_PCR_GROUP && NUM_AUTHVALUE_PCR_GROUP > 0
362      int          j;
363      for(j = 0; j < NUM_AUTHVALUE_PCR_GROUP; j++)
364      {
365          gc.pcrAuthValues.auth[j].t.size = 0;
366      }
367  #endif
368  }
```

8.7.2.14 PCRStartup()

This function initializes the PCR subsystem at TPM2_Startup().

```
369  BOOL
370  PCRStartup(
371      STARTUP_TYPE     type,          // IN: startup type
372      BYTE             locality       // IN: startup locality
373      )
374  {
375      UINT32              pcr, j;
376      UINT32              saveIndex = 0;
377
378      g_pcrReConfig = FALSE;
379
380      // Don't test for SU_RESET because that should be the default when nothing
381      // else is selected
382      if(type != SU_RESUME && type != SU_RESTART)
383      {
384          // PCR generation counter is cleared at TPM_RESET
385          gr.pcrCounter = 0;
386      }
387
388      // Initialize/Restore PCR values
389      for(pcr = 0; pcr < IMPLEMENTATION_PCR; pcr++)
390      {
391          // On resume, need to know if this PCR had its state saved or not
392          UINT32      stateSaved;
393
394          if(type == SU_RESUME
395             &&  s_initAttributes[pcr].stateSave == SET)

488                         BYTE    *pcrSavedData;
489                         pcrSavedData
490                             = GetSavedPcrPointer(gp.pcrAllocated.pcrSelections[j].hash,
491                                                  saveIndex);
492                         MemoryCopy(pcrSavedData, pcrData, pcrSize);
493                     }
494                 }
495             }
496             saveIndex += stateSaved;
497         }
498
499         return;
500     }
```

8.7.2.16 PCRIsStateSaved()

This function indicates if the selected PCR is a PCR that is state saved on TPM2_Shutdown(STATE). The return value is based on PCR attributes.

Return Value	Meaning
TRUE(1)	PCR is state saved
FALSE(0)	PCR is not state saved

```
501     BOOL
502     PCRIsStateSaved(
503         TPMI_DH_PCR      handle          // IN: PCR handle to be extended
504         )
505     {
506         UINT32              pcr = handle - PCR_FIRST;
507
508         if(s_initAttributes[pcr].stateSave == SET)
509             return TRUE;
510         else
511             return FALSE;
512     }
```

8.7.2.17 PCRIsResetAllowed()

This function indicates if a PCR may be reset by the current command locality. The return value is based on PCR attributes, and not the PCR allocation.

Return Value	Meaning
TRUE(1)	TPM2_PCR_Reset() is allowed
FALSE(0)	TPM2_PCR_Reset() is not allowed

```
513     BOOL
514     PCRIsResetAllowed(
```

```
515     TPMI_DH_PCR      handle         // IN: PCR handle to be extended
516     )
517 {
518     UINT8                commandLocality;
519     UINT8                localityBits = 1;
520     UINT32               pcr = handle - PCR_FIRST;
521
522     // Check for the locality
523     commandLocality = _plat__LocalityGet();
524
525 #ifdef DRTM_PCR
526     // For a TPM that does DRTM, Reset is not allowed at locality 4
527     if(commandLocality == 4)
528         return FALSE;
529 #endif
530
531     localityBits = localityBits << commandLocality;
532     if((localityBits & s_initAttributes[pcr].resetLocality) == 0)
533         return FALSE;
534     else
535         return TRUE;
536 }
```

8.7.2.18 PCRChanged()

This function checks a PCR handle to see if the attributes for the PCR are set so that any change to the PCR causes an increment of the *pcrCounter*. If it does, then the function increments the counter. Will also bump the counter if the handle is zero which means that PCR 0 can not be in the TCB group. Bump on zero is used by TPM2_Clear().

```
537 void
538 PCRChanged(
539     TPM_HANDLE       pcrHandle      // IN: the handle of the PCR that changed.
540     )
541 {
542     // For the reference implementation, the only change that does not cause
543     // increment is a change to a PCR in the TCB group.
544     if((pcrHandle == 0) || !PCRBelongsTCBGroup(pcrHandle))
545     {
546         gr.pcrCounter++;
547         if(gr.pcrCounter == 0)
548             FAIL(FATAL_ERROR_COUNTER_OVERFLOW);
549     }
550 }
```

8.7.2.19 PCRIsExtendAllowed()

This function indicates a PCR may be extended at the current command locality. The return value is based on PCR attributes, and not the PCR allocation.

Return Value	Meaning
TRUE(1)	extend is allowed
FALSE(0)	extend is not allowed

```
551 BOOL
552 PCRIsExtendAllowed(
553     TPMI_DH_PCR      handle         // IN: PCR handle to be extended
554     )
555 {
556     UINT8                commandLocality;
```

```
557     UINT8               localityBits = 1;
558     UINT32              pcr = handle - PCR_FIRST;
559
560     // Check for the locality
561     commandLocality = _plat__LocalityGet();
562     localityBits = localityBits << commandLocality;
563     if((localityBits & s_initAttributes[pcr].extendLocality) == 0)
564         return FALSE;
565     else
566         return TRUE;
567 }
```

8.7.2.20 PCRExtend()

This function is used to extend a PCR in a specific bank.

```
568 void
569 PCRExtend(
570     TPMI_DH_PCR      handle,        // IN: PCR handle to be extended
571     TPMI_ALG_HASH    hash,          // IN: hash algorithm of PCR
572     UINT32           size,          // IN: size of data to be extended
573     BYTE            *data           // IN: data to be extended
574     )
575 {
576     BYTE                *pcrData;
577     HASH_STATE           hashState;
578     UINT16               pcrSize;
579
580     pcrData = GetPcrPointer(hash, handle - PCR_FIRST);
581
582     // Extend PCR if it is allocated
583     if(pcrData != NULL)
584     {
585         pcrSize = CryptHashGetDigestSize(hash);
586         CryptHashStart(&hashState, hash);
587         CryptDigestUpdate(&hashState, pcrSize, pcrData);
588         CryptDigestUpdate(&hashState, size, data);
589         CryptHashEnd(&hashState, pcrSize, pcrData);
590
591         // PCR has changed so update the pcrCounter if necessary
592         PCRChanged(handle);
593     }
594
595     return;
596 }
```

8.7.2.21 PCRComputeCurrentDigest()

This function computes the digest of the selected PCR.

As a side-effect, *selection* is modified so that only the implemented PCR will have their bits still set.

```
597 void
598 PCRComputeCurrentDigest(
599     TPMI_ALG_HASH        hashAlg,       // IN: hash algorithm to compute digest
600     TPML_PCR_SELECTION  *selection,     // IN/OUT: PCR selection (filtered on
601                                         //     output)
602     TPM2B_DIGEST        *digest         // OUT: digest
603     )
604 {
605     HASH_STATE                hashState;
606     TPMS_PCR_SELECTION       *select;
607     BYTE                     *pcrData;   // will point to a digest
```

```
608     UINT32                  pcrSize;
609     UINT32                  pcr;
610     UINT32                  i;
611
612     // Initialize the hash
613     digest->t.size = CryptHashStart(&hashState, hashAlg);
614     pAssert(digest->t.size > 0 && digest->t.size < UINT16_MAX);
615
616     // Iterate through the list of PCR selection structures
617     for(i = 0; i < selection->count; i++)
618     {
619         // Point to the current selection
620         select = &selection->pcrSelections[i]; // Point to the current selection
621         FilterPcr(select);      // Clear out the bits for unimplemented PCR
622
623         // Need the size of each digest
624         pcrSize = CryptHashGetDigestSize(selection->pcrSelections[i].hash);
625
626         // Iterate through the selection
627         for(pcr = 0; pcr < IMPLEMENTATION_PCR; pcr++)
628         {
629             if(IsPcrSelected(pcr, select))         // Is this PCR selected
630             {
631                 // Get pointer to the digest data for the bank
632                 pcrData = GetPcrPointer(selection->pcrSelections[i].hash, pcr);
633                 pAssert(pcrData != NULL);
634                 CryptDigestUpdate(&hashState, pcrSize, pcrData);  // add to digest
635             }
636         }
637     }
638     // Complete hash stack
639     CryptHashEnd2B(&hashState, &digest->b);
640
641     return;
642 }
```

8.7.2.22 PCRRead()

This function is used to read a list of selected PCR. If the requested PCR number exceeds the maximum number that can be output, the *selection* is adjusted to reflect the actual output PCR.

```
643 void
644 PCRRead(
645     TPML_PCR_SELECTION  *selection,     // IN/OUT: PCR selection (filtered on
646                                         //     output)
647     TPML_DIGEST         *digest,        // OUT: digest
648     UINT32              *pcrCounter     // OUT: the current value of PCR generation
649                                         //     number
650     )
651 {
652     TPMS_PCR_SELECTION      *select;
653     BYTE                    *pcrData;       // will point to a digest
654     UINT32                   pcr;
655     UINT32                   i;
656
657     digest->count = 0;
658
659     // Iterate through the list of PCR selection structures
660     for(i = 0; i < selection->count; i++)
661     {
662         // Point to the current selection
663         select = &selection->pcrSelections[i]; // Point to the current selection
664         FilterPcr(select);      // Clear out the bits for unimplemented PCR
665
```

```
666             // Iterate through the selection
667             for(pcr = 0; pcr < IMPLEMENTATION_PCR; pcr++)
668             {
669                 if(IsPcrSelected(pcr, select))          // Is this PCR selected
670                 {
671                     // Check if number of digest exceed upper bound
672                     if(digest->count > 7)
673                     {
674                         // Clear rest of the current select bitmap
675                         while(pcr < IMPLEMENTATION_PCR
676                                   // do not round up!
677                               && (pcr / 8) < select->sizeofSelect)
678                         {
679                             // do not round up!
680                             select->pcrSelect[pcr / 8] &= (BYTE)~(1 << (pcr % 8));
681                             pcr++;
682                         }
683                         // Exit inner loop
684                         break;
685                     }
686                     // Need the size of each digest
687                     digest->digests[digest->count].t.size =
688                         CryptHashGetDigestSize(selection->pcrSelections[i].hash);
689
690                     // Get pointer to the digest data for the bank
691                     pcrData = GetPcrPointer(selection->pcrSelections[i].hash, pcr);
692                     pAssert(pcrData != NULL);
693                     // Add to the data to digest
694                     MemoryCopy(digest->digests[digest->count].t.buffer,
695                                pcrData,
696                                digest->digests[digest->count].t.size);
697                     digest->count++;
698                 }
699             }
700             // If we exit inner loop because we have exceed the output upper bound
701             if(digest->count > 7 && pcr < IMPLEMENTATION_PCR)
702             {
703                 // Clear rest of the selection
704                 while(i < selection->count)
705                 {
706                     MemorySet(selection->pcrSelections[i].pcrSelect, 0,
707                               selection->pcrSelections[i].sizeofSelect);
708                     i++;
709                 }
710                 // exit outer loop
711                 break;
712             }
713         }
714
715         *pcrCounter = gr.pcrCounter;
716
717         return;
718     }
```

8.7.2.23 PCRAllocate()

This function is used to change the PCR allocation.

Error Returns	Meaning
TPM_RC_NO_RESULT	allocate failed
TPM_RC_PCR	improper allocation

```
719   TPM_RC
720   PCRAllocate(
721       TPML_PCR_SELECTION  *allocate,      // IN: required allocation
722       UINT32              *maxPCR,        // OUT: Maximum number of PCR
723       UINT32              *sizeNeeded,    // OUT: required space
724       UINT32              *sizeAvailable  // OUT: available space
725       )
726   {

798              }
799          }
800      }
801
802      if(!pcrDrtm || !pcrHcrtm)
803          return TPM_RC_PCR;
804
805      // In this particular implementation, we always have enough space to
806      // allocate PCR.  Different implementation may return a sizeAvailable less
807      // than the sizeNeed.
808      *sizeAvailable = sizeof(s_pcrs);
809
810      // Save the required allocation to NV.  Note that after NV is written, the
811      // PCR allocation in NV is no longer consistent with the RAM data
812      // gp.pcrAllocated.  The NV version reflect the allocate after next
813      // TPM_RESET, while the RAM version reflects the current allocation
814      NV_WRITE_PERSISTENT(pcrAllocated, newAllocate);
815
816      return TPM_RC_SUCCESS;
817  }
```

8.7.2.24 PCRSetValue()

This function is used to set the designated PCR in all banks to an initial value. The initial value is signed and will be sign extended into the entire PCR.

```
818  void
819  PCRSetValue(
820      TPM_HANDLE       handle,        // IN: the handle of the PCR to set
821      INT8             initialValue   // IN: the value to set
822      )
823  {
824      int              i;
825      UINT32           pcr = handle - PCR_FIRST;
826      TPMI_ALG_HASH    hash;
827      UINT16           digestSize;
828      BYTE            *pcrData;
829
830      // Iterate supported PCR bank algorithms to reset
831      for(i = 0; i < HASH_COUNT; i++)
832      {
833          hash = CryptHashGetAlgByIndex(i);
834          // Prevent runaway
835          if(hash == TPM_ALG_NULL)
```

```
836                 break;
837
838             // Get a pointer to the data
839             pcrData = GetPcrPointer(gp.pcrAllocated.pcrSelections[i].hash, pcr);
840
841             // If the PCR is allocated
842             if(pcrData != NULL)
843             {
844                 // And the size of the digest
845                 digestSize = CryptHashGetDigestSize(hash);
846
847                 // Set the LSO to the input value
848                 pcrData[digestSize - 1] = initialValue;
849
850                 // Sign extend
851                 if(initialValue >= 0)
852                     MemorySet(pcrData, 0, digestSize - 1);
853                 else
854                     MemorySet(pcrData, -1, digestSize - 1);
855             }
856         }
857 }
```

8.7.2.25 PCRResetDynamics

This function is used to reset a dynamic PCR to 0. This function is used in DRTM sequence.

```
858 void
859 PCRResetDynamics(
860     void
861     )
862 {
863     UINT32              pcr, i;
864
865     // Initialize PCR values
866     for(pcr = 0; pcr < IMPLEMENTATION_PCR; pcr++)
867     {
868         // Iterate each hash algorithm bank
869         for(i = 0; i < gp.pcrAllocated.count; i++)
870         {
871             BYTE    *pcrData;
872             UINT32  pcrSize;
873
874             pcrData = GetPcrPointer(gp.pcrAllocated.pcrSelections[i].hash, pcr);
875
876             if(pcrData != NULL)
877             {
878                 pcrSize =
879                     CryptHashGetDigestSize(gp.pcrAllocated.pcrSelections[i].hash);
880
881                 // Reset PCR
882                 // Any PCR can be reset by locality 4 should be reset to 0
883                 if((s_initAttributes[pcr].resetLocality & 0x10) != 0)
884                     MemorySet(pcrData, 0, pcrSize);
885             }
886         }
887     }
888     return;
889 }
```

8.7.2.26 PCRCapGetAllocation()

This function is used to get the current allocation of PCR banks.

Return Value	Meaning
YES	if the return count is 0
NO	if the return count is not 0

```
890  TPMI_YES_NO
891  PCRCapGetAllocation(
892      UINT32                 count,          // IN: count of return
893      TPML_PCR_SELECTION    *pcrSelection    // OUT: PCR allocation list
894      )
895  {
896      if(count == 0)
897      {
898          pcrSelection->count = 0;
899          return YES;
900      }
901      else
902      {
903          *pcrSelection = gp.pcrAllocated;
904          return NO;
905      }
906  }
```

8.7.2.27 PCRSetSelectBit()

This function sets a bit in a bitmap array.

```
907  static void
908  PCRSetSelectBit(
909      UINT32              pcr,            // IN: PCR number
910      BYTE               *bitmap          // OUT: bit map to be set
911      )
912  {
913      bitmap[pcr / 8] |= (1 << (pcr % 8));
914      return;
915  }
```

8.7.2.28 PCRGetProperty()

This function returns the selected PCR property.

Return Value	Meaning
TRUE(1)	the property type is implemented
FALSE(0)	the property type is not implemented

```
916  static BOOL
917  PCRGetProperty(
918      TPM_PT_PCR                 property,
919      TPMS_TAGGED_PCR_SELECT    *select
920      )
921  {
922      UINT32                  pcr;
923      UINT32                  groupIndex;
924
925      select->tag = property;
926      // Always set the bitmap to be the size of all PCR
927      select->sizeofSelect = (IMPLEMENTATION_PCR + 7) / 8;
928
929      // Initialize bitmap
```

 Copyright © TCG 2006-2020

```
930         MemorySet(select->pcrSelect, 0, select->sizeofSelect);
931
932         // Collecting properties
933         for(pcr = 0; pcr < IMPLEMENTATION_PCR; pcr++)
934         {

1052        return more;
1053    }
```

8.7.2.30 PCRCapGetHandles()

This function is used to get a list of handles of PCR, started from *handle*. If *handle* exceeds the maximum PCR handle range, an empty list will be returned and the return value will be NO.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
1054    TPMI_YES_NO
1055    PCRCapGetHandles(
1056        TPMI_DH_PCR      handle,        // IN: start handle
1057        UINT32           count,         // IN: count of returned handles
1058        TPML_HANDLE     *handleList     // OUT: list of handle
1059        )
1060    {
1061        TPMI_YES_NO     more = NO;
1062        UINT32          i;
1063
1064        pAssert(HandleGetType(handle) == TPM_HT_PCR);
1065
1066        // Initialize output handle list
1067        handleList->count = 0;
1068
1069        // The maximum count of handles we may return is MAX_CAP_HANDLES
1070        if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
1071
1072        // Iterate PCR handle range
1073        for(i = handle & HR_HANDLE_MASK; i <= PCR_LAST; i++)
1074        {
1075            if(handleList->count < count)
1076            {
1077                // If we have not filled up the return list, add this PCR
1078                // handle to it
1079                handleList->handle[handleList->count] = i + PCR_FIRST;
1080                handleList->count++;
1081            }
1082            else
1083            {
1084                // If the return list is full but we still have PCR handle
1085                // available, report this and stop iterating

8.8 PP.c

8.8.1 Introduction

This file contains the functions that support the physical presence operations of the TPM.

8.8.2 Includes

```
1   #include "Tpm.h"
```

8.8.3 Functions

8.8.3.1 PhysicalPresencePreInstall_Init()

This function is used to initialize the array of commands that always require confirmation with physical presence. The array is an array of bits that has a correspondence with the command code.

This command should only ever be executable in a manufacturing setting or in a simulation.

When set, these cannot be cleared.

```
2   void
3   PhysicalPresencePreInstall_Init(
4       void
5       )
6   {
7       COMMAND_INDEX        commandIndex;
8       // Clear all the PP commands
9       MemorySet(&gp.ppList, 0, sizeof(gp.ppList));
10
11      // Any command that is PP_REQUIRED should be SET
12      for(commandIndex = 0; commandIndex < COMMAND_COUNT; commandIndex++)
13      {
14          if(s_commandAttributes[commandIndex] & IS_IMPLEMENTED
15             &&  s_commandAttributes[commandIndex] & PP_REQUIRED)
16              SET_BIT(commandIndex, gp.ppList);
17      }
18      // Write PP list to NV
19      NV_SYNC_PERSISTENT(ppList);
20      return;
21  }
```

8.8.3.2 PhysicalPresenceCommandSet()

This function is used to set the indicator that a command requires PP confirmation.

```
22  void
23  PhysicalPresenceCommandSet(
24      TPM_CC           commandCode     // IN: command code
25      )
26  {
27      COMMAND_INDEX       commandIndex = CommandCodeToCommandIndex(commandCode);
28
29      // if the command isn't implemented, the do nothing
30      if(commandIndex == UNIMPLEMENTED_COMMAND_INDEX)
31          return;
32
33      // only set the bit if this is a command for which PP is allowed
34      if(s_commandAttributes[commandIndex] & PP_COMMAND)
```

```
35              SET_BIT(commandIndex, gp.ppList);
36          return;
37      }
```

8.8.3.3 PhysicalPresenceCommandClear()

This function is used to clear the indicator that a command requires PP confirmation.

```
38      void
39      PhysicalPresenceCommandClear(
40          TPM_CC              commandCode     // IN: command code
41          )
42      {
43          COMMAND_INDEX         commandIndex = CommandCodeToCommandIndex(commandCode);
44
45          // If the command isn't implemented, then don't do anything
46          if(commandIndex == UNIMPLEMENTED_COMMAND_INDEX)
47              return;
48
49          // Only clear the bit if the command does not require PP
50          if((s_commandAttributes[commandIndex] & PP_REQUIRED) == 0)
51              CLEAR_BIT(commandIndex, gp.ppList);
52
53          return;
54      }
```

8.8.3.4 PhysicalPresenceIsRequired()

This function indicates if PP confirmation is required for a command.

Return Value	Meaning
TRUE(1)	physical presence is required
FALSE(0)	physical presence is not required

```
55      BOOL
56      PhysicalPresenceIsRequired(
57          COMMAND_INDEX       commandIndex    // IN: command index
58          )
59      {
60          // Check the bit map.  If the bit is SET, PP authorization is required
61          return (TEST_BIT(commandIndex, gp.ppList));
62      }
```

8.8.3.5 PhysicalPresenceCapGetCCList()

This function returns a list of commands that require PP confirmation. The list starts from the first implemented command that has a command code that the same or greater than *commandCode*.

Return Value	Meaning
YES	if there are more command codes available
NO	all the available command codes have been returned

```
63      TPMI_YES_NO
64      PhysicalPresenceCapGetCCList(
65          TPM_CC              commandCode,    // IN: start command code
66          UINT32              count,          // IN: count of returned TPM_CC
67          TPML_CC            *commandList     // OUT: list of TPM_CC
```

 Copyright © TCG 2006-2020

```
68      )
69  {
70      TPMI_YES_NO     more = NO;
71      COMMAND_INDEX   commandIndex;
72
73      // Initialize output handle list
74      commandList->count = 0;
75
76      // The maximum count of command we may return is MAX_CAP_CC
77      if(count > MAX_CAP_CC) count = MAX_CAP_CC;
78
79      // Collect PP commands
80      for(commandIndex = GetClosestCommandIndex(commandCode);
81      commandIndex != UNIMPLEMENTED_COMMAND_INDEX;
82          commandIndex = GetNextCommandIndex(commandIndex))
83      {
84          if(PhysicalPresenceIsRequired(commandIndex))
85          {
86              if(commandList->count < count)
87              {
88                  // If we have not filled up the return list, add this command
89                  // code to it
90                  commandList->commandCodes[commandList->count]
91                      = GetCommandCode(commandIndex);
92                  commandList->count++;
93              }
94              else
95              {
96                  // If the return list is full but we still have PP command
97                  // available, report this and stop iterating
98                  more = YES;
99                  break;
100             }
101         }
102     }
103     return more;
104 }
```

8.9 Session.c

8.9.1 Introduction

The code in this file is used to manage the session context counter. The scheme implemented here is a "truncated counter". This scheme allows the TPM to not need TPM_SU_CLEAR for a very long period of time and still not have the context count for a session repeated.

The counter (*contextCounter*)in this implementation is a UINT64 but can be smaller. The "tracking array" (*contextArray*) only has 16-bits per context. The tracking array is the data that needs to be saved and restored across TPM_SU_STATE so that sessions are not lost when the system enters the sleep state. Also, when the TPM is active, the tracking array is kept in RAM making it important that the number of bytes for each entry be kept as small as possible.

The TPM prevents **collisions** of these truncated values by not allowing a *contextID* to be assigned if it would be the same as an existing value. Since the array holds 16 bits, after a context has been saved, an additional 2^16-1 contexts may be saved before the count would again match. The normal expectation is that the context will be flushed before its count value is needed again but it is always possible to have long-lived sessions.

The *contextID* is assigned when the context is saved (TPM2_ContextSave()). At that time, the TPM will compare the low-order 16 bits of *contextCounter* to the existing values in *contextArray* and if one matches, the TPM will return TPM_RC_CONTEXT_GAP (by construction, the entry that contains the matching value is the oldest context).

The expected remediation by the TRM is to load the oldest saved session context (the one found by the TPM), and save it. Since loading the oldest session also eliminates its *contextID* value from *contextArray*, there TPM will always be able to load and save the oldest existing context.

In the worst case, software may have to load and save several contexts in order to save an additional one. This should happen very infrequently.

When the TPM searches *contextArray* and finds that none of the *contextIDs* match the low-order 16-bits of *contextCount*, the TPM can copy the low bits to the *contextArray* associated with the session, and increment *contextCount*.

There is one entry in *contextArray* for each of the active sessions allowed by the TPM implementation. This array contains either a context count, an index, or a value indicating the slot is available (0).

The index into the *contextArray* is the handle for the session with the region selector byte of the session set to zero. If an entry in *contextArray* contains 0, then the corresponding handle may be assigned to a session. If the entry contains a value that is less than or equal to the number of loaded sessions for the TPM, then the array entry is the slot in which the context is loaded.

EXAMPLE: If the TPM allows 8 loaded sessions, then the slot numbers would be 1-8 and a *contextArrary* value in that range would represent the loaded session.

NOTE: When the TPM firmware determines that the array entry is for a loaded session, it will subtract 1 to create the zero-based slot number.

There is one significant corner case in this scheme. When the *contextCount* is equal to a value in the *contextArray*, the oldest session needs to be recycled or flushed. In order to recycle the session, it must be loaded. To be loaded, there must be an available slot. Rather than require that a spare slot be available all the time, the TPM will check to see if the *contextCount* is equal to some value in the *contextArray* when a session is created. This prevents the last session slot from being used when it is likely that a session will need to be recycled.

If a TPM with both 1.2 and 2.0 functionality uses this scheme for both 1.2 and 2.0 sessions, and the list of active contexts is read with TPM_GetCapabiltiy(), the TPM will create 32-bit representations of the list that contains 16-bit values (the TPM2_GetCapability() returns a list of handles for active sessions rather than

 Copyright © TCG 2006-2020

a list of *contextID*). The full *contextID* has high-order bits that are either the same as the current *contextCount* or one less. It is one less if the 16-bits of the *contextArray* has a value that is larger than the low-order 16 bits of *contextCount*.

8.9.2 Includes, Defines, and Local Variables

```
1   #define SESSION_C
2   #include "Tpm.h"
```

8.9.3 File Scope Function -- ContextIdSetOldest()

This function is called when the oldest *contextID* is being loaded or deleted. Once a saved context becomes the oldest, it stays the oldest until it is deleted.

Finding the oldest is a bit tricky. It is not just the numeric comparison of values but is dependent on the value of *contextCounter*.

Assume we have a small *contextArray* with 8, 4-bit values with values 1 and 2 used to indicate the loaded context slot number. Also assume that the array contains hex values of (0 0 1 0 3 0 9 F) and that the *contextCounter* is an 8-bit counter with a value of 0x37. Since the low nibble is 7, that means that values closest to but above 7 are older than values below it and, in this example, 9 is the oldest value.

Note if we subtract the counter value, from each slot that contains a saved *contextID* we get (- - - - B - 2 - 8) and the oldest entry is now easy to find because it has the lowest value.

```
3   static void
4   ContextIdSetOldest(
5       void
6       )
7   {
8       CONTEXT_SLOT    lowBits;
9       CONTEXT_SLOT    entry;
10      CONTEXT_SLOT    smallest = ((CONTEXT_SLOT)~0);  // Set to the maximum possible
11      UINT32  i;
12
13      // Set oldestSaveContext to a value indicating none assigned
14      s_oldestSavedSession = MAX_ACTIVE_SESSIONS + 1;
15
16      lowBits = (CONTEXT_SLOT)gr.contextCounter;
17      for(i = 0; i < MAX_ACTIVE_SESSIONS; i++)
18      {
19          entry = gr.contextArray[i];
20
21          // only look at entries that are saved contexts
22          if(entry > MAX_LOADED_SESSIONS)
23          {
24              // Use a less than or equal in case the oldest
25              // is brand new (= lowBits-1) and equal to our initial
26              // value for smallest.
27              if(((CONTEXT_SLOT)(entry - lowBits)) <= smallest)
28              {
29                  smallest = (entry - lowBits);
30                  s_oldestSavedSession = i;
31              }
32          }
33      }
34      // When we finish, either the s_oldestSavedSession still has its initial
35      // value, or it has the index of the oldest saved context.
36  }
```

8.9.4 Startup Function -- SessionStartup()

This function initializes the session subsystem on TPM2_Startup().

```
37  BOOL
38  SessionStartup(
39      STARTUP_TYPE     type
40      )
41  {
42      UINT32              i;
43
44      // Initialize session slots.  At startup, all the in-memory session slots
45      // are cleared and marked as not occupied
46      for(i = 0; i < MAX_LOADED_SESSIONS; i++)
47          s_sessions[i].occupied = FALSE;   // session slot is not occupied
48
49      // The free session slots the number of maximum allowed loaded sessions
50      s_freeSessionSlots = MAX_LOADED_SESSIONS;
51
52      // Initialize context ID data.  On a ST_SAVE or hibernate sequence, it will
53      // scan the saved array of session context counts, and clear any entry that
54      // references a session that was in memory during the state save since that
55      // memory was not preserved over the ST_SAVE.
56      if(type == SU_RESUME || type == SU_RESTART)
57      {
58          // On ST_SAVE we preserve the contexts that were saved but not the ones
59          // in memory
60          for(i = 0; i < MAX_ACTIVE_SESSIONS; i++)
61          {
62              // If the array value is unused or references a loaded session then
63              // that loaded session context is lost and the array entry is
64              // reclaimed.
65              if(gr.contextArray[i] <= MAX_LOADED_SESSIONS)
66                  gr.contextArray[i] = 0;
67          }
68          // Find the oldest session in context ID data and set it in
69          // s_oldestSavedSession
70          ContextIdSetOldest();
71      }
72      else
73      {
74          // For STARTUP_CLEAR, clear out the contextArray
75          for(i = 0; i < MAX_ACTIVE_SESSIONS; i++)
76              gr.contextArray[i] = 0;
77
78          // reset the context counter
79          gr.contextCounter = MAX_LOADED_SESSIONS + 1;
80
81          // Initialize oldest saved session
82          s_oldestSavedSession = MAX_ACTIVE_SESSIONS + 1;
83      }
84      return TRUE;
85  }
```

8.9.5 Access Functions

8.9.5.1 SessionIsLoaded()

This function test a session handle references a loaded session. The handle must have previously been checked to make sure that it is a valid handle for an authorization session.

 Copyright © TCG 2006-2020

NOTE: A PWAP authorization does not have a session.

Return Value	Meaning
TRUE(1)	session is loaded
FALSE(0)	session is not loaded

```
 86 BOOL
 87 SessionIsLoaded(
 88     TPM_HANDLE       handle          // IN: session handle
 89     )
 90 {
 91     pAssert(HandleGetType(handle) == TPM_HT_POLICY_SESSION
 92             || HandleGetType(handle) == TPM_HT_HMAC_SESSION);
 93
 94     handle = handle & HR_HANDLE_MASK;
 95
 96     // if out of range of possible active session, or not assigned to a loaded
 97     // session return false
 98     if(handle >= MAX_ACTIVE_SESSIONS
 99        || gr.contextArray[handle] == 0
100        || gr.contextArray[handle] > MAX_LOADED_SESSIONS)
101         return FALSE;
102
103     return TRUE;
104 }
```

8.9.5.2 SessionIsSaved()

This function test a session handle references a saved session. The handle must have previously been checked to make sure that it is a valid handle for an authorization session.

NOTE: A password authorization does not have a session.

This function requires that the handle be a valid session handle.

Return Value	Meaning
TRUE(1)	session is saved
FALSE(0)	session is not saved

```
105 BOOL
106 SessionIsSaved(
107     TPM_HANDLE       handle          // IN: session handle
108     )
109 {
110     pAssert(HandleGetType(handle) == TPM_HT_POLICY_SESSION
111             || HandleGetType(handle) == TPM_HT_HMAC_SESSION);
112
113     handle = handle & HR_HANDLE_MASK;
114     // if out of range of possible active session, or not assigned, or
115     // assigned to a loaded session, return false
116     if(handle >= MAX_ACTIVE_SESSIONS
117        || gr.contextArray[handle] == 0
118        || gr.contextArray[handle] <= MAX_LOADED_SESSIONS
119        )
120         return FALSE;
121
122     return TRUE;
123 }
```

8.9.5.3 SequenceNumberForSavedContextIsValid()

This function validates that the sequence number and handle value within a saved context are valid.

```
124 BOOL
125 SequenceNumberForSavedContextIsValid(
126     TPMS_CONTEXT    *context        // IN: pointer to a context structure to be
127                                     //     validated
128     )
129 {
130 #define MAX_CONTEXT_GAP ((UINT64)((CONTEXT_SLOT) ~0) + 1)
131
132     TPM_HANDLE           handle = context->savedHandle & HR_HANDLE_MASK;
133
134     if(// Handle must be with the range of active sessions
135        handle >= MAX_ACTIVE_SESSIONS
136        // the array entry must be for a saved context
137        || gr.contextArray[handle] <= MAX_LOADED_SESSIONS
138           // the array entry must agree with the sequence number
139        || gr.contextArray[handle] != (CONTEXT_SLOT)context->sequence
140           // the provided sequence number has to be less than the current counter
141        || context->sequence > gr.contextCounter
142           // but not so much that it could not be a valid sequence number
143        || gr.contextCounter - context->sequence > MAX_CONTEXT_GAP)
144         return FALSE;
145
146     return TRUE;
147 }
```

8.9.5.4 SessionPCRValueIsCurrent()

This function is used to check if PCR values have been updated since the last time they were checked in a policy session.

This function requires the session is loaded.

Return Value	Meaning
TRUE(1)	PCR value is current
FALSE(0)	PCR value is not current

```
148 BOOL
149 SessionPCRValueIsCurrent(
150     SESSION         *session        // IN: session structure
151     )
152 {
153     if(session->pcrCounter != 0
154        && session->pcrCounter != gr.pcrCounter
155        )
156         return FALSE;
157     else
158         return TRUE;
159 }
```

8.9.5.5 SessionGet()

This function returns a pointer to the session object associated with a session handle.

The function requires that the session is loaded.

```
160 SESSION *
```

 Copyright © TCG 2006-2020

```
161     SessionGet(
162         TPM_HANDLE          handle          // IN: session handle
163         )
164     {
165         size_t          slotIndex;
166         CONTEXT_SLOT    sessionIndex;
167
168         pAssert(HandleGetType(handle) == TPM_HT_POLICY_SESSION
169                 || HandleGetType(handle) == TPM_HT_HMAC_SESSION
170                 );
171
172         slotIndex = handle & HR_HANDLE_MASK;
173
174         pAssert(slotIndex < MAX_ACTIVE_SESSIONS);
175
176         // get the contents of the session array.  Because session is loaded, we
177         // should always get a valid sessionIndex
178         sessionIndex = gr.contextArray[slotIndex] - 1;
179
180         pAssert(sessionIndex < MAX_LOADED_SESSIONS);
181
182         return &s_sessions[sessionIndex].session;
183     }
```

8.9.6 Utility Functions

8.9.6.1 ContextIdSessionCreate()

This function is called when a session is created. It will check to see if the current gap would prevent a context from being saved. If so it will return TPM_RC_CONTEXT_GAP. Otherwise, it will try to find an open slot in *contextArray*, set *contextArray* to the slot.

This routine requires that the caller has determined the session array index for the session.

Error Returns	Meaning
TPM_RC_CONTEXT_GAP	can't assign a new *contextID* until the oldest saved session context is recycled
TPM_RC_SESSION_HANDLE	there is no slot available in the context array for tracking of this session context

```
184     static TPM_RC
185     ContextIdSessionCreate(
186         TPM_HANDLE      *handle,         // OUT: receives the assigned handle. This will
187                                          //     be an index that must be adjusted by the
188                                          //     caller according to the type of the
189                                          //     session created
190         UINT32           sessionIndex    // IN: The session context array entry that will
191                                          //     be occupied by the created session
192         )
193     {
194         pAssert(sessionIndex < MAX_LOADED_SESSIONS);
195
196         // check to see if creating the context is safe
197         // Is this going to be an assignment for the last session context
198         // array entry?  If so, then there will be no room to recycle the
199         // oldest context if needed.  If the gap is not at maximum, then
200         // it will be possible to save a context if it becomes necessary.
201         if(s_oldestSavedSession < MAX_ACTIVE_SESSIONS
202            && s_freeSessionSlots == 1)
203         {

225      return TPM_RC_SESSION_HANDLES;
226  }
```

8.9.6.2 SessionCreate()

This function does the detailed work for starting an authorization session. This is done in a support routine rather than in the action code because the session management may differ in implementations. This implementation uses a fixed memory allocation to hold sessions and a fixed allocation to hold the *contextID* for the saved contexts.

Error Returns	Meaning
TPM_RC_CONTEXT_GAP	need to recycle sessions
TPM_RC_SESSION_HANDLE	active session space is full
TPM_RC_SESSION_MEMORY	loaded session space is full

```
227  TPM_RC
228  SessionCreate(
229      TPM_SE            sessionType,    // IN: the session type
230      TPMI_ALG_HASH     authHash,       // IN: the hash algorithm
231      TPM2B_NONCE      *nonceCaller,    // IN: initial nonceCaller
232      TPMT_SYM_DEF     *symmetric,      // IN: the symmetric algorithm
233      TPMI_DH_ENTITY    bind,           // IN: the bind object
234      TPM2B_DATA       *seed,           // IN: seed data
235      TPM_HANDLE       *sessionHandle,  // OUT: the session handle
236      TPM2B_NONCE      *nonceTpm        // OUT: the session nonce
237      )
238  {
239      TPM_RC                result = TPM_RC_SUCCESS;

356         return TPM_RC_SUCCESS;
357     }
```

8.9.6.3 SessionContextSave()

This function is called when a session context is to be saved. The *contextID* of the saved session is returned. If no *contextID* can be assigned, then the routine returns TPM_RC_CONTEXT_GAP. If the function completes normally, the session slot will be freed.

This function requires that *handle* references a loaded session. Otherwise, it should not be called at the first place.

Error Returns	Meaning
TPM_RC_CONTEXT_GAP	a *contextID* could not be assigned
TPM_RC_TOO_MANY_CONTEXTS	the counter maxed out

```
358     TPM_RC
359     SessionContextSave(
360         TPM_HANDLE           handle,         // IN: session handle
361         CONTEXT_COUNTER     *contextID       // OUT: assigned contextID
362         )
363     {
364         UINT32                       contextIndex;
365         CONTEXT_SLOT                 slotIndex;
366
```

410           s_oldestSavedSession = contextIndex;
411
412       // Mark the session slot as unoccupied
413       s_sessions[slotIndex].occupied = FALSE;
414
415       // and indicate that there is an additional open slot
416       s_freeSessionSlots++;
417
418       return TPM_RC_SUCCESS;
419   }
```

8.9.6.4 SessionContextLoad()

This function is used to load a session from saved context. The session handle must be for a saved context.

If the gap is at a maximum, then the only session that can be loaded is the oldest session, otherwise TPM_RC_CONTEXT_GAP is returned.

This function requires that *handle* references a valid saved session.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

Error Returns	Meaning
TPM_RC_SESSION_MEMORY	no free session slots
TPM_RC_CONTEXT_GAP	the gap count is maximum and this is not the oldest saved context

```
420  TPM_RC
421  SessionContextLoad(
422      SESSION_BUF     *session,       // IN: session structure from saved context
423      TPM_HANDLE      *handle         // IN/OUT: session handle
424      )
425  {
426      UINT32              contextIndex;
427      CONTEXT_SLOT        slotIndex;
428
429      pAssert(HandleGetType(*handle) == TPM_HT_POLICY_SESSION
430              || HandleGetType(*handle) == TPM_HT_HMAC_SESSION);
431
432      // Don't bother looking if no openings
433      if(s_freeSessionSlots == 0)
434          return TPM_RC_SESSION_MEMORY;
435
436      // Find a free session slot to load the session
437      for(slotIndex = 0; slotIndex < MAX_LOADED_SESSIONS; slotIndex++)
438          if(s_sessions[slotIndex].occupied == FALSE) break;
439
440      // if no spot found, then this is an internal error
441      pAssert(slotIndex < MAX_LOADED_SESSIONS);
442
443      contextIndex = *handle & HR_HANDLE_MASK;   // extract the index
444
445      // If there is only one slot left, and the gap is at maximum, the only session
446      // context that we can safely load is the oldest one.
447      if(s_oldestSavedSession < MAX_ACTIVE_SESSIONS
448         && s_freeSessionSlots == 1
449         && (CONTEXT_SLOT)gr.contextCounter == gr.contextArray[s_oldestSavedSession]
450         && contextIndex != s_oldestSavedSession)
451          return TPM_RC_CONTEXT_GAP;
452
453      pAssert(contextIndex < MAX_ACTIVE_SESSIONS);
454
455      // set the contextArray value to point to the session slot where
456      // the context is loaded
457      gr.contextArray[contextIndex] = slotIndex + 1;
458
459      // if this was the oldest context, find the new oldest
460      if(contextIndex == s_oldestSavedSession)

464      MemoryCopy(&s_sessions[slotIndex].session, session, sizeof(SESSION));
465
466             // Set session slot as occupied
467      s_sessions[slotIndex].occupied = TRUE;
468
469      // Reduce the number of open spots
470      s_freeSessionSlots--;
471
472      return TPM_RC_SUCCESS;
473  }
```

8.9.6.5 SessionFlush()

This function is used to flush a session referenced by its handle. If the session associated with *handle* is loaded, the session array entry is marked as available.

This function requires that *handle* be a valid active session.

```
474 void
475 SessionFlush(
476     TPM_HANDLE       handle          // IN: loaded or saved session handle
477     )
478 {
479     CONTEXT_SLOT         slotIndex;
480     UINT32               contextIndex;    // Index into contextArray
481
482     pAssert((HandleGetType(handle) == TPM_HT_POLICY_SESSION
483              || HandleGetType(handle) == TPM_HT_HMAC_SESSION
484              )
485             && (SessionIsLoaded(handle) || SessionIsSaved(handle))
486             );
487
488          // Flush context ID of this session
489          // Convert handle to an index into the contextArray
490     contextIndex = handle & HR_HANDLE_MASK;
491
492     pAssert(contextIndex < sizeof(gr.contextArray) / sizeof(gr.contextArray[0]));
493
494     // Get the current contents of the array
495     slotIndex = gr.contextArray[contextIndex];
496
497     // Mark context array entry as available
498     gr.contextArray[contextIndex] = 0;
499
500     // Is this a saved session being flushed
501     if(slotIndex > MAX_LOADED_SESSIONS)
502     {
503         // Flushing the oldest session?
504         if(contextIndex == s_oldestSavedSession)
505             // If so, find a new value for oldest.
506             ContextIdSetOldest();
507     }
508     else
509     {
510         // Adjust slot index to point to session array index
511         slotIndex -= 1;
512
513         // Free session array index
514         s_sessions[slotIndex].occupied = FALSE;
515         s_freeSessionSlots++;
516     }
517
518     return;
519 }
```

8.9.6.6 SessionComputeBoundEntity()

This function computes the binding value for a session. The binding value for a reserved handle is the handle itself. For all the other entities, the *authValue* at the time of binding is included to prevent squatting. For those values, the Name and the *authValue* are concatenated into the bind buffer. If they will not both fit, the will be overlapped by XORing bytes. If XOR is required, the bind value will be full.

```
520 void
521 SessionComputeBoundEntity(
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
522      TPMI_DH_ENTITY       entityHandle,  // IN: handle of entity
523      TPM2B_NAME          *bind           // OUT: binding value
524      )
525  {
526      TPM2B_AUTH           auth;
527      BYTE                *pAuth = auth.t.buffer;
528      UINT16               i;
529
530      // Get name
531      EntityGetName(entityHandle, bind);
532
533  //    // The bound value of a reserved handle is the handle itself
534  //    if(bind->t.size == sizeof(TPM_HANDLE)) return;
535
536      // For all the other entities, concatenate the authorization value to the name.
537      // Get a local copy of the authorization value because some overlapping
538      // may be necessary.
539      EntityGetAuthValue(entityHandle, &auth);
540
541      // Make sure that the extra space is zeroed
542      MemorySet(&bind->t.name[bind->t.size], 0, sizeof(bind->t.name) - bind->t.size);
543      // XOR the authValue at the end of the name
544      for(i = sizeof(bind->t.name) - auth.t.size; i < sizeof(bind->t.name); i++)
545          bind->t.name[i] ^= *pAuth++;
546
547      // Set the bind value to the maximum size
548      bind->t.size = sizeof(bind->t.name);
549
550      return;
551  }
```

8.9.6.7 SessionSetStartTime()

This function is used to initialize the session timing

```
552  void
553  SessionSetStartTime(
554      SESSION         *session        // IN: the session to update
555      )
556  {
557      session->startTime = g_time;
558      session->epoch = g_timeEpoch;
559      session->timeout = 0;
560  }
```

8.9.6.8 SessionResetPolicyData()

This function is used to reset the policy data without changing the nonce or the start time of the session.

```
561  void
562  SessionResetPolicyData(
563      SESSION         *session        // IN: the session to reset
564      )
565  {
566      SESSION_ATTRIBUTES      oldAttributes;
567      pAssert(session != NULL);
568
569      // Will need later
570      oldAttributes = session->attributes;
571
572      // No command
573      session->commandCode = 0;
574
```

 Copyright © TCG 2006-2020

```
575         // No locality selected
576         MemorySet(&session->commandLocality, 0, sizeof(session->commandLocality));
577
578         // The cpHash size to zero
579         session->u1.cpHash.b.size = 0;
580
581         // No timeout
582         session->timeout = 0;
583
584         // Reset the pcrCounter
585         session->pcrCounter = 0;
586
587         // Reset the policy hash
588         MemorySet(&session->u2.policyDigest.t.buffer, 0,
589                   session->u2.policyDigest.t.size);
590
591         // Reset the session attributes
592         MemorySet(&session->attributes, 0, sizeof(SESSION_ATTRIBUTES));
593
594         // Restore the policy attributes
595         session->attributes.isPolicy = SET;
596         session->attributes.isTrialPolicy = oldAttributes.isTrialPolicy;
597
598         // Restore the bind attributes
599         session->attributes.isDaBound = oldAttributes.isDaBound;
600         session->attributes.isLockoutBound = oldAttributes.isLockoutBound;
601     }
```

8.9.6.9 SessionCapGetLoaded()

This function returns a list of handles of loaded session, started from input *handle*

Handle must be in valid loaded session handle range, but does not have to point to a loaded session.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
602     TPMI_YES_NO
603     SessionCapGetLoaded(
604         TPMI_SH_POLICY    handle,         // IN: start handle
605         UINT32            count,          // IN: count of returned handles
606         TPML_HANDLE      *handleList      // OUT: list of handle
607         )
608     {
609         TPMI_YES_NO     more = NO;
610         UINT32          i;
611
612         pAssert(HandleGetType(handle) == TPM_HT_LOADED_SESSION);
613
614         // Initialize output handle list
615         handleList->count = 0;
616
617         // The maximum count of handles we may return is MAX_CAP_HANDLES
618         if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
619
620         // Iterate session context ID slots to get loaded session handles
621         for(i = handle & HR_HANDLE_MASK; i < MAX_ACTIVE_SESSIONS; i++)
622         {
623             // If session is active
624             if(gr.contextArray[i] != 0)
625             {
626                 // If session is loaded
```

```
627             if(gr.contextArray[i] <= MAX_LOADED_SESSIONS)
628             {
629                 if(handleList->count < count)
630                 {
631                     SESSION         *session;
632
633                     // If we have not filled up the return list, add this
634                     // session handle to it
635                     // assume that this is going to be an HMAC session
636                     handle = i + HMAC_SESSION_FIRST;
637                     session = SessionGet(handle);
638                     if(session->attributes.isPolicy)
639                         handle = i + POLICY_SESSION_FIRST;
640                     handleList->handle[handleList->count] = handle;
641                     handleList->count++;
642                 }
643                 else
644                 {
645                     // If the return list is full but we still have loaded object
646                     // available, report this and stop iterating
647                     more = YES;
648                     break;
649                 }
650             }
651         }
652     }
653
654     return more;
655 }
```

8.9.6.10 SessionCapGetSaved()

This function returns a list of handles for saved session, starting at *handle*.

Handle must be in a valid handle range, but does not have to point to a saved session

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
656 TPMI_YES_NO
657 SessionCapGetSaved(
658     TPMI_SH_HMAC     handle,         // IN: start handle
659     UINT32           count,          // IN: count of returned handles
660     TPML_HANDLE     *handleList      // OUT: list of handle
661     )
662 {
663     TPMI_YES_NO     more = NO;
664     UINT32          i;
665
666 #ifdef  TPM_HT_SAVED_SESSION
667     pAssert(HandleGetType(handle) == TPM_HT_SAVED_SESSION);
668 #else
669     pAssert(HandleGetType(handle) == TPM_HT_ACTIVE_SESSION);
670 #endif
671
672     // Initialize output handle list
673     handleList->count = 0;
674
675     // The maximum count of handles we may return is MAX_CAP_HANDLES
676     if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
677
678     // Iterate session context ID slots to get loaded session handles
```

```
679         for(i = handle & HR_HANDLE_MASK; i < MAX_ACTIVE_SESSIONS; i++)
680         {
681             // If session is active
682             if(gr.contextArray[i] != 0)
683             {
684                 // If session is saved
685                 if(gr.contextArray[i] > MAX_LOADED_SESSIONS)
686                 {
687                     if(handleList->count < count)
688                     {
689                         // If we have not filled up the return list, add this
690                         // session handle to it
691                         handleList->handle[handleList->count] = i + HMAC_SESSION_FIRST;
692                         handleList->count++;
693                     }
694                     else
695                     {
696                         // If the return list is full but we still have loaded object
697                         // available, report this and stop iterating
698                         more = YES;
699                         break;
700                     }
701                 }
702             }
703         }
704
705         return more;
706     }
```

8.9.6.11 SessionCapGetLoadedNumber()

This function return the number of authorization sessions currently loaded into TPM RAM.

```
707     UINT32
708     SessionCapGetLoadedNumber(
709         void
710         )
711     {
712         return MAX_LOADED_SESSIONS - s_freeSessionSlots;
713     }
```

8.9.6.12 SessionCapGetLoadedAvail()

This function returns the number of additional authorization sessions, of any type, that could be loaded into TPM RAM.

NOTE: In other implementations, this number may just be an estimate. The only requirement for the estimate is, if it is one or more, then at least one session must be loadable.

```
714     UINT32
715     SessionCapGetLoadedAvail(
716         void
717         )
718     {
719         return s_freeSessionSlots;
720     }
```

8.9.6.13 SessionCapGetActiveNumber()

This function returns the number of active authorization sessions currently being tracked by the TPM.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
721  UINT32
722  SessionCapGetActiveNumber(
723      void
724      )
725  {
726      UINT32              i;
727      UINT32              num = 0;
728
729      // Iterate the context array to find the number of non-zero slots
730      for(i = 0; i < MAX_ACTIVE_SESSIONS; i++)
731      {
732          if(gr.contextArray[i] != 0) num++;
733      }
734
735      return num;
736  }
```

8.9.6.14 SessionCapGetActiveAvail()

This function returns the number of additional authorization sessions, of any type, that could be created. This not the number of slots for sessions, but the number of additional sessions that the TPM is capable of tracking.

```
737  UINT32
738  SessionCapGetActiveAvail(
739      void
740      )
741  {
742      UINT32              i;
743      UINT32              num = 0;
744
745      // Iterate the context array to find the number of zero slots
746      for(i = 0; i < MAX_ACTIVE_SESSIONS; i++)
747      {
748          if(gr.contextArray[i] == 0) num++;
749      }
750
751      return num;
752  }
```

8.10 Time.c

8.10.1 Introduction

This file contains the functions relating to the TPM's time functions including the interface to the implementation-specific time functions.

8.10.2 Includes

```
1   #include "Tpm.h"
2   #include "PlatformClock.h"
```

8.10.3 Functions

8.10.3.1 TimePowerOn()

This function initialize time info at _TPM_Init().

This function is called at _TPM_Init() so that the TPM time can start counting as soon as the TPM comes out of reset and doesn't have to wait until TPM2_Startup() in order to begin the new time epoch. This could be significant for systems that could get powered up but not run any TPM commands for some period of time.

```
3   void
4   TimePowerOn(
5       void
6       )
7   {
8       g_time = _plat__TimerRead();
9   }
```

8.10.3.2 TimeNewEpoch()

This function does the processing to generate a new time epoch nonce and set NV for update. This function is only called when NV is known to be available and the clock is running. The epoch is updated to persistent data.

```
10  static void
11  TimeNewEpoch(
12      void
13      )
14  {
15  #if CLOCK_STOPS
16      CryptRandomGenerate(sizeof(CLOCK_NONCE), (BYTE *)&g_timeEpoch);
17  #else
18      // if the epoch is kept in NV, update it.
19      gp.timeEpoch++;
20      NV_SYNC_PERSISTENT(timeEpoch);
21  #endif
22      // Clean out any lingering state
23      _plat__TimerWasStopped();
24  }
```

8.10.3.3 TimeStartup()

This function updates the *resetCount* and *restartCount* components of TPMS_CLOCK_INFO structure at TPM2_Startup().

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

This function will deal with the deferred creation of a new epoch. TimeUpdateToCurrent() will not start a new epoch even if one is due when TPM_Startup() has not been run. This is because the state of NV is not known until startup completes. When Startup is done, then it will create the epoch nonce to complete the initializations by calling this function.

```
25  BOOL
26  TimeStartup(
27      STARTUP_TYPE      type              // IN: start up type
28      )
29  {
30      NOT_REFERENCED(type);
31      // If the previous cycle is orderly shut down, the value of the safe bit
32      // the same as previously saved.  Otherwise, it is not safe.
33      if(!NV_IS_ORDERLY)
34          go.clockSafe = NO;
35      return TRUE;
36  }
```

8.10.3.4 TimeClockUpdate()

This function updates go.clock. If *newTime* requires an update of NV, then NV is checked for availability. If it is not available or is rate limiting, then go.clock is not updated and the function returns an error. If *newTime* would not cause an NV write, then go.clock is updated. If an NV write occurs, then go.safe is SET.

```
37  void
38  TimeClockUpdate(
39      UINT64            newTime     // IN: New time value in mS.
40      )
41  {
42  #define CLOCK_UPDATE_MASK  ((1ULL << NV_CLOCK_UPDATE_INTERVAL)- 1)
43
44      // Check to see if the update will cause a need for an nvClock update
45      if((newTime | CLOCK_UPDATE_MASK) > (go.clock | CLOCK_UPDATE_MASK))
46      {
47          pAssert(g_NvStatus == TPM_RC_SUCCESS);
48
49          // Going to update the NV time state so SET the safe flag
50          go.clockSafe = YES;
51
52          // update the time
53          go.clock = newTime;
54
55          NvWrite(NV_ORDERLY_DATA, sizeof(go), &go);
56      }
57      else
58          // No NV update needed so just update
59          go.clock = newTime;
60
61  }
```

8.10.3.5 TimeUpdate()

This function is used to update the time and clock values. If the TPM has run TPM2_Startup(), this function is called at the start of each command. If the TPM has not run TPM2_Startup(), this is called from TPM2_Startup() to get the clock values initialized. It is not called on command entry because, in this implementation, the go structure is not read from NV until TPM2_Startup(). The reason for this is that the initialization code (_TPM_Init()) may run before NV is accessible.

```
62  void
63  TimeUpdate(
```

```
64       void
65       )
66   {
67       UINT64          elapsed;
68   //
69       // Make sure that we consume the current _plat__TimerWasStopped() state.
70      if(_plat__TimerWasStopped())
71       {
72           TimeNewEpoch();
73       }
74       // Get the difference between this call and the last time we updated the tick
75       // timer.
76       elapsed = _plat__TimerRead() - g_time;
77       // Don't read +
78       g_time += elapsed;
79
80       // Don't need to check the result because it has to be success because have
81       // already checked that NV is available.
82       TimeClockUpdate(go.clock + elapsed);
83
84       // Call self healing logic for dictionary attack parameters
85       DASelfHeal();
86   }
```

8.10.3.6 TimeUpdateToCurrent()

This function updates the *Time* and *Clock* in the global TPMS_TIME_INFO structure.

In this implementation, *Time* and *Clock* are updated at the beginning of each command and the values are unchanged for the duration of the command.

Because *Clock* updates may require a write to NV memory, *Time* and *Clock* are not allowed to advance if NV is not available. When clock is not advancing, any function that uses *Clock* will fail and return TPM_RC_NV_UNAVAILABLE or TPM_RC_NV_RATE.

This implementation does not do rate limiting. If the implementation does do rate limiting, then the *Clock* update should not be inhibited even when doing rate limiting.

```
87   void
88   TimeUpdateToCurrent(
89       void
90   )
91   {
92       // Can't update time during the dark interval or when rate limiting so don't
93       // make any modifications to the internal clock value. Also, defer any clock
94       // processing until TPM has run TPM2_Startup()
95       if(!NV_IS_AVAILABLE || !TPMIsStarted())
96           return;
97
98       TimeUpdate();
99   }
```

8.10.3.7 TimeSetAdjustRate()

This function is used to perform rate adjustment on *Time* and *Clock*.

```
100  void
101  TimeSetAdjustRate(
102      TPM_CLOCK_ADJUST     adjust          // IN: adjust constant
103      )
104  {
105      switch(adjust)
106      {
```

```
107             case TPM_CLOCK_COARSE_SLOWER:
108                 _plat__ClockAdjustRate(CLOCK_ADJUST_COARSE);
109                 break;
110             case TPM_CLOCK_COARSE_FASTER:
111                 _plat__ClockAdjustRate(-CLOCK_ADJUST_COARSE);
112                 break;
113             case TPM_CLOCK_MEDIUM_SLOWER:
114                 _plat__ClockAdjustRate(CLOCK_ADJUST_MEDIUM);
115                 break;
116             case TPM_CLOCK_MEDIUM_FASTER:
117                 _plat__ClockAdjustRate(-CLOCK_ADJUST_MEDIUM);
118                 break;
119             case TPM_CLOCK_FINE_SLOWER:
120                 _plat__ClockAdjustRate(CLOCK_ADJUST_FINE);
121                 break;
122             case TPM_CLOCK_FINE_FASTER:
123                 _plat__ClockAdjustRate(-CLOCK_ADJUST_FINE);
124                 break;
125             case TPM_CLOCK_NO_CHANGE:
126                 break;
127             default:
128                 FAIL(FATAL_ERROR_INTERNAL);
129                 break;
130         }
131
132         return;
133     }
```

8.10.3.8 TimeGetMarshaled()

This function is used to access TPMS_TIME_INFO in canonical form. The function collects the time information and marshals it into *dataBuffer* and returns the marshaled size

```
134     UINT16
135     TimeGetMarshaled(
136         TIME_INFO       *dataBuffer     // OUT: result buffer
137         )
138     {
139         TPMS_TIME_INFO      timeInfo;
140
141         // Fill TPMS_TIME_INFO structure
142         timeInfo.time = g_time;
143         TimeFillInfo(&timeInfo.clockInfo);
144
145         // Marshal TPMS_TIME_INFO to canonical form
146         return TPMS_TIME_INFO_Marshal(&timeInfo, (BYTE **)&dataBuffer, NULL);
147     }
```

8.10.3.9 TimeFillInfo

This function gathers information to fill in a TPMS_CLOCK_INFO structure.

```
148     void
149     TimeFillInfo(
150         TPMS_CLOCK_INFO     *clockInfo
151         )
152     {
153         clockInfo->clock = go.clock;
154         clockInfo->resetCount = gp.resetCount;
155         clockInfo->restartCount = gr.restartCount;
156
157         // If NV is not available, clock stopped advancing and the value reported is
158         // not "safe".
```

```
159     if(NV_IS_AVAILABLE)
160         clockInfo->safe = go.clockSafe;
161     else
162         clockInfo->safe = NO;
163
164     return;
165 }
```

9.1.3 AlgorithmCapGetImplemented()

This function is used by TPM2_GetCapability() to return a list of the implemented algorithms.

Return Value	Meaning
YES	more algorithms to report
NO	no more algorithms to report

```
119 TPMI_YES_NO
120 AlgorithmCapGetImplemented(
121     TPM_ALG_ID                      algID,      // IN: the starting algorithm ID
122     UINT32                          count,      // IN: count of returned algorithms
123     TPML_ALG_PROPERTY              *algList     // OUT: algorithm list
124     )
125 {
126     TPMI_YES_NO     more = NO;
127     UINT32          i;
128     UINT32          algNum;
129
130     // initialize output algorithm list
131     algList->count = 0;
132
133     // The maximum count of algorithms we may return is MAX_CAP_ALGS.
134     if(count > MAX_CAP_ALGS)
135         count = MAX_CAP_ALGS;
136
137     // Compute how many algorithms are defined in s_algorithms array.
138     algNum = sizeof(s_algorithms) / sizeof(s_algorithms[0]);
139
140     // Scan the implemented algorithm list to see if there is a match to 'algID'.
141     for(i = 0; i < algNum; i++)
142     {
143         // If algID is less than the starting algorithm ID, skip it
144         if(s_algorithms[i].algID < algID)
145             continue;
146         if(algList->count < count)
147         {
148             // If we have not filled up the return list, add more algorithms
149             // to it
150             algList->algProperties[algList->count].alg = s_algorithms[i].algID;
151             algList->algProperties[algList->count].algProperties =
152                 s_algorithms[i].attributes;
153             algList->count++;
154         }
155         else
156         {
157             // If the return list is full but we still have algorithms
158             // available, report this and stop scanning.
159             more = YES;
160             break;
161         }
162     }
163
164     return more;
165 }
```

9.1.4 AlgorithmGetImplementedVector()

This function returns the bit vector of the implemented algorithms.

```
166 LIB_EXPORT
167 void
168 AlgorithmGetImplementedVector(
169     ALGORITHM_VECTOR    *implemented    // OUT: the implemented bits are SET
170     )
171 {
172     int                         index;
173
174     // Nothing implemented until we say it is
175     MemorySet(implemented, 0, sizeof(ALGORITHM_VECTOR));
176
177     for(index = (sizeof(s_algorithms) / sizeof(s_algorithms[0])) - 1;
178     index >= 0;
179         index--)
180         SET_BIT(s_algorithms[index].algID, *implemented);
181     return;
182 }
```

9.2 Bits.c

9.2.1 Introduction

This file contains bit manipulation routines. They operate on bit arrays.

The 0th bit in the array is the right-most bit in the 0th octet in the array.

NOTE: If pAssert() is defined, the functions will assert if the indicated bit number is outside of the range of *bArray*. How the assert is handled is implementation dependent.

9.2.2 Includes

```
1   #include "Tpm.h"
```

9.2.3 Functions

9.2.3.1 TestBit()

This function is used to check the setting of a bit in an array of bits.

Return Value	Meaning
TRUE(1)	bit is set
FALSE(0)	bit is not set

```
2   BOOL
3   TestBit(
4       unsigned int     bitNum,         // IN: number of the bit in 'bArray'
5       BYTE            *bArray,         // IN: array containing the bits
6       unsigned int     bytesInArray    // IN: size in bytes of 'bArray'
7       )
8   {
9       pAssert(bytesInArray > (bitNum >> 3));
10      return((bArray[bitNum >> 3] & (1 << (bitNum & 7))) != 0);
11  }
```

9.2.3.2 SetBit()

This function will set the indicated bit in *bArray*.

```
12  void
13  SetBit(
14      unsigned int     bitNum,         // IN: number of the bit in 'bArray'
15      BYTE            *bArray,         // IN: array containing the bits
16      unsigned int     bytesInArray    // IN: size in bytes of 'bArray'
17      )
18  {
19      pAssert(bytesInArray > (bitNum >> 3));
20      bArray[bitNum >> 3] |= (1 << (bitNum & 7));
21  }
```

9.2.3.3 ClearBit()

This function will clear the indicated bit in *bArray*.

```
22  void
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
23  ClearBit(
24      unsigned int      bitNum,        // IN: number of the bit in 'bArray'.
25      BYTE             *bArray,        // IN: array containing the bits
26      unsigned int      bytesInArray   // IN: size in bytes of 'bArray'
27      )
28  {
29      pAssert(bytesInArray > (bitNum >> 3));
30      bArray[bitNum >> 3] &= ~(1 << (bitNum & 7));
31  }
```

9.3 CommandCodeAttributes.c

9.3.1 Introduction

This file contains the functions for testing various command properties.

9.3.2 Includes and Defines

```
1   #include "Tpm.h"
2   #include "CommandCodeAttributes_fp.h"
```

Set the default value for CC_VEND if not already set

```
3   #ifndef CC_VEND
4   #define     CC_VEND     (TPM_CC)(0x20000000)
5   #endif
6   typedef UINT16          ATTRIBUTE_TYPE;
```

The following file is produced from the command tables in part 3 of the specification. It defines the attributes for each of the commands.

NOTE: This file is currently produced by an automated process. Files produced from Part 2 or Part 3 tables through automated processes are not included in the specification so that there is no ambiguity about the table containing the information being the normative definition.

```
7   #define _COMMAND_CODE_ATTRIBUTES_
8   #include    "CommandAttributeData.h"
```

9.3.3 Command Attribute Functions

9.3.3.1 NextImplementedIndex()

This function is used when the lists are not compressed. In a compressed list, only the implemented commands are present. So, a search might find a value but that value may not be implemented. This function checks to see if the input *commandIndex* points to an implemented command and, if not, it searches upwards until it finds one. When the list is compressed, this function gets defined as a no-op.

Return Value	Meaning
UNIMPLEMENTED_COMMAND_INDEX	command is not implemented
other	index of the command

```
9   #if !COMPRESSED_LISTS
10  static COMMAND_INDEX
11  NextImplementedIndex(
12      COMMAND_INDEX       commandIndex
13      )
14  {
15      for(;commandIndex < COMMAND_COUNT; commandIndex++)
16      {
17          if(s_commandAttributes[commandIndex] & IS_IMPLEMENTED)
18              return commandIndex;
19      }
20      return UNIMPLEMENTED_COMMAND_INDEX;
21  }
22  #else
23  #define NextImplementedIndex(x)  (x)
24  #endif
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

9.3.3.2 GetClosestCommandIndex()

This function returns the command index for the command with a value that is equal to or greater than the input value

Return Value	Meaning
UNIMPLEMENTED_COMMAND_INDEX	command is not implemented
other	index of a command

```
25  COMMAND_INDEX
26  GetClosestCommandIndex(
27      TPM_CC            commandCode    // IN: the command code to start at
28      )
29  {
30      BOOL                vendor = (commandCode & CC_VEND) != 0;
31      COMMAND_INDEX       searchIndex = (COMMAND_INDEX)commandCode;
32
33      // The commandCode is a UINT32 and the search index is UINT16. We are going to
34      // search for a match but need to make sure that the commandCode value is not
35      // out of range. To do this, need to clear the vendor bit of the commandCode
36      // (if set) and compare the result to the 16-bit searchIndex value. If it is
37      // out of range, indicate that the command is not implemented
38      if((commandCode & ~CC_VEND) != searchIndex)
39          return UNIMPLEMENTED_COMMAND_INDEX;
40
41      // if there is at least one vendor command, the last entry in the array will
42      // have the v bit set. If the input commandCode is larger than the last
43      // vendor-command, then it is out of range.
44      if(vendor)
45      {
46  #if VENDOR_COMMAND_ARRAY_SIZE > 0
47          COMMAND_INDEX       commandIndex;
48          COMMAND_INDEX       min;
49          COMMAND_INDEX       max;

176     #endif
177         }
178     }
```

9.3.3.3 CommandCodeToComandIndex()

This function returns the index in the various attributes arrays of the command.

Return Value	Meaning
UNIMPLEMENTED_COMMAND_INDEX	command is not implemented
other	index of the command

```
179     COMMAND_INDEX
180     CommandCodeToCommandIndex(
181         TPM_CC          commandCode     // IN: the command code to look up
182         )
183     {
184         // Extract the low 16-bits of the command code to get the starting search index
185         COMMAND_INDEX       searchIndex = (COMMAND_INDEX)commandCode;
186         BOOL                vendor = (commandCode & CC_VEND) != 0;
187         COMMAND_INDEX       commandIndex;
188     #if !COMPRESSED_LISTS
189         if(!vendor)
190         {
191             commandIndex = searchIndex - (COMMAND_INDEX)s_ccAttr[0].commandIndex;
192             // Check for out of range or unimplemented.
193             // Note, since a COMMAND_INDEX is unsigned, if searchIndex is smaller than
194             // the lowest value of command, it will become a 'negative' number making
195             // it look like a large unsigned number, this will cause it to fail
196             // the unsigned check below.
197             if(commandIndex >= LIBRARY_COMMAND_ARRAY_SIZE
```

```
198                 || (s_commandAttributes[commandIndex] & IS_IMPLEMENTED) == 0)
199                 return UNIMPLEMENTED_COMMAND_INDEX;
200             return commandIndex;
201         }
202     #endif
203         // Need this code for any vendor code lookup or for compressed lists
204         commandIndex = GetClosestCommandIndex(commandCode);
205
206         // Look at the returned value from get closest. If it isn't the one that was
207         // requested, then the command is not implemented.
208         if(commandIndex != UNIMPLEMENTED_COMMAND_INDEX)
209         {
210             if((GET_ATTRIBUTE(s_ccAttr[commandIndex], TPMA_CC, commandIndex)
211                 != searchIndex)
212                || (IS_ATTRIBUTE(s_ccAttr[commandIndex], TPMA_CC, V)) != vendor)
213                 commandIndex = UNIMPLEMENTED_COMMAND_INDEX;
214         }
215         return commandIndex;
216     }
```

9.3.3.4 GetNextCommandIndex()

This function returns the index of the next implemented command.

Return Value	Meaning
UNIMPLEMENTED_COMMAND_INDEX	no more implemented commands
other	the index of the next implemented command

```
217     COMMAND_INDEX
218     GetNextCommandIndex(
219         COMMAND_INDEX     commandIndex    // IN: the starting index
220         )
221     {
222         while(++commandIndex < COMMAND_COUNT)
223         {
224     #if !COMPRESSED_LISTS
225             if(s_commandAttributes[commandIndex] & IS_IMPLEMENTED)
226     #endif
227                 return commandIndex;
228         }
229         return UNIMPLEMENTED_COMMAND_INDEX;
230     }
```

9.3.3.5 GetCommandCode()

This function returns the *commandCode* associated with the command index

```
231     TPM_CC
232     GetCommandCode(
233         COMMAND_INDEX     commandIndex    // IN: the command index
234         )
235     {
236         TPM_CC            commandCode = GET_ATTRIBUTE(s_ccAttr[commandIndex],
237                                                       TPMA_CC, commandIndex);
238         if(IS_ATTRIBUTE(s_ccAttr[commandIndex], TPMA_CC, V))
239             commandCode += CC_VEND;
240         return commandCode;
241     }
```

9.3.3.6 CommandAuthRole()

This function returns the authorization role required of a handle.

Return Value	Meaning
AUTH_NONE	no authorization is required
AUTH_USER	user role authorization is required
AUTH_ADMIN	admin role authorization is required
AUTH_DUP	duplication role authorization is required

```
242 AUTH_ROLE
243 CommandAuthRole(
244     COMMAND_INDEX      commandIndex,  // IN: command index
245     UINT32             handleIndex    // IN: handle index (zero based)
246     )
247 {
248     if(0 == handleIndex)
249     {
250         // Any authorization role set?
251         COMMAND_ATTRIBUTES  properties = s_commandAttributes[commandIndex];
252
253         if(properties & HANDLE_1_USER)
254             return AUTH_USER;
255         if(properties & HANDLE_1_ADMIN)
256             return AUTH_ADMIN;
257         if(properties & HANDLE_1_DUP)
258             return AUTH_DUP;
259     }
260     else if(1 == handleIndex)
261     {
262         if(s_commandAttributes[commandIndex] & HANDLE_2_USER)
263             return AUTH_USER;
264     }
265     return AUTH_NONE;
266 }
```

9.3.3.7 EncryptSize()

This function returns the size of the decrypt size field. This function returns 0 if encryption is not allowed

Return Value	Meaning
0	encryption not allowed
2	size field is two bytes
4	size field is four bytes

```
267 int
268 EncryptSize(
269     COMMAND_INDEX      commandIndex   // IN: command index
270     )
271 {
272     return ((s_commandAttributes[commandIndex] & ENCRYPT_2) ? 2 :
273             (s_commandAttributes[commandIndex] & ENCRYPT_4) ? 4 : 0);
274 }
```

 Copyright © TCG 2006-2020

9.3.3.8 DecryptSize()

This function returns the size of the decrypt size field. This function returns 0 if decryption is not allowed

Return Value	Meaning
0	encryption not allowed
2	size field is two bytes
4	size field is four bytes

```
275 int
276 DecryptSize(
277     COMMAND_INDEX    commandIndex   // IN: command index
278     )
279 {
280     return ((s_commandAttributes[commandIndex] & DECRYPT_2) ? 2 :
281             (s_commandAttributes[commandIndex] & DECRYPT_4) ? 4 : 0);
282 }
```

9.3.3.9 IsSessionAllowed()

This function indicates if the command is allowed to have sessions.

This function must not be called if the command is not known to be implemented.

Return Value	Meaning
TRUE(1)	session is allowed with this command
FALSE(0)	session is not allowed with this command

```
283 BOOL
284 IsSessionAllowed(
285     COMMAND_INDEX    commandIndex   // IN: the command to be checked
286     )
287 {
288     return ((s_commandAttributes[commandIndex] & NO_SESSIONS) == 0);
289 }
```

9.3.3.10 IsHandleInResponse()

This function determines if a command has a handle in the response

```
290 BOOL
291 IsHandleInResponse(
292     COMMAND_INDEX    commandIndex
293     )
294 {
295     return ((s_commandAttributes[commandIndex] & R_HANDLE) != 0);
296 }
```

9.3.3.11 IsWriteOperation()

Checks to see if an operation will write to an NV Index and is subject to being blocked by read-lock

```
297 BOOL
298 IsWriteOperation(
299     COMMAND_INDEX    commandIndex   // IN: Command to check
300     )
```

 Copyright © TCG 2006-2020

```
301 {

```
360 #endif
361 }
```

9.3.3.13 CommandCapGetCCList()

This function returns a list of implemented commands and command attributes starting from the command in *commandCode*.

Return Value	Meaning
YES	more command attributes are available
NO	no more command attributes are available

```
362 TPMI_YES_NO
363 CommandCapGetCCList(
364     TPM_CC          commandCode,    // IN: start command code
365     UINT32          count,          // IN: maximum count for number of entries in
366                                     //     'commandList'
367     TPML_CCA       *commandList     // OUT: list of TPMA_CC
368     )
369 {
370     TPMI_YES_NO      more = NO;
371     COMMAND_INDEX    commandIndex;

9.4 Entity.c

9.4.1 Description

The functions in this file are used for accessing properties for handles of various types. Functions in other files require handles of a specific type but the functions in this file allow use of any handle type.

9.4.2 Includes

```
1   #include "Tpm.h"
```

9.4.3 Functions

9.4.3.1 EntityGetLoadStatus()

This function will check that all the handles access loaded entities.

Error Returns	Meaning
TPM_RC_HANDLE	handle type does not match
TPM_RC_REFERENCE_Hx	entity is not present
TPM_RC_HIERARCHY	entity belongs to a disabled hierarchy
TPM_RC_OBJECT_MEMORY	handle is an evict object but there is no space to load it to RAM

```
2   TPM_RC

309     }
310     return hashAlg;
311 }
```

9.4.3.4 EntityGetName()

This function returns the Name associated with a handle.

```
312 TPM2B_NAME *
313 EntityGetName(
314     TPMI_DH_ENTITY   handle,         // IN: handle of entity
315     TPM2B_NAME      *name            // OUT: name of entity
316     )
317 {
318     switch(HandleGetType(handle))
319     {
320         case TPM_HT_TRANSIENT:
321         {
322             // Name for an object
323             OBJECT      *object = HandleToObject(handle);
324             // an object with no nameAlg has no name
325             if(object->publicArea.nameAlg == TPM_ALG_NULL)
326                 name->b.size = 0;
327             else
328                 *name = object->name;
```

```
329                 break;
330             }
331         case TPM_HT_NV_INDEX:
332             // Name for a NV index
333             NvGetNameByIndexHandle(handle, name);
334             break;
335         default:
336             // For all other types, the handle is the Name
337             name->t.size = sizeof(TPM_HANDLE);
338             UINT32_TO_BYTE_ARRAY(handle, name->t.name);
339             break;
340     }
341     return name;
342 }
```

9.4.3.5 EntityGetHierarchy()

This function returns the hierarchy handle associated with an entity.

a) A handle that is a hierarchy handle is associated with itself.

b) An NV index belongs to TPM_RH_PLATFORM if TPMA_NV_PLATFORMCREATE, is SET, otherwise it belongs to TPM_RH_OWNER

c) An object handle belongs to its hierarchy.

```
343 TPMI_RH_HIERARCHY
344 EntityGetHierarchy(
345     TPMI_DH_ENTITY    handle          // IN :handle of entity
346     )
347 {
348     TPMI_RH_HIERARCHY        hierarchy = TPM_RH_NULL;
349
350     switch(HandleGetType(handle))
351     {
352         case TPM_HT_PERMANENT:
353             // hierarchy for a permanent handle
354             switch(handle)
355             {
356                 case TPM_RH_PLATFORM:
357                 case TPM_RH_ENDORSEMENT:
358                 case TPM_RH_NULL:
359                     hierarchy = handle;
360                     break;
361                 // all other permanent handles are associated with the owner
362                 // hierarchy. (should only be TPM_RH_OWNER and TPM_RH_LOCKOUT)
363                 default:
364                     hierarchy = TPM_RH_OWNER;
365                     break;
366             }
367             break;
368         case TPM_HT_NV_INDEX:
369             // hierarchy for NV index
370         {
371             NV_INDEX        *nvIndex = NvGetIndexInfo(handle, NULL);
372             pAssert(nvIndex != NULL);
373
374             // If only the platform can delete the index, then it is
375             // considered to be in the platform hierarchy, otherwise it
376             // is in the owner hierarchy.
377             if(IS_ATTRIBUTE(nvIndex->publicArea.attributes, TPMA_NV,
378                             PLATFORMCREATE))
379                 hierarchy = TPM_RH_PLATFORM;
380             else
381                 hierarchy = TPM_RH_OWNER;
```

408                 break;
409         }
410         // this is unreachable but it provides a return value for the default
411         // case which makes the complier happy
412         return hierarchy;
413     }
```

9.5 Global.c

9.5.1 Description

This file will instance the TPM variables that are not stack allocated. Descriptions of global variables are in Global.h. There macro macro definitions that allows a variable to be instanced or simply defined as an external variable. When global.h is included from this .c file, GLOBAL_C is defined and values are instanced (and possibly initialized), but when global.h is included by any other file, they are simply defined as external values. DO NOT DEFINE GLOBAL_C IN ANY OTHER FILE.

NOTE: This is a change from previous implementations where Global.h just contained the extern declaration and values were instanced in this file. This change keeps the definition and instance in one file making maintenance easier. The instanced data will still be in the global.obj file.

The OIDs.h file works in a way that is similar to the Global.h with the definition of the values in OIDs.h such that they are instanced in global.obj. The macros that are defined in Global.h are used in OIDs.h in the same way as they are in Global.h.

9.5.2 Defines and Includes

```
1   #define GLOBAL_C
2   #include "Tpm.h"
3   #include "OIDs.h"
4   #if CC_CertifyX509
5   #   include "X509.h"
6   #endif // CC_CertifyX509
```

9.6 Handle.c

9.6.1 Description

This file contains the functions that return the type of a handle.

9.6.2 Includes

```
1 #include "Tpm.h"
```

9.6.3 Functions

9.6.3.1 HandleGetType()

This function returns the type of a handle which is the MSO of the handle.

```
2  TPM_HT
3  HandleGetType(
4      TPM_HANDLE       handle         // IN: a handle to be checked
5      )
6  {
7      // return the upper bytes of input data
8      return (TPM_HT)((handle & HR_RANGE_MASK) >> HR_SHIFT);
9  }
```

9.6.3.2 NextPermanentHandle()

This function returns the permanent handle that is equal to the input value or is the next higher value. If there is no handle with the input value and there is no next higher value, it returns 0:

```
10 TPM_HANDLE
11 NextPermanentHandle(
12     TPM_HANDLE       inHandle       // IN: the handle to check
13     )
14 {
15     // If inHandle is below the start of the range of permanent handles
16     // set it to the start and scan from there
17     if(inHandle < TPM_RH_FIRST)
18         inHandle = TPM_RH_FIRST;
19     // scan from input value until we find an implemented permanent handle
20     // or go out of range
21     for(; inHandle <= TPM_RH_LAST; inHandle++)
22     {
23         switch(inHandle)
24         {
25             case TPM_RH_OWNER:
26             case TPM_RH_NULL:
27             case TPM_RS_PW:
28             case TPM_RH_LOCKOUT:
29             case TPM_RH_ENDORSEMENT:
30             case TPM_RH_PLATFORM:
31             case TPM_RH_PLATFORM_NV:
32 #ifdef  VENDOR_PERMANENT
33             case VENDOR_PERMANENT:
34 #endif
35 // Each of the implemented ACT
36 #define ACT_IMPLEMENTED_CASE(N)                                              \
37             case TPM_RH_ACT_##N:
38
```

```
39                  FOR_EACH_ACT(ACT_IMPLEMENTED_CASE)
40
41                      return inHandle;
42                      break;
43                  default:
44                      break;
45              }
46          }
47          // Out of range on the top
48          return 0;
49      }
```

9.6.3.3 PermanentCapGetHandles()

This function returns a list of the permanent handles of PCR, started from *handle*. If *handle* is larger than the largest permanent handle, an empty list will be returned with *more* set to NO.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
50      TPMI_YES_NO
51      PermanentCapGetHandles(
52          TPM_HANDLE        handle,         // IN: start handle
53          UINT32            count,          // IN: count of returned handles
54          TPML_HANDLE      *handleList      // OUT: list of handle
55          )
56      {
57          TPMI_YES_NO      more = NO;
58          UINT32           i;
59
60          pAssert(HandleGetType(handle) == TPM_HT_PERMANENT);
61
62          // Initialize output handle list
63          handleList->count = 0;
64
65          // The maximum count of handles we may return is MAX_CAP_HANDLES
66          if(count > MAX_CAP_HANDLES) count = MAX_CAP_HANDLES;
67
68          // Iterate permanent handle range
69          for(i = NextPermanentHandle(handle);
70              i != 0; i = NextPermanentHandle(i + 1))
71          {
72              if(handleList->count < count)
73              {
74                  // If we have not filled up the return list, add this permanent
75                  // handle to it
76                  handleList->handle[handleList->count] = i;
77                  handleList->count++;
78              }
79              else
80              {
81                  // If the return list is full but we still have permanent handle
82                  // available, report this and stop iterating
83                  more = YES;
84                  break;
85              }
86          }
87          return more;
88      }
```

9.6.3.4 PermanentHandleGetPolicy()

This function returns a list of the permanent handles of PCR, started from *handle*. If *handle* is larger than the largest permanent handle, an empty list will be returned with *more* set to NO.

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
89  TPMI_YES_NO
90  PermanentHandleGetPolicy(
91      TPM_HANDLE            handle,          // IN: start handle
92      UINT32                count,           // IN: max count of returned handles
93      TPML_TAGGED_POLICY   *policyList       // OUT: list of handle
94      )
95  {
96      TPMI_YES_NO      more = NO;
97
98      pAssert(HandleGetType(handle) == TPM_HT_PERMANENT);
99
100     // Initialize output handle list
101     policyList->count = 0;
102
103     // The maximum count of policies we may return is MAX_TAGGED_POLICIES
104     if(count > MAX_TAGGED_POLICIES)
105         count = MAX_TAGGED_POLICIES;
106
107     // Iterate permanent handle range
108     for(handle = NextPermanentHandle(handle);
109         handle != 0;
110         handle = NextPermanentHandle(handle + 1))
111     {
112         TPM2B_DIGEST     policyDigest;
113         TPM_ALG_ID       policyAlg;
114         // Check to see if this permanent handle has a policy
115         policyAlg = EntityGetAuthPolicy(handle, &policyDigest);
116         if(policyAlg == TPM_ALG_ERROR)
117            continue;
118         if(policyList->count < count)
119         {
120             // If we have not filled up the return list, add this
121             // policy to the list;
122             policyList->policies[policyList->count].handle = handle;
123             policyList->policies[policyList->count].policyHash.hashAlg = policyAlg;
124             MemoryCopy(&policyList->policies[policyList->count].policyHash.digest,
125                        policyDigest.t.buffer, policyDigest.t.size);
126             policyList->count++;
127         }
128         else
129         {
130             // If the return list is full but we still have permanent handle
131             // available, report this and stop iterating
132             more = YES;
133             break;
134         }
135     }
136     return more;
137 }
```

9.7 IoBuffers.c

9.7.1 Includes and Data Definitions

This definition allows this module to **see** the values that are private to this module but kept in Global.c for ease of state migration.

```
1  #define IO_BUFFER_C
2  #include "Tpm.h"
3  #include "IoBuffers_fp.h"
```

9.7.2 Buffers and Functions

These buffers are set aside to hold command and response values. In this implementation, it is not guaranteed that the code will stop accessing the *s_actionInputBuffer* before starting to put values in the *s_actionOutputBuffer* so different buffers are required.

9.7.2.1 MemoryIoBufferAllocationReset()

This function is used to reset the allocation of buffers.

```
4  void
5  MemoryIoBufferAllocationReset(
6      void
7  )
8  {
9      s_actionIoAllocation = 0;
10 }
```

9.7.2.2 MemoryIoBufferZero()

Function zeros the action I/O buffer at the end of a command. Calling this is not mandatory for proper functionality.

```
11 void
12 MemoryIoBufferZero(
13     void
14 )
15 {
16     memset(s_actionIoBuffer, 0, s_actionIoAllocation);
17 }
```

9.7.2.3 MemoryGetInBuffer()

This function returns the address of the buffer into which the command parameters will be unmarshaled in preparation for calling the command actions.

```
18 BYTE *
19 MemoryGetInBuffer(
20     UINT32           size           // Size, in bytes, required for the input
21                                     // unmarshaling
22     )
23 {
24     pAssert(size <= sizeof(s_actionIoBuffer));
25     // In this implementation, a static buffer is set aside for the command action
26     // buffers. The buffer is shared between input and output. This is because
27     // there is no need to allocate for the worst case input and worst case output
```

 Copyright © TCG 2006-2020

```
28      // at the same time.
29      // Round size up
30      #define UoM  (sizeof(s_actionIoBuffer[0]))
31      size = (size + (UoM - 1)) & (UINT32_MAX - (UoM - 1));
32      memset(s_actionIoBuffer, 0, size);
33      s_actionIoAllocation = size;
34      return (BYTE *)&s_actionIoBuffer[0];
35  }
```

9.7.2.4 MemoryGetOutBuffer()

This function returns the address of the buffer into which the command action code places its output values.

```
36  BYTE *
37  MemoryGetOutBuffer(
38      UINT32          size            // required size of the buffer
39      )
40  {
41      BYTE        *retVal = (BYTE *)(&s_actionIoBuffer[s_actionIoAllocation / UoM]);
42      pAssert((size + s_actionIoAllocation) < (sizeof(s_actionIoBuffer)));
43      // In this implementation, a static buffer is set aside for the command action
44      // output buffer.
45      memset(retVal, 0, size);
46      s_actionIoAllocation += size;
47      return retVal;
48  }
```

9.7.2.5 IsLabelProperlyFormatted()

This function checks that a label is a null-terminated string.

NOTE: this function is here because there was no better place for it.

Return Value	Meaning
TRUE(1)	string is null terminated
FALSE(0)	string is not null terminated

```
49  BOOL
50  IsLabelProperlyFormatted(
51      TPM2B           *x
52      )
53  {
54      return (((x)->size == 0) || ((x)->buffer[(x)->size - 1] == 0));
55  }
```

9.8 Locality.c

9.8.1 Includes

```
1    #include "Tpm.h"
```

9.8.2 LocalityGetAttributes()

This function will convert a locality expressed as an integer into TPMA_LOCALITY form.

The function returns the locality attribute.

```
2    TPMA_LOCALITY
3    LocalityGetAttributes(
4        UINT8           locality        // IN: locality value
5        )
6    {
7        TPMA_LOCALITY           locality_attributes;
8        BYTE                   *localityAsByte = (BYTE *)&locality_attributes;
9
10       MemorySet(&locality_attributes, 0, sizeof(TPMA_LOCALITY));
11       switch(locality)
12       {
13           case 0:
14               SET_ATTRIBUTE(locality_attributes, TPMA_LOCALITY, TPM_LOC_ZERO);
15               break;
16           case 1:
17               SET_ATTRIBUTE(locality_attributes, TPMA_LOCALITY, TPM_LOC_ONE);
18               break;
19           case 2:
20               SET_ATTRIBUTE(locality_attributes, TPMA_LOCALITY, TPM_LOC_TWO);
21               break;
22           case 3:
23               SET_ATTRIBUTE(locality_attributes, TPMA_LOCALITY, TPM_LOC_THREE);
24               break;
25           case 4:
26               SET_ATTRIBUTE(locality_attributes, TPMA_LOCALITY, TPM_LOC_FOUR);
27               break;
28           default:
29               pAssert(locality > 31);
30               *localityAsByte = locality;
31               break;
32       }
33       return locality_attributes;
34   }
```

9.9 Manufacture.c

9.9.1 Description

This file contains the function that performs the **manufacturing** of the TPM in a simulated environment. These functions should not be used outside of a manufacturing or simulation environment.

9.9.2 Includes and Data Definitions

```
1  #define MANUFACTURE_C
2  #include "Tpm.h"
3  #include "TpmSizeChecks_fp.h"
```

9.9.3 Functions

9.9.3.1 TPM_Manufacture()

This function initializes the TPM values in preparation for the TPM's first use. This function will fail if previously called. The TPM can be re-manufactured by calling TPM_Teardown() first and then calling this function again.

Return Value	Meaning
-1	failure
0	success
1	manufacturing process previously performed

```
4  LIB_EXPORT int
5  TPM_Manufacture(
6      int                firstTime        // IN: indicates if this is the first call from
7                                          //     main()
8      )
9  {
10     TPM_SU             orderlyShutdown;
11
12 #if RUNTIME_SIZE_CHECKS
13     // Call the function to verify the sizes of values that result from different
14     // compile options.
15     if(!TpmSizeChecks())
16         return -1;
17 #endif
18 #if LIBRARY_COMPATIBILITY_CHECK
19 // Make sure that the attached library performs as expected.
20     if(!MathLibraryCompatibilityCheck())
21         return -1;
22 #endif
23
24     // If TPM has been manufactured, return indication.
25     if(!firstTime && g_manufactured)
26         return 1;
27
28     // Do power on initializations of the cryptographic libraries.
29     CryptInit();
30
31     s_DAPendingOnNV = FALSE;
32
33     // initialize NV
34     NvManufacture();
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
35
36      // Clear the magic value in the DRBG state
37      go.drbgState.magic = 0;
38
39      CryptStartup(SU_RESET);
40
41      // default configuration for PCR
42      PCRSimStart();
43
44      // initialize pre-installed hierarchy data
45      // This should happen after NV is initialized because hierarchy data is
46      // stored in NV.
47      HierarchyPreInstall_Init();
48
49      // initialize dictionary attack parameters
50      DAPreInstall_Init();
51
52      // initialize PP list
53      PhysicalPresencePreInstall_Init();
54
55      // initialize command audit list
56      CommandAuditPreInstall_Init();
57
58      // first start up is required to be Startup(CLEAR)
59      orderlyShutdown = TPM_SU_CLEAR;
60      NV_WRITE_PERSISTENT(orderlyState, orderlyShutdown);
61
62      // initialize the firmware version
63      gp.firmwareV1 = FIRMWARE_V1;
64  #ifdef FIRMWARE_V2
65      gp.firmwareV2 = FIRMWARE_V2;
66  #else
67      gp.firmwareV2 = 0;
68  #endif
69      NV_SYNC_PERSISTENT(firmwareV1);
70      NV_SYNC_PERSISTENT(firmwareV2);
71
72      // initialize the total reset counter to 0
73      gp.totalResetCount = 0;
74      NV_SYNC_PERSISTENT(totalResetCount);
75
76      // initialize the clock stuff
77      go.clock = 0;
78      go.clockSafe = YES;
79
80      NvWrite(NV_ORDERLY_DATA, sizeof(ORDERLY_DATA), &go);
81
82      // Commit NV writes.  Manufacture process is an artificial process existing
83      // only in simulator environment and it is not defined in the specification
84      // that what should be the expected behavior if the NV write fails at this
85      // point.  Therefore, it is assumed the NV write here is always success and
86      // no return code of this function is checked.
87      NvCommit();
88
89      g_manufactured = TRUE;
90
91      return 0;
92  }
```

9.9.3.2 TPM_TearDown()

This function prepares the TPM for re-manufacture. It should not be implemented in anything other than a simulated TPM.

In this implementation, all that is needs is to stop the cryptographic units and set a flag to indicate that the TPM can be re-manufactured. This should be all that is necessary to start the manufacturing process again.

Return Value	Meaning
0	success
1	TPM not previously manufactured

```
93   LIB_EXPORT int
94   TPM_TearDown(
95       void
96       )
97   {
98       g_manufactured = FALSE;
99       return 0;
100  }
```

9.9.3.3 TpmEndSimulation()

This function is called at the end of the simulation run. It is used to provoke printing of any statistics that might be needed.

```
101  LIB_EXPORT void
102  TpmEndSimulation(
103      void
104      )
105  {
106  #if SIMULATION
107      HashLibSimulationEnd();
108      SymLibSimulationEnd();
109      MathLibSimulationEnd();
110  #if ALG_RSA
111      RsaSimulationEnd();
112  #endif
113  #if ALG_ECC
114      EccSimulationEnd();
115  #endif
116  #endif // SIMULATION
117  }
```

9.10 Marshal.c

9.10.1 Introduction

This file contains the marshaling and unmarshaling code.

The marshaling and unmarshaling code and function prototypes are not listed, as the code is repetitive, long, and not very useful to read. Examples of a few unmarshaling routines are provided. Most of the others are similar.

Depending on the table header flags, a type will have an unmarshaling routine and a marshaling routine The table header flags that control the generation of the unmarshaling and marshaling code are delimited by angle brackets ("<>") in the table header. If no brackets are present, then both unmarshaling and marshaling code is generated (i.e., generation of both marshaling and unmarshaling code is the default).

9.10.2 Unmarshal and Marshal a Value

In TPM 2.0 Part 2, a TPMI_DI_OBJECT is defined by this table:

Table xxx — Definition of (TPM_HANDLE) TPMI_DH_OBJECT Type

Values	Comments
{TRANSIENT_FIRST:TRANSIENT_LAST}	allowed range for transient objects
{PERSISTENT_FIRST:PERSISTENT_LAST}	allowed range for persistent objects
+TPM_RH_NULL	the null handle
#TPM_RC_VALUE	

This generates the following unmarshaling code:

```
1   TPM_RC
2   TPMI_DH_OBJECT_Unmarshal(TPMI_DH_OBJECT *target, BYTE **buffer, INT32 *size,
3                            BOOL flag)
4   {
5       TPM_RC    result;
6       result = TPM_HANDLE_Unmarshal((TPM_HANDLE *)target, buffer, size);
7       if(result != TPM_RC_SUCCESS)
8           return result;
9       if(*target == TPM_RH_NULL)
10      {
11          if(flag)
12              return TPM_RC_SUCCESS;
13          else
14              return TPM_RC_VALUE;
15      }
16      if(((*target < TRANSIENT_FIRST) || (*target > TRANSIENT_LAST))
17        &&((*target < PERSISTENT_FIRST) || (*target > PERSISTENT_LAST)))
18              return TPM_RC_VALUE;
19      return TPM_RC_SUCCESS;
20  }
```

and the following marshaling code:

NOTE The marshaling code does not do parameter checking, as the TPM is the source of the marshaling data.

```
1   UINT16
2   TPMI_DH_OBJECT_Marshal(TPMI_DH_OBJECT *source, BYTE **buffer, INT32 *size)
```

 Copyright © TCG 2006-2020

```
3   {
4       return UINT32_Marshal((UINT32 *)source, buffer, size);
5   }
```

An additional script is used to do the work that might be done by a linker or globally optimizing compiler. It searches for functions like TPMI_DH_OBJECT_Marshal() that do nothing but call another function and replaces the function with a #define.

```
6   #define TPMI_DH_OBJECT_Marshal(source, buffer, size)      \
7         UINT32_Marshal((UINT32 *)source, buffer, size)
```

When replacing the function with a #define, the #define is placed in marshal_fp.h and the function body is removed from marshal.c.

9.10.3 Unmarshal and Marshal a Union

In TPM 2.0 Part 2, a TPMU_PUBLIC_PARMS union is defined by:

Table xxx — Definition of TPMU_PUBLIC_PARMS Union <IN/OUT, S>

Parameter	Type	Selector	Description
keyedHash	TPMS_KEYEDHASH_PARMS	TPM_ALG_KEYEDHASH	sign | encrypt | neither
symDetail	TPMT_SYM_DEF_OBJECT	TPM_ALG_SYMCIPHER	a symmetric block cipher
rsaDetail	TPMS_RSA_PARMS	TPM_ALG_RSA	decrypt + sign
eccDetail	TPMS_ECC_PARMS	TPM_ALG_ECC	decrypt + sign
asymDetail	TPMS_ASYM_PARMS		common scheme structure for RSA and ECC keys
NOTE The Description column indicates which of TPMA_OBJECT.*decrypt* or TPMA_OBJECT.*sign* may be set. "+" indicates that both may be set but one shall be set. "|" indicates the optional settings.			

From this table, the following unmarshaling code is generated.

```
1   TPM_RC
2   TPMU_PUBLIC_PARMS_Unmarshal(TPMU_PUBLIC_PARMS *target, BYTE **buffer, INT32 *size,
3                               UINT32 selector)
4   {
5       switch(selector) {
6   #if ALG_KEYEDHASH
7           case TPM_ALG_KEYEDHASH:
8               return TPMS_KEYEDHASH_PARMS_Unmarshal(
9                          (TPMS_KEYEDHASH_PARMS *)&(target->keyedHash), buffer, size);
10  #endif
11  #if ALG_SYMCIPHER
12          case TPM_ALG_SYMCIPHER:
13              return TPMT_SYM_DEF_OBJECT_Unmarshal(
14                     (TPMT_SYM_DEF_OBJECT *)&(target->symDetail), buffer, size, FALSE);
15  #endif
16  #if ALG_RSA
17          case TPM_ALG_RSA:
18              return TPMS_RSA_PARMS_Unmarshal(
19                              (TPMS_RSA_PARMS *)&(target->rsaDetail), buffer, size);
20  #endif
21  #if ALG_ECC
22          case TPM_ALG_ECC:
23              return TPMS_ECC_PARMS_Unmarshal(
24                              (TPMS_ECC_PARMS *)&(target->eccDetail), buffer, size);
25  #endif
26      }
```

 Copyright © TCG 2006-2020

```
27      return TPM_RC_SELECTOR;
28  }
```

NOTE The #if/#endif directives are added whenever a value is dependent on an algorithm ID so that removing the algorithm definition will remove the related code.

The marshaling code for the union is:

```
1   UINT16
2   TPMU_PUBLIC_PARMS_Marshal(TPMU_PUBLIC_PARMS *source, BYTE **buffer, INT32 *size,
3                              UINT32 selector)
4   {
5       switch(selector) {
6   #if ALG_KEYEDHASH
7           case TPM_ALG_KEYEDHASH:
8               return TPMS_KEYEDHASH_PARMS_Marshal(
9                             (TPMS_KEYEDHASH_PARMS *)&(source->keyedHash), buffer, size);
10  #endif
11  #if ALG_SYMCIPHER
12          case TPM_ALG_SYMCIPHER:
13              return TPMT_SYM_DEF_OBJECT_Marshal(
14                             (TPMT_SYM_DEF_OBJECT *)&(source->symDetail), buffer, size);
15  #endif
16  #if ALG_RSA
17          case TPM_ALG_RSA:
18              return TPMS_RSA_PARMS_Marshal(
19                              (TPMS_RSA_PARMS *)&(source->rsaDetail), buffer, size);
20  #endif
21  #if ALG_ECC
22          case TPM_ALG_ECC:
23              return TPMS_ECC_PARMS_Marshal(
24                               (TPMS_ECC_PARMS *)&(source->eccDetail), buffer, size);
25  #endif
26      }
27      assert(1);
28      return 0;
29  }
```

For the marshaling and unmarshaling code, a value in the structure containing the union provides the value used for *selector*. The example in the next section illustrates this.

 Copyright © TCG 2006-2020

9.10.4 Unmarshal and Marshal a Structure

In TPM 2.0 Part 2, the TPMT_PUBLIC structure is defined by:

Table xxx — Definition of TPMT_PUBLIC Structure

Parameter	Type	Description
type	TPMI_ALG_PUBLIC	"algorithm" associated with this object
nameAlg	+TPMI_ALG_HASH	algorithm used for computing the Name of the object NOTE The "+" indicates that the instance of a TPMT_PUBLIC may have a "+" to indicate that the nameAlg may be TPM_ALG_NULL.
objectAttributes	TPMA_OBJECT	attributes that, along with *type*, determine the manipulations of this object
authPolicy	TPM2B_DIGEST	optional policy for using this key The policy is computed using the *nameAlg* of the object. NOTE shall be the Empty Buffer if no authorization policy is present
[type]parameters	TPMU_PUBLIC_PARMS	the algorithm or structure details
[type]unique	TPMU_PUBLIC_ID	the unique identifier of the structure For an asymmetric key, this would be the public key.

This structure is tagged (the first value indicates the structure type), and that tag is used to determine how the parameters and unique fields are unmarshaled and marshaled. The use of the type for specifying the union selector is emphasized below.

The unmarshaling code for the structure in the table above is:

```
1  TPM_RC
2  TPMT_PUBLIC_Unmarshal(TPMT_PUBLIC *target, BYTE **buffer, INT32 *size, BOOL flag)
3  {
4      TPM_RC     result;
5      result = TPMI_ALG_PUBLIC_Unmarshal((TPMI_ALG_PUBLIC *)&(target->type),
6                                         buffer, size);
7      if(result != TPM_RC_SUCCESS)
8          return result;
9      result = TPMI_ALG_HASH_Unmarshal((TPMI_ALG_HASH *)&(target->nameAlg),
10                                      buffer, size, flag);
11     if(result != TPM_RC_SUCCESS)
12         return result;
13     result = TPMA_OBJECT_Unmarshal((TPMA_OBJECT *)&(target->objectAttributes),
14                                    buffer, size);
15     if(result != TPM_RC_SUCCESS)
16         return result;
17     result = TPM2B_DIGEST_Unmarshal((TPM2B_DIGEST *)&(target->authPolicy),
18                                     buffer, size);
19     if(result != TPM_RC_SUCCESS)
20         return result;
21
22     result = TPMU_PUBLIC_PARMS_Unmarshal((TPMU_PUBLIC_PARMS *)&(target->parameters),
23                                          buffer, size, (UINT32)target->type);
24     if(result != TPM_RC_SUCCESS)
25         return result;
26
27     result = TPMU_PUBLIC_ID_Unmarshal((TPMU_PUBLIC_ID *)&(target->unique),
28                                       buffer, size, (UINT32)target->type);
29     if(result != TPM_RC_SUCCESS)
30         return result;
31
32     return TPM_RC_SUCCESS;
33 }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

The marshaling code for the TPMT_PUBLIC structure is:

```
1   UINT16
2   TPMT_PUBLIC_Marshal(TPMT_PUBLIC *source, BYTE **buffer, INT32 *size)
3   {
4       UINT16    result = 0;
5       result = (UINT16)(result + TPMI_ALG_PUBLIC_Marshal(
6                                  (TPMI_ALG_PUBLIC *)&(source->type), buffer, size));
7       result = (UINT16)(result + TPMI_ALG_HASH_Marshal(
8                                 (TPMI_ALG_HASH *)&(source->nameAlg), buffer, size))
9   ;
10      result = (UINT16)(result + TPMA_OBJECT_Marshal(
11                            (TPMA_OBJECT *)&(source->objectAttributes), buffer, size));
12
13      result = (UINT16)(result + TPM2B_DIGEST_Marshal(
14                                (TPM2B_DIGEST *)&(source->authPolicy), buffer, size));
15
16      result = (UINT16)(result + TPMU_PUBLIC_PARMS_Marshal(
17                            (TPMU_PUBLIC_PARMS *)&(source->parameters), buffer, size,
18                                                           (UINT32)source->type));
19
20      result = (UINT16)(result + TPMU_PUBLIC_ID_Marshal(
21                                (TPMU_PUBLIC_ID *)&(source->unique), buffer, size,
22                                                           (UINT32)source->type));
23
24      return result;
25  }
```

9.10.5 Unmarshal and Marshal an Array

In TPM 2.0 Part 2, the TPML_DIGEST is defined by:

Table xxx — Definition of TPML_DIGEST Structure

Parameter	Type	Description
count {2:}	UINT32	number of digests in the list, minimum is two
digests[count]{:8}	TPM2B_DIGEST	a list of digests For TPM2_PolicyOR(), all digests will have been computed using the digest of the policy session. For TPM2_PCR_Read(), each digest will be the size of the digest for the bank containing the PCR.
#TPM_RC_SIZE		response code when count is not at least two or is greater than 8

The *digests* parameter is an array of up to *count* structures (TPM2B_DIGESTS). The auto-generated code to Unmarshal this structure is:

```
1   TPM_RC
2   TPML_DIGEST_Unmarshal(TPML_DIGEST *target, BYTE **buffer, INT32 *size)
3   {
4       TPM_RC    result;
5       result = UINT32_Unmarshal((UINT32 *)&(target->count), buffer, size);
6       if(result != TPM_RC_SUCCESS)
7           return result;
8
9       if( (target->count < 2))     // This check is triggered by the {2:} notation
10                                    // on 'count'
11          return TPM_RC_SIZE;
12
13      if((target->count) > 8)      // This check is triggered by the {:8} notation
```

 Copyright © TCG 2006-2020

```
14                                     // on 'digests'.
15          return TPM_RC_SIZE;
16
17      result = TPM2B_DIGEST_Array_Unmarshal((TPM2B_DIGEST *)(target->digests),
18                                             buffer, size, (INT32)(target->count));
19      if(result != TPM_RC_SUCCESS)
20          return result;
21
22      return TPM_RC_SUCCESS;
23  }
```

The routine unmarshals a *count* value and passes that value to a routine that unmarshals an array of TPM2B_DIGEST values. The unmarshaling code for the array is:

```
1   TPM_RC
2   TPM2B_DIGEST_Array_Unmarshal(TPM2B_DIGEST *target, BYTE **buffer, INT32 *size,
3                                INT32 count)
4   {
5       TPM_RC    result;
6       INT32 i;
7       for(i = 0; i < count; i++) {
8           result = TPM2B_DIGEST_Unmarshal(&target[i], buffer, size);
9           if(result != TPM_RC_SUCCESS)
10              return result;
11      }
12      return TPM_RC_SUCCESS;
13  }
14
```

Marshaling of the TPML_DIGEST uses a similar scheme with a structure specifying the number of elements in an array and a subsequent call to a routine to marshal an array of that type.

```
1   UINT16
2   TPML_DIGEST_Marshal(TPML_DIGEST *source, BYTE **buffer, INT32 *size)
3   {
4       UINT16    result = 0;
5       result = (UINT16)(result + UINT32_Marshal((UINT32 *)&(source->count), buffer,
6                                                                              size));
7       result = (UINT16)(result + TPM2B_DIGEST_Array_Marshal(
8                                  (TPM2B_DIGEST *)(source->digests), buffer, size,
9                                  (INT32)(source->count)));
10
11      return result;
12  }
```

The marshaling code for the array is:

```
1   TPM_RC
2   TPM2B_DIGEST_Array_Unmarshal(TPM2B_DIGEST *target, BYTE **buffer, INT32 *size,
3                               INT32 count)
4   {
5       TPM_RC    result;
6       INT32 i;
7       for(i = 0; i < count; i++) {
8           result = TPM2B_DIGEST_Unmarshal(&target[i], buffer, size);
9           if(result != TPM_RC_SUCCESS)
10              return result;
11      }
12      return TPM_RC_SUCCESS;
13  }
```

9.10.6 TPM2B Handling

A TPM2B structure is handled as a special case. The unmarshaling code is similar to what is shown in 9.10.5 but the unmarshaling/marshaling is to a union element. Each TPM2B is a union of two sized buffers, one of which is type specific (the 't' element) and the other is a generic value (the 'b' element). This allows each of the TPM2B structures to have some inheritance property with all other TPM2B. The purpose is to allow functions that have parameters that can be any TPM2B structure while allowing other functions to be specific about the type of the TPM2B that is used. When the generic structure is allowed, the input parameter would use the 'b' element and when the type-specific structure is required, the 't' element is used.

When marshaling a TPM2B where the second member is a BYTE array, the size parameter indicates the size of the array. The second member can also be a structure. In this case, the caller does not prefill the size member. The marshaling code must marshal the structure and then back fill the calculated size.

Table xxx — Definition of TPM2B_EVENT Structure

Parameter	Type	Description
size	UINT16	Size of the operand
buffer [size] {:1024}	BYTE	The operand

```
1   TPM_RC
2   TPM2B_EVENT_Unmarshal(TPM2B_EVENT *target, BYTE **buffer, INT32 *size)
3   {
4       TPM_RC    result;
5       result = UINT16_Unmarshal((UINT16 *)&(target->t.size), buffer, size);
6       if(result != TPM_RC_SUCCESS)
7           return result;
8       // if size equal to 0, the rest of the structure is a zero buffer
9       //  so stop processing
10      if(target->t.size == 0)
11          return TPM_RC_SUCCESS;
12      if((target->t.size) > 1024)     // This check is triggered by the {:1024}
13                                      // notation on 'buffer'
14          return TPM_RC_SIZE;
15      result = BYTE_Array_Unmarshal((BYTE *)(target->t.buffer), buffer, size,
16                                    (INT32)(target->t.size));
17      if(result != TPM_RC_SUCCESS)
18          return result;
19      return TPM_RC_SUCCESS;
20  }
```

using these structure definitions:

```
1   typedef union {
2       struct {
3           UINT16         size;
4           BYTE           buffer[1024];
5       }            t;
6       TPM2B        b;
7   } TPM2B_EVENT;
```

9.10.7 Table Marshal Headers

9.10.7.1 TableMarshal.h

```
1   #ifndef _TABLE_DRIVEN_MARSHAL_H_
2   #define _TABLE_DRIVEN_MARSHAL_H_
```

 Copyright © TCG 2006-2020

These are the basic unmarshaling types. This is in the first byte of each structure descriptor that is passed to Marshal()/Unmarshal() for processing.

```
 3  #define UINT_MTYPE          0
 4  #define VALUES_MTYPE        (UINT_MTYPE + 1)
 5  #define TABLE_MTYPE         (VALUES_MTYPE + 1)
 6  #define MIN_MAX_MTYPE       (TABLE_MTYPE + 1)
 7  #define ATTRIBUTES_MTYPE    (MIN_MAX_MTYPE + 1)
 8  #define STRUCTURE_MTYPE     (ATTRIBUTES_MTYPE + 1)
 9  #define TPM2B_MTYPE         (STRUCTURE_MTYPE + 1)
10  #define TPM2BS_MTYPE        (TPM2B_MTYPE + 1)
11  #define LIST_MTYPE          (TPM2BS_MTYPE + 1) // TPML
12  #define ERROR_MTYPE         (LIST_MTYPE + 1)
13  #define NULL_MTYPE          (ERROR_MTYPE + 1)
14  #define COMPOSITE_MTYPE     (NULL_MTYPE + 1)
```

9.10.7.1.1.1 The Marshal Index

A structure is used to hold the values that guide the marshaling/unmarshaling of each of the types. Each structure has a name and an address. For a structure to define a TPMS_name, the structure is a TPMS_name_MARSHAL_STRUCT and its index is TPMS_name_MARSHAL_INDEX. So, to get the proper structure, use the associated marshal index. The marshal index is passed to Marshal() or Unmarshal() and those functions look up the proper structure.

To handle structures that allow a null value, the upper bit of each marshal index indicates if the null value is allowed. This is the NULL_FLAG. It is defined in TableMarshalIndex.h because it is needed by code outside of the marshaling code. A structure will have a list of marshal indexes to indicate what to unmarshal. When that index appears in a structure/union, the value will contain a flag to indicate that the NULL_FLAG should be SET on the call to Unmarshal() to unmarshal the type. The caller simply takes the entry and passes it to Unmarshal() to indicate that the NULL_FLAG is SET. There is also the opportunity to SET the NULL_FLAG in the called structure if the NULL_FLAG was set in the call to the calling structure. This is indicated by:

```
15  #define NULL_MASK       ~(NULL_FLAG)
```

When looking up the value to marshal, the upper two bits of the marshal index are masked to yield the actual index.

```
16  typedef unsigned int        uint;
```

 Copyright © TCG 2006-2020

9.10.7.1.1.2 Modifier Octet Values

These are in used in anything that is an integer value. Theses would not be in structure modifier bytes (they would be used in values in structures but not the STRUCTURE_MTYPE header.

```
17  #define ONE_BYTES           (0)
18  #define TWO_BYTES           (1)
19  #define FOUR_BYTES          (2)
20  #define EIGHT_BYTES         (3)
21  #define SIZE_MASK           (0x3)
22  #define IS_SIGNED           (1 << 2)     // when the unmarshaled type is a signed value
23  #define SIGNED_MASK         (SIZE_MASK | IS_SIGNED)
```

This may be used for any type except a UINT_MTYPE

```
24  #define TAKES_NULL          (1 << 7)     // when the type takes a null
```

When referencing a structure, this flag indicates if a null is to be propagated to the referenced structure or type.

```
25  #define PROPAGATE_SHIFT     7
26  #define PROPAGATE_NULL      (1 << PROPAGATE_SHIFT)
```

Can be used in min-max or table structures.

```
27  #define HAS_BITS            (1 << 6)     // when bit mask is present
```

In a union, we need to know if this is a union of constant arrays.

```
28  #define IS_ARRAY_UNION      (1 << 6)
```

In a TPM2BS_MTYPE

```
29  #define SIZE_EQUAL          (1 << 6)
```

Right now, there are two spare bits in the modifiers field. Within the descriptor word of each entry in a StructMarsh_mst(), there is a selector field to determine which of the sub-types the entry represents and a field that is used to reference another structure entry. This is a 6-bit field allowing a structure to have 64 entries. This should be more than enough as the structures are not that long. As of now, only 10-bits of the descriptor word leaving room for expansion. These are the values used in a STRUCTURE_MTYPE to identify the sub-type of the thing being processed

```
30  #define SIMPLE_STYPE                0
31  #define UNION_STYPE                 1
32  #define ARRAY_STYPE                 2
```

The code used GET_ to get the element type and the compiler uses SET_ to initialize the value. The element type is the three bits (2:0).

```
33  #define GET_ELEMENT_TYPE(val)       (val & 7)
34  #define SET_ELEMENT_TYPE(val)       (val & 7)
```

When an entry is an array or union, this references the structure entry that contains the dimension or selector value. The code then uses this number to look up the structure entry for that element to find out what it and where is it in memory. When this is not a reference, it is a simple type and it could be used as an array value or a union selector. When a simple value, this field contains the size of the associated value (ONE_BYTES, TWO_BYTES ...) The entry size/number is 6 bits (13:8).

 Copyright © TCG 2006-2020

```
35  #define GET_ELEMENT_NUMBER(val)      (((val) >> 8) & 0x3F)
36  #define SET_ELEMENT_NUMBER(val)      (((val) & 0x3F) << 8)
37  #define GET_ELEMENT_SIZE(val)        GET_ELEMENT_NUMBER(val)
38  #define SET_ELEMENT_SIZE(val)        SET_ELEMENT_NUMBER(val)
```

This determines if the null flag is propagated to this type. If generate, the NULL_FLAG is SET in the index value. This flag is one bit (7)

```
39  #define ELEMENT_PROPAGATE            (1 << PROPAGATE_SHIFT)
40  #define INDEX_MASK                   ((UINT16)NULL_MASK)
```

This is used in all bit-field checks. These are used when a value that is checked is conditional (dependent on the compilation). For example, if AES_128 is (NO), then the bit associated with AES_128 will be 0. In some cases, the bit value is found by checking that the input is within the range of the table, and then using the (val - min) value to index the bit. This would be used when verifying that a particular algorithm is implemented. In other cases, there is a bit for each value in a table. For example, if checking the key sizes, there is a list of possible key sizes allowed by the algorithm registry and a bit field to indicate if that key size is allowed in the implementation. The smallest bit field has 32-bits 32-bits because it is implemented as part of the *values* array of the structures that allow bit fields.

```
41  #define IS_BIT_SET32(bit, bits)                                              \
42                          ((((UINT32 *)bits)[bit >> 5] & (1 << (bit & 0x1F))) != 0)
```

For a COMPOSITE_MTYPE, the qualifiers byte has an element size and count.

```
43  #define SET_ELEMENT_COUNT(count)     ((count & 0x1F) << 3)
44  #define GET_ELEMENT_COUNT(val)       ((val  >> 3) & 0x1F)
45  #endif // _TABLE_DRIVEN_MARSHAL_H_
```

9.10.7.2 TableMarshalData.h

```
1   #ifndef _Table_Marshal_Data_
2   #define _Table_Marshal_Data_
```

The datatype descriptions for each type if needed in addition to the default types.

```
3   typedef const struct TPM_ECC_CURVE_mst {
4       UINT8       marshalType;
5       UINT8       modifiers;
6       UINT8       errorCode;
7       UINT32      values[4];
8   } TPM_ECC_CURVE_mst;
9   typedef const struct TPM_CLOCK_ADJUST_mst {
10      UINT8       marshalType;
11      UINT8       modifiers;

9.10.7.3 TableMarshalDefines.h

```
1    #ifndef _TABLE_MARSHAL_DEFINES_H_
2    #define _TABLE_MARSHAL_DEFINES_H_
3    #define NULL_SHIFT  15
4    #define NULL_FLAG   (1 << NULL_SHIFT)
```

The range macro processes a min, max value and produces a values that is used in the computation to see if something is within a range. The max value is (max-min). This lets the check for something (*val*) within a range become: if((val - min) <= max) // passes if in range if((val - min) > max) // passes if not in range This works because all values are converted to UINT32 values before the compare. For (val - min), all values greater than or equal to val will become positive values with a value equal to *min* being zero. This means that in an unsigned compare against 'max,' any value that is outside the range will appear to be a number greater than max. The benefit of this operation is that this will work even if the input value is a signed number as long as the input is sign extended.

```
5    #define RANGE(_min_, _max_, _base_)                                           \
6        (UINT32)_min_, (UINT32)((_base_)(_max_ - _min_))
```

This macro is like the offsetof macro but, instead of computing the offset of a structure element, it computes the stride between elements that are in a structure array. This is used instead of sizeof() because the sizeof() operator on a structure can return an implementation dependent value.

```
7    #define STRIDE(s)    ((UINT16)(size_t)&(((s *)0)[1]))
8    #define MARSHAL_REF(TYPE)    ((UINT16)(offsetof(MARSHAL_DATA, TYPE)))
```

This macro creates the entry in the array lookup table

```
9    #define ARRAY_MARSHAL_ENTRY(TYPE)                                            \
10           {(marshalIndex_t)TYPE##_MARSHAL_REF, (UINT16)STRIDE(TYPE)}
```

Defines for array lookup

9.10.7.4.1.1 Structure Entries

A structure contains a list of elements to unmarshal. Each of the entries is a UINT16. The structure descriptor is: The *values* array contains indicators for the things to marshal. The *elements* parameter indicates how many different entities are unmarshaled. This number nominally corresponds to the number of rows in the Part 2 table that describes the structure (the number of rows minus the title row and any error code rows). A schematic of a simple structure entry is shown here but the values are not actually in a structure. As shown, the third value is the offset in the structure where the value is placed when unmarshaled, or fetched from when marshaling. This is sufficient when the element type indicated by *index* is always a simple type and never a union or array.This is just shown for illustrative purposes.

```
4   typedef struct simpleStructureEntry_t {
5       UINT16          qualifiers;         // indicates the type of entry (array, union
6                                           // etc.)
7       marshalIndex_t  index;              // the index into the appropriate array of
8                                           //  the descriptor of this type
9       UINT16          offset;             // where this comes from or is placed
10  } simpleStructureEntry_t;

9.11 MathOnByteBuffers.c

9.11.1 Introduction

This file contains implementation of the math functions that are performed with canonical integers in byte buffers. The canonical integer is big-endian bytes.

```
1   #include "Tpm.h"
```

9.11.2 Functions

9.11.2.1 UnsignedCmpB

This function compare two unsigned values. The values are byte-aligned, big-endian numbers (e.g, a hash).

Return Value	Meaning
1	if (a > b)
0	if (a = b)
-1	if (a < b)

```
2   LIB_EXPORT int
3   UnsignedCompareB(
4       UINT32           aSize,         // IN: size of a
5       const BYTE      *a,             // IN: a
6       UINT32           bSize,         // IN: size of b
7       const BYTE      *b              // IN: b
8       )
9   {
10      UINT32              i;
11      if(aSize > bSize)
12          return 1;
13      else if(aSize < bSize)
14          return -1;
15      else
16      {
17          for(i = 0; i < aSize; i++)
18          {
19              if(a[i] != b[i])
20                  return (a[i] > b[i]) ? 1 : -1;
21          }
22      }
23      return 0;
24  }
```

9.11.2.2 SignedCompareB()

Compare two signed integers:

Return Value	Meaning
1	if a > b
0	if a = b
-1	if a < b

```
25  int
26  SignedCompareB(
27      const UINT32     aSize,          // IN: size of a
28      const BYTE      *a,              // IN: a buffer
29      const UINT32     bSize,          // IN: size of b
30      const BYTE      *b               // IN: b buffer
31      )
32  {
33      int       signA, signB;       // sign of a and b
34
35      // For positive or 0, sign_a is 1
36      // for negative, sign_a is 0
37      signA = ((a[0] & 0x80) == 0) ? 1 : 0;
38
39      // For positive or 0, sign_b is 1
40      // for negative, sign_b is 0
41      signB = ((b[0] & 0x80) == 0) ? 1 : 0;
42
43      if(signA != signB)
44      {
45          return signA - signB;
46      }
47      if(signA == 1)
48          // do unsigned compare function
49          return UnsignedCompareB(aSize, a, bSize, b);
50      else
51          // do unsigned compare the other way
52          return 0 - UnsignedCompareB(aSize, a, bSize, b);
53  }
```

9.11.2.3 ModExpB

This function is used to do modular exponentiation in support of RSA. The most typical uses are: *c* = *m*^*e* mod *n* (RSA encrypt) and *m* = *c*^*d* mod *n* (RSA decrypt). When doing decryption, the *e* parameter of the function will contain the private exponent *d* instead of the public exponent *e*.

If the results will not fit in the provided buffer, an error is returned (CRYPT_ERROR_UNDERFLOW). If the results is smaller than the buffer, the results is de-normalized.

This version is intended for use with RSA and requires that *m* be less than *n*.

Error Returns	Meaning
TPM_RC_SIZE	number to exponentiate is larger than the modulus
TPM_RC_NO_RESULT	result will not fit into the provided buffer

```
54  TPM_RC
55  ModExpB(
56      UINT32           cSize,          // IN: the size of the output buffer. It will
57                                       //     need to be the same size as the modulus
58      BYTE            *c,              // OUT: the buffer to receive the results
59                                       //     (c->size must be set to the maximum size
60                                       //     for the returned value)
61      const UINT32     mSize,
62      const BYTE      *m,              // IN: number to exponentiate
```

 Copyright © TCG 2006-2020

```
63      const UINT32     eSize,
64      const BYTE      *e,              // IN: power
65      const UINT32     nSize,
66      const BYTE      *n               // IN: modulus
67      )
68  {
69      BN_MAX(bnC);
70      BN_MAX(bnM);
71      BN_MAX(bnE);
72      BN_MAX(bnN);
73      NUMBYTES         tSize = (NUMBYTES)nSize;
74      TPM_RC           retVal = TPM_RC_SUCCESS;
75
76      // Convert input parameters
77      BnFromBytes(bnM, m, (NUMBYTES)mSize);
78      BnFromBytes(bnE, e, (NUMBYTES)eSize);
79      BnFromBytes(bnN, n, (NUMBYTES)nSize);
80
81      // Make sure that the output is big enough to hold the result
82      // and that 'm' is less than 'n' (the modulus)
83      if(cSize < nSize)
84          ERROR_RETURN(TPM_RC_NO_RESULT);
85      if(BnUnsignedCmp(bnM, bnN) >= 0)
86          ERROR_RETURN(TPM_RC_SIZE);

88      BnToBytes(bnC, c, &tSize);
89  Exit:
90      return retVal;
91  }
```

9.11.2.4 DivideB()

Divide an integer (*n*) by an integer (*d*) producing a quotient (*q*) and a remainder (*r*). If *q* or *r* is not needed, then the pointer to them may be set to NULL.

Error Returns	Meaning
TPM_RC_NO_RESULT	*q* or *r* is too small to receive the result

```
92  LIB_EXPORT TPM_RC
93  DivideB(
94      const TPM2B     *n,              // IN: numerator
95      const TPM2B     *d,              // IN: denominator
96      TPM2B           *q,              // OUT: quotient
97      TPM2B           *r               // OUT: remainder
98      )
99  {
100     BN_MAX_INITIALIZED(bnN, n);
101     BN_MAX_INITIALIZED(bnD, d);
102     BN_MAX(bnQ);
103     BN_MAX(bnR);
104 //
105     // Do divide with converted values
106     BnDiv(bnQ, bnR, bnN, bnD);
107
108     // Convert the BIGNUM result back to 2B format using the size of the original
109     // number
110     if(q != NULL)
111         if(!BnTo2B(bnQ, q, q->size))
112             return TPM_RC_NO_RESULT;
113     if(r != NULL)
114         if(!BnTo2B(bnR, r, r->size))
115             return TPM_RC_NO_RESULT;
116     return TPM_RC_SUCCESS;
```

```
117     }
```

9.11.2.5 AdjustNumberB()

Remove/add leading zeros from a number in a TPM2B. Will try to make the number by adding or removing leading zeros. If the number is larger than the requested size, it will make the number as small as possible. Setting *requestedSize* to zero is equivalent to requesting that the number be normalized.

```
118     UINT16
119     AdjustNumberB(
120         TPM2B            *num,
121         UINT16            requestedSize
122         )
123     {
124         BYTE             *from;
125         UINT16            i;
126         // See if number is already the requested size
127         if(num->size == requestedSize)
128             return requestedSize;
129         from = num->buffer;
130         if (num->size > requestedSize)
131         {
132         // This is a request to shift the number to the left (remove leading zeros)
133             // Find the first non-zero byte. Don't look past the point where removing
134             // more zeros would make the number smaller than requested, and don't throw
135             // away any significant digits.
136             for(i = num->size; *from == 0 && i > requestedSize; from++, i--);
137             if(i < num->size)
138             {
139                 num->size = i;
140                 MemoryCopy(num->buffer, from, i);
141             }
142         }
143         // This is a request to shift the number to the right (add leading zeros)
144         else
145         {
146             MemoryCopy(&num->buffer[requestedSize - num->size], num->buffer, num->size);
147             MemorySet(num->buffer, 0, requestedSize- num->size);
148             num->size = requestedSize;
149         }
150         return num->size;
151     }
```

9.11.2.6 ShiftLeft()

This function shifts a byte buffer (a TPM2B) one byte to the left. That is, the most significant bit of the most significant byte is lost.

```
152     TPM2B *
153     ShiftLeft(
154         TPM2B        *value          // IN/OUT: value to shift and shifted value out
155     )
156     {
157         UINT16        count = value->size;
158         BYTE         *buffer = value->buffer;
159         if(count > 0)
160         {
161             for(count -= 1; count > 0; buffer++, count--)
162             {
163                 buffer[0] = (buffer[0] << 1) + ((buffer[1] & 0x80) ? 1 : 0);
164             }
165             *buffer <<= 1;
```

```
166     }
167     return value;
168 }
```

9.12 Memory.c

9.12.1 Description

This file contains a set of miscellaneous memory manipulation routines. Many of the functions have the same semantics as functions defined in string.h. Those functions are not used directly in the TPM because they are not *safe*

This version uses string.h after adding guards. This is because the math libraries invariably use those functions so it is not practical to prevent those library functions from being pulled into the build.

9.12.2 Includes and Data Definitions

```
1   #include "Tpm.h"
2   #include "Memory_fp.h"
```

9.12.3 Functions

9.12.3.1 MemoryCopy()

This is an alias for memmove. This is used in place of memcpy because some of the moves may overlap and rather than try to make sure that memmove is used when necessary, it is always used.

```
3   void
4   MemoryCopy(
5       void          *dest,
6       const void    *src,
7       int            sSize
8       )
9   {
10      if(dest != src)
11          memmove(dest, src, sSize);
12  }
```

9.12.3.2 MemoryEqual()

This function indicates if two buffers have the same values in the indicated number of bytes.

Return Value	Meaning
TRUE(1)	all octets are the same
FALSE(0)	all octets are not the same

```
13  BOOL
14  MemoryEqual(
15      const void      *buffer1,       // IN: compare buffer1
16      const void      *buffer2,       // IN: compare buffer2
17      unsigned int     size           // IN: size of bytes being compared
18      )
19  {
20      BYTE          equal = 0;
21      const BYTE   *b1 = (BYTE *)buffer1;
22      const BYTE   *b2 = (BYTE *)buffer2;
23  //
24      // Compare all bytes so that there is no leakage of information
25      // due to timing differences.
26      for(; size > 0; size--)
```

```
27          equal |= (*b1++ ^ *b2++);
28      return (equal == 0);
29  }
```

9.12.3.3 MemoryCopy2B()

This function copies a TPM2B. This can be used when the TPM2B types are the same or different.

This function returns the number of octets in the data buffer of the TPM2B.

```
30  LIB_EXPORT INT16
31  MemoryCopy2B(
32      TPM2B           *dest,          // OUT: receiving TPM2B
33      const TPM2B     *source,        // IN: source TPM2B
34      unsigned int     dSize          // IN: size of the receiving buffer
35      )
36  {
37      pAssert(dest != NULL);
38      if(source == NULL)
39          dest->size = 0;
40      else
41      {
42          pAssert(source->size <= dSize);
43          MemoryCopy(dest->buffer, source->buffer, source->size);
44          dest->size = source->size;
45      }
46      return dest->size;
47  }
```

9.12.3.4 MemoryConcat2B()

This function will concatenate the buffer contents of a TPM2B to an the buffer contents of another TPM2B and adjust the size accordingly (*a* := (*a* | *b*)).

```
48  void
49  MemoryConcat2B(
50      TPM2B           *aInOut,        // IN/OUT: destination 2B
51      TPM2B           *bIn,           // IN: second 2B
52      unsigned int     aMaxSize       // IN: The size of aInOut.buffer (max values for
53                                      //     aInOut.size)
54      )
55  {
56      pAssert(bIn->size <= aMaxSize - aInOut->size);
57      MemoryCopy(&aInOut->buffer[aInOut->size], &bIn->buffer, bIn->size);
58      aInOut->size = aInOut->size + bIn->size;
59      return;
60  }
```

9.12.3.5 MemoryEqual2B()

This function will compare two TPM2B structures. To be equal, they need to be the same size and the buffer contexts need to be the same in all octets.

Return Value	Meaning
TRUE(1)	size and buffer contents are the same
FALSE(0)	size or buffer contents are not the same

```
61  BOOL
62  MemoryEqual2B(
```

```
63      const TPM2B     *aIn,           // IN: compare value
64      const TPM2B     *bIn            // IN: compare value
65      )
66  {
67      if(aIn->size != bIn->size)
68          return FALSE;
69      return MemoryEqual(aIn->buffer, bIn->buffer, aIn->size);
70  }
```

9.12.3.6 MemorySet()

This function will set all the octets in the specified memory range to the specified octet value.

NOTE: A previous version had an additional parameter (*dSize*) that was intended to make sure that the destination would not be overrun. The problem is that, in use, all that was happening was that the value of size was used for *dSize* so there was no benefit in the extra parameter.

```
71  void
72  MemorySet(
73      void            *dest,
74      int              value,
75      size_t           size
76      )
77  {
78      memset(dest, value, size);
79  }
```

9.12.3.7 MemoryPad2B()

Function to pad a TPM2B with zeros and adjust the size.

```
80  void
81  MemoryPad2B(
82      TPM2B           *b,
83      UINT16           newSize
84      )
85  {
86      MemorySet(&b->buffer[b->size], 0, newSize - b->size);
87      b->size = newSize;
88  }
```

9.12.3.8 Uint16ToByteArray()

Function to write an integer to a byte array

```
89  void
90  Uint16ToByteArray(
91      UINT16              i,
92      BYTE                *a
93      )
94  {
95      a[1] = (BYTE)(i); i >>= 8;
96      a[0] = (BYTE)(i);
97  }
```

9.12.3.9 Uint32ToByteArray()

Function to write an integer to a byte array

```
98  void
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
 99     Uint32ToByteArray(
100         UINT32              i,
101         BYTE                *a
102         )
103     {
104         a[3] = (BYTE)(i); i >>= 8;
105         a[2] = (BYTE)(i); i >>= 8;
106         a[1] = (BYTE)(i); i >>= 8;
107         a[0] = (BYTE)(i);
108     }
```

9.12.3.10 Uint64ToByteArray()

Function to write an integer to a byte array

```
109     void
110     Uint64ToByteArray(
111         UINT64               i,
112         BYTE                *a
113         )
114     {
115         a[7] = (BYTE)(i); i >>= 8;
116         a[6] = (BYTE)(i); i >>= 8;
117         a[5] = (BYTE)(i); i >>= 8;
118         a[4] = (BYTE)(i); i >>= 8;
119         a[3] = (BYTE)(i); i >>= 8;
120         a[2] = (BYTE)(i); i >>= 8;
121         a[1] = (BYTE)(i); i >>= 8;
122         a[0] = (BYTE)(i);
123     }
```

9.12.3.11 ByteArrayToUint8()

Function to write a UINT8 to a byte array. This is included for completeness and to allow certain macro expansions

```
124     UINT8
125     ByteArrayToUint8(
126         BYTE                *a
127     )
128     {
129         return          *a;
130     }
```

9.12.3.12 ByteArrayToUint16()

Function to write an integer to a byte array

```
131     UINT16
132     ByteArrayToUint16(
133         BYTE                *a
134     )
135     {
136         return ((UINT16)a[0] << 8) + a[1];
137     }
```

9.12.3.13 ByteArrayToUint32()

Function to write an integer to a byte array

```
138 UINT32
139 ByteArrayToUint32(
140     BYTE                 *a
141 )
142 {
143     return (UINT32)((((((UINT32)a[0] << 8) + a[1]) << 8) + (UINT32)a[2]) << 8) + a[3];
144 }
```

9.12.3.14 ByteArrayToUint64()

Function to write an integer to a byte array

```
145 UINT64
146 ByteArrayToUint64(
147     BYTE                 *a
148     )
149 {
150     return (((UINT64)BYTE_ARRAY_TO_UINT32(a)) << 32) + BYTE_ARRAY_TO_UINT32(&a[4]);
151 }
```

9.13 Power.c

9.13.1 Description

This file contains functions that receive the simulated power state transitions of the TPM.

9.13.2 Includes and Data Definitions

```
1   #define POWER_C
2   #include "Tpm.h"
```

9.13.3 Functions

9.13.3.1 TPMInit()

This function is used to process a power on event.

```
3   void
4   TPMInit(
5       void
6       )
7   {
8       // Set state as not initialized. This means that Startup is required
9       g_initialized = FALSE;
10      return;
11  }
```

9.13.3.2 TPMRegisterStartup()

This function registers the fact that the TPM has been initialized (a TPM2_Startup() has completed successfully).

```
12  BOOL
13  TPMRegisterStartup(
14      void
15      )
16  {
17      g_initialized = TRUE;
18      return TRUE;
19  }
```

9.13.3.3 TPMIsStarted()

Indicates if the TPM has been initialized (a TPM2_Startup() has completed successfully after a _TPM_Init()).

Return Value	Meaning
TRUE(1)	TPM has been initialized
FALSE(0)	TPM has not been initialized

```
20  BOOL
21  TPMIsStarted(
22      void
23      )
24  {
```

 Copyright © TCG 2006-2020

```
25      return g_initialized;
26  }
```

9.14 PropertyCap.c

9.14.1 Description

This file contains the functions that are used for accessing the TPM_CAP_TPM_PROPERTY values.

9.14.2 Includes

```
1    #include "Tpm.h"
```

9.14.3 Functions

9.14.3.1 TPMPropertyIsDefined()

This function accepts a property selection and, if so, sets *value* to the value of the property.

All the fixed values are vendor dependent or determined by a platform-specific specification. The values in the table below are examples and should be changed by the vendor.

Return Value	Meaning
TRUE(1)	referenced property exists and *value* set
FALSE(0)	referenced property does not exist

```
2    static BOOL
3    TPMPropertyIsDefined(
4        TPM_PT              property,       // IN: property
5        UINT32             *value           // OUT: property value
6        )

```

9.14.3.2 TPMCapGetProperties()

This function is used to get the TPM_PT values. The search of properties will start at *property* and continue until *propertyList* has as many values as will fit, or the last property has been reported, or the list has as many values as requested in *count*.

Return Value	Meaning
YES	more properties are available
NO	no more properties to be reported

```
479 TPMI_YES_NO
480 TPMCapGetProperties(
481     TPM_PT                     property,      // IN: the starting TPM property

9.15 Response.c

9.15.1 Description

This file contains the common code for building a response header, including setting the size of the structure. *command* may be NULL if result is not TPM_RC_SUCCESS.

9.15.2 Includes and Defines

```
1   #include "Tpm.h"
```

9.15.3 BuildResponseHeader()

Adds the response header to the response. It will update command->*parameterSize* to indicate the total size of the response.

```
2   void
3   BuildResponseHeader(
4       COMMAND          *command,       // IN: main control structure
5       BYTE             *buffer,        // OUT: the output buffer
6       TPM_RC            result         // IN: the response code
7       )
8   {
9       TPM_ST              tag;
10      UINT32              size;
11
12      if(result != TPM_RC_SUCCESS)
13      {
14          tag = TPM_ST_NO_SESSIONS;
15          size = 10;
16      }
17      else
18      {
19          tag = command->tag;
20          // Compute the overall size of the response
21          size = STD_RESPONSE_HEADER + command->handleNum * sizeof(TPM_HANDLE);
22          size += command->parameterSize;
23          size += (command->tag == TPM_ST_SESSIONS) ?
24              command->authSize + sizeof(UINT32) : 0;
25      }
26      TPM_ST_Marshal(&tag, &buffer, NULL);
27      UINT32_Marshal(&size, &buffer, NULL);
28      TPM_RC_Marshal(&result, &buffer, NULL);
29      if(result == TPM_RC_SUCCESS)
30      {
31          if(command->handleNum > 0)
32              TPM_HANDLE_Marshal(&command->handles[0], &buffer, NULL);
33          if(tag == TPM_ST_SESSIONS)
34              UINT32_Marshal((UINT32 *)&command->parameterSize, &buffer, NULL);
35      }
36      command->parameterSize = size;
37  }
```

9.16 ResponseCodeProcessing.c

9.16.1 Description

This file contains the miscellaneous functions for processing response codes.

NOTE: Currently, there is only one.

9.16.2 Includes and Defines

```
1   #include "Tpm.h"
```

9.16.3 RcSafeAddToResult()

Adds a modifier to a response code as long as the response code allows a modifier and no modifier has already been added.

```
2   TPM_RC
3   RcSafeAddToResult(
4       TPM_RC          responseCode,
5       TPM_RC          modifier
6       )
7   {
8       if((responseCode & RC_FMT1) && !(responseCode & 0xf40))
9          return responseCode + modifier;
10      else
11          return responseCode;
12  }
```

 Copyright © TCG 2006-2020

9.17 TpmFail.c

9.17.1 Includes, Defines, and Types

```
1   #define      TPM_FAIL_C
2   #include     "Tpm.h"
3   #include     <assert.h>
```

On MS C compiler, can save the alignment state and set the alignment to 1 for the duration of the TpmTypes.h include. This will avoid a lot of alignment warnings from the compiler for the unaligned structures. The alignment of the structures is not important as this function does not use any of the structures in TpmTypes.h and only include it for the #defines of the capabilities, properties, and command code values.

```
4   #include "TpmTypes.h"
```

9.17.2 Typedefs

These defines are used primarily for sizing of the local response buffer.

```
5   typedef struct
6   {
7       TPM_ST          tag;
8       UINT32          size;
9       TPM_RC          code;
10  } HEADER;
11  typedef struct
12  {
13      BYTE            tag[sizeof(TPM_ST)];
14      BYTE            size[sizeof(UINT32)];
15      BYTE            code[sizeof(TPM_RC)];
16  } PACKED_HEADER;
17  typedef struct

47      BYTE          cap[sizeof(CAPABILITY_RESPONSE)];
48  } RESPONSES;
```

Buffer to hold the responses. This may be a little larger than required due to padding that a compiler might add.

NOTE: This is not in Global.c because of the specialized data definitions above. Since the data contained in this structure is not relevant outside of the execution of a single command (when the TPM is in failure mode. There is no compelling reason to move all the typedefs to Global.h and this structure to Global.c.

```
49  #ifndef __IGNORE_STATE__ // Don't define this value
50  static BYTE response[sizeof(RESPONSES)];
51  #endif
```

9.17.3 Local Functions

9.17.3.1 MarshalUint16()

Function to marshal a 16 bit value to the output buffer.

```
52  static INT32
53  MarshalUint16(
54      UINT16          integer,
55      BYTE            **buffer
56      )
57  {
58      UINT16_TO_BYTE_ARRAY(integer, *buffer);
59      *buffer += 2;
60      return 2;
61  }
```

9.17.3.2 MarshalUint32()

Function to marshal a 32 bit value to the output buffer.

```
62  static INT32
63  MarshalUint32(
64      UINT32           integer,
65      BYTE            **buffer
66      )
67  {
68      UINT32_TO_BYTE_ARRAY(integer, *buffer);
69      *buffer += 4;
70      return 4;
71  }
```

9.17.3.3 Unmarshal32()

```
72  static BOOL Unmarshal32(
73      UINT32          *target,
74      BYTE            **buffer,
75      INT32           *size
76      )
77  {
78      if((*size -= 4) < 0)
79          return FALSE;
80      *target = BYTE_ARRAY_TO_UINT32(*buffer);
81      *buffer += 4;
82      return TRUE;
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
83  }
```

9.17.3.4 Unmarshal16()

```
84  static BOOL Unmarshal16(
85      UINT16          *target,
86      BYTE           **buffer,
87      INT32           *size
88  )
89  {
90      if((*size -= 2) < 0)
91          return FALSE;
92      *target = BYTE_ARRAY_TO_UINT16(*buffer);
93      *buffer += 2;
94      return TRUE;
95  }
```

9.17.4 Public Functions

9.17.4.1 SetForceFailureMode()

This function is called by the simulator to enable failure mode testing.

```
96  #if SIMULATION
97  LIB_EXPORT void
98  SetForceFailureMode(
99      void
100     )
101 {
102     g_forceFailureMode = TRUE;
103     return;
104 }
105 #endif
```

9.17.4.2 TpmLogFailure()

This function saves the failure values when the code will continue to operate. It if similar to TpmFail() but returns to the caller. The assumption is that the caller will propagate a failure back up the stack.

```
106 void
107 TpmLogFailure(
108 #if FAIL_TRACE
109     const char      *function,
110     int              line,
111 #endif
112     int              code
113 )
114 {
115     // Save the values that indicate where the error occurred.
116     // On a 64-bit machine, this may truncate the address of the string
117     // of the function name where the error occurred.
118 #if FAIL_TRACE
119     s_failFunction = (UINT32)(ptrdiff_t)function;
120     s_failLine = line;
121 #else
122     s_failFunction = 0;
123     s_failLine = 0;
124 #endif
125     s_failCode = code;
126
127     // We are in failure mode
```

```
128     g_inFailureMode = TRUE;
129
130     return;
131 }
```

9.17.4.3 TpmFail()

This function is called by TPM.lib when a failure occurs. It will set up the failure values to be returned on TPM2_GetTestResult().

```
132 NORETURN void
133 TpmFail(
134 #if FAIL_TRACE
135     const char       *function,
136     int               line,
137 #endif
138     int               code
139     )
140 {
141     // Save the values that indicate where the error occurred.
142     // On a 64-bit machine, this may truncate the address of the string
143     // of the function name where the error occurred.
144 #if FAIL_TRACE
145     s_failFunction = (UINT32)(ptrdiff_t)function;
146     s_failLine = line;
147 #else
148     s_failFunction = (UINT32)(ptrdiff_t)NULL;
149     s_failLine = 0;
150 #endif
151     s_failCode = code;
152
153     // We are in failure mode
154     g_inFailureMode = TRUE;
155
156     // if asserts are enabled, then do an assert unless the failure mode code
157     // is being tested.
158 #if SIMULATION
159 #   ifndef NDEBUG
160     assert(g_forceFailureMode);
161 #   endif
162     // Clear this flag
163     g_forceFailureMode = FALSE;
164 #endif
165     // Jump to the failure mode code.
166     // Note: only get here if asserts are off or if we are testing failure mode
167     _plat__Fail();
168 }
```

9.17.4.4 TpmFailureMode

This function is called by the interface code when the platform is in failure mode.

```
169 void
170 TpmFailureMode(
171     unsigned int      inRequestSize,     // IN: command buffer size
172     unsigned char    *inRequest,         // IN: command buffer
173     unsigned int     *outResponseSize,   // OUT: response buffer size
174     unsigned char   **outResponse        // OUT: response buffer
175     )
176 {
177     UINT32            marshalSize;
178     UINT32            capability;
179     HEADER            header;    // unmarshaled command header
```

341     FailureModeReturn:
342         buffer = response;
343         marshalSize = MarshalUint16(TPM_ST_NO_SESSIONS, &buffer);
344         marshalSize += MarshalUint32(10, &buffer);
345         marshalSize += MarshalUint32(TPM_RC_FAILURE, &buffer);
346         *outResponseSize = marshalSize;
347         *outResponse = (unsigned char *)response;
348         return;
349     }
```

9.17.4.5 UnmarshalFail()

This is a stub that is used to catch an attempt to unmarshal an entry that is not defined. Don't ever expect this to be called but...

```
350     void
351     UnmarshalFail(
352         void                *type,
353         BYTE                **buffer,
354         INT32               *size
355         )
356     {
357         NOT_REFERENCED(type);
358         NOT_REFERENCED(buffer);
359         NOT_REFERENCED(size);
360         FAIL(FATAL_ERROR_INTERNAL);
361     }
```

10 Cryptographic Functions

10.1 Headers

10.1.1 BnValues.h

10.1.1.1 Introduction

This file contains the definitions needed for defining the internal BIGNUM structure. A BIGNUM is a pointer to a structure. The structure has three fields. The last field is and array (d) of crypt_uword_t. Each word is in machine format (big- or little-endian) with the words in ascending significance (i.e. words in little-endian order). This is the order that seems to be used in every big number library in the worlds, so...

The first field in the structure (allocated) is the number of words in *d*. This is the upper limit on the size of the number that can be held in the structure. This differs from libraries like OpenSSL as this is not intended to deal with numbers of arbitrary size; just numbers that are needed to deal with the algorithms that are defined in the TPM implementation.

The second field in the structure (size) is the number of significant words in *n*. When this number is zero, the number is zero. The word at used-1 should never be zero. All words between d[size] and d[allocated-1] should be zero.

10.1.1.2 Defines

```
1   #ifndef _BN_NUMBERS_H
2   #define _BN_NUMBERS_H
3   #if RADIX_BITS == 64
4   # define RADIX_LOG2         6
5   #elif RADIX_BITS == 32
6   #define RADIX_LOG2          5
7   #else
8   # error "Unsupported radix"
9   #endif
10  #define RADIX_MOD(x)        ((x) & ((1 << RADIX_LOG2) - 1))
11  #define RADIX_DIV(x)        ((x) >> RADIX_LOG2)
12  #define RADIX_MASK  ((((crypt_uword_t)1) << RADIX_LOG2) - 1)
13  #define BITS_TO_CRYPT_WORDS(bits)       RADIX_DIV((bits) + (RADIX_BITS - 1))
14  #define BYTES_TO_CRYPT_WORDS(bytes)     BITS_TO_CRYPT_WORDS(bytes * 8)

35  #define LARGEST_NUMBER_BITS (LARGEST_NUMBER * 8)
36  #define MAX_ECC_PARAMETER_BYTES (MAX_ECC_KEY_BYTES * ALG_ECC)
```

 Copyright © TCG 2006-2020

These are the basic big number formats. This is convertible to the library- specific format without to much difficulty. For the math performed using these numbers, the value is always positive.

```
37  #define BN_STRUCT_DEF(count) struct {          \
38      crypt_uword_t       allocated;             \
39      crypt_uword_t       size;                  \
40      crypt_uword_t       d[count];              \
41      }
42  typedef BN_STRUCT_DEF(1) bignum_t;
43  #ifndef bigNum
44  typedef bignum_t       *bigNum;
45  typedef const bignum_t *bigConst;
46  #endif
47  extern const bignum_t   BnConstZero;
48
49  // The Functions to access the properties of a big number.
50  // Get number of allocated words
51  #define BnGetAllocated(x)    (unsigned)((x)->allocated)
```

Get number of words used

```
52  #define BnGetSize(x)         ((x)->size)
```

Get a pointer to the data array

```
53  #define BnGetArray(x)        ((crypt_uword_t *)&((x)->d[0]))
```

Get the nth word of a BIGNUM (zero-based)

```
54  #define BnGetWord(x, i)      (crypt_uword_t)((x)->d[i])
```

Some things that are done often. Test to see if a bignum_t is equal to zero

```
55  #define BnEqualZero(bn)    (BnGetSize(bn) == 0)
```

Test to see if a bignum_t is equal to a word type

```
56  #define BnEqualWord(bn, word)                                                  \
57              ((BnGetSize(bn) == 1) && (BnGetWord(bn, 0) == (crypt_uword_t)word))
```

Determine if a BIGNUM is even. A zero is even. Although the indication that a number is zero is that it's size is zero, all words of the number are 0 so this test works on zero.

```
58  #define BnIsEven(n)      ((BnGetWord(n, 0) & 1) == 0)
```

The macros below are used to define BIGNUM values of the required size. The values are allocated on the stack so they can be treated like simple local values. This will call the initialization function for a defined bignum_t. This sets the allocated and used fields and clears the words of *n*.

```
59  #define BN_INIT(name)                                                          \
60      (bigNum)BnInit((bigNum)&(name),                                            \
61                  BYTES_TO_CRYPT_WORDS(sizeof(name.d)))
```

In some cases, a function will need the address of the structure associated with a variable. The structure for a BIGNUM variable of *name* is *name_*. Generally, when the structure is created, it is initialized and a parameter is created with a pointer to the structure. The pointer has the *name* and the structure it points to is *name_*

```
62  #define BN_ADDRESS(name)  (bigNum)&name##_
63  #define BN_STRUCT_ALLOCATION(bits)  (BITS_TO_CRYPT_WORDS(bits) + 1)
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

Create a structure of the correct size.

```
64  #define BN_STRUCT(bits)                                                  \
65      BN_STRUCT_DEF(BN_STRUCT_ALLOCATION(bits))
```

Define a BIGNUM type with a specific allocation

```
66  #define BN_TYPE(name, bits)                                              \
67      typedef BN_STRUCT(bits) bn_##name##_t
```

This creates a local BIGNUM variable of a specific size and initializes it from a TPM2B input parameter.

```
68  #define BN_INITIALIZED(name, bits, initializer)                          \
69      BN_STRUCT(bits)   name##_;                                           \
70      bigNum            name = BnFrom2B(BN_INIT(name##_),                  \
71                                   (const TPM2B *)initializer)
```

Create a local variable that can hold a number with *bits*

```
72  #define BN_VAR(name, bits)                                               \
73      BN_STRUCT(bits)   _##name;                                           \
74      bigNum            name = BN_INIT(_##name)
```

Create a type that can hold the largest number defined by the implementation.

```
75  #define BN_MAX(name)    BN_VAR(name, LARGEST_NUMBER_BITS)
76  #define BN_MAX_INITIALIZED(name, initializer)                            \
77      BN_INITIALIZED(name, LARGEST_NUMBER_BITS, initializer)
```

A word size value is useful

```
78  #define BN_WORD(name)       BN_VAR(name, RADIX_BITS)
```

This is used to created a word-size BIGNUM and initialize it with an input parameter to a function.

```
79  #define BN_WORD_INITIALIZED(name, initial)                               \
80      BN_STRUCT(RADIX_BITS)   name##_;                                     \
81      bigNum                  name = BnInitializeWord((bigNum)&name##_,    \
82                                   BN_STRUCT_ALLOCATION(RADIX_BITS), initial)
```

ECC-Specific Values This is the format for a point. It is always in affine format. The Z value is carried as part of the point, primarily to simplify the interface to the support library. Rather than have the interface layer have to create space for the point each time it is used... The x, y, and z values are pointers to *bigNum* values and not in-line versions of the numbers. This is a relic of the days when there was no standard TPM format for the numbers

```
83  typedef struct _bn_point_t
84  {
85      bigNum          x;
86      bigNum          y;
87      bigNum          z;
88  } bn_point_t;
89  typedef bn_point_t          *bigPoint;
90  typedef const bn_point_t    *pointConst;
91  typedef struct constant_point_t
92  {
93      bigConst        x;
94      bigConst        y;
95      bigConst        z;
96  } constant_point_t;
97  #define ECC_BITS    (MAX_ECC_KEY_BYTES * 8)
```

109      bn_point_t name##_
110  #define POINT_INITIALIZER(name)                                         \
111      BnInitializePoint(&name##_, (bigNum)&name##_x,                      \
112                      (bigNum)&name##_y, (bigNum)&name##_z)
113  #define POINT_INITIALIZED(name, initValue)                              \
114      POINT_INSTANCE(name, MAX_ECC_KEY_BITS);                             \
115      bigPoint             name = BnPointFrom2B(                          \
116                                      POINT_INITIALIZER(name),            \
117                                      initValue)
118  #define POINT_VAR(name, bits)                                           \
119      POINT_INSTANCE (name, bits);                                        \
120      bigPoint            name = POINT_INITIALIZER(name)
121  #define POINT(name)        POINT_VAR(name, MAX_ECC_KEY_BITS)
```

Structure for the curve parameters. This is an analog to the TPMS_ALGORITHM_DETAIL_ECC

```
122  typedef struct
123  {
124      bigConst             prime;     // a prime number
125      bigConst             order;     // the order of the curve
126      bigConst             h;         // cofactor
127      bigConst             a;         // linear coefficient
128      bigConst             b;         // constant term
129      constant_point_t     base;      // base point
130  } ECC_CURVE_DATA;
```

Access macros for the ECC_CURVE structure. The parameter *C* is a pointer to an ECC_CURVE_DATA structure. In some libraries, the curve structure contains a pointer to an ECC_CURVE_DATA structure as well as some other bits. For those cases, the AccessCurveData() macro is used in the code to first get the pointer to the ECC_CURVE_DATA for access. In some cases, the macro does noting.

```
131  #define CurveGetPrime(C)     ((C)->prime)
132  #define CurveGetOrder(C)     ((C)->order)
133  #define CurveGetCofactor(C)  ((C)->h)
134  #define CurveGet_a(C)        ((C)->a)
135  #define CurveGet_b(C)        ((C)->b)
136  #define CurveGetG(C)         ((pointConst)&((C)->base))
137  #define CurveGetGx(C)        ((C)->base.x)
138  #define CurveGetGy(C)        ((C)->base.y)
```

Convert bytes in initializers according to the endianess of the system. This is used for CryptEccData.c.

```
139  #define     BIG_ENDIAN_BYTES_TO_UINT32(a, b, c, d)                      \
140              (    ((UINT32)(a) << 24)                                    \
141              +    ((UINT32)(b) << 16)                                    \
142              +    ((UINT32)(c) << 8)                                     \
143              +    ((UINT32)(d))                                          \
144              )
145  #define     BIG_ENDIAN_BYTES_TO_UINT64(a, b, c, d, e, f, g, h)          \
146              (    ((UINT64)(a) << 56)                                    \
147              +    ((UINT64)(b) << 48)                                    \
148              +    ((UINT64)(c) << 40)                                    \
149              +    ((UINT64)(d) << 32)                                    \
```

 Copyright © TCG 2006-2020

```
150             +    ((UINT64)(e) << 24)                                    \
151             +    ((UINT64)(f) << 16)                                    \
152             +    ((UINT64)(g) << 8)                                     \
153             +    ((UINT64)(h))                                          \
154             )
155 #ifndef RADIX_BYTES
156 #   if RADIX_BITS == 32

10.1.2 CryptEcc.h

10.1.2.1 Introduction

This file contains structure definitions used for ECC. The structures in this file are only used internally. The ECC-related structures that cross the TPM interface are defined in TpmTypes.h

```
1   #ifndef _CRYPT_ECC_H
2   #define _CRYPT_ECC_H
```

10.1.2.2 Structures

This is used to define the macro that may or may not be in the data set for the curve (CryptEccData.c). If there is a mismatch, the compiler will warn that there is to much/not enough initialization data in the curve. The macro is used because not all versions of the CryptEccData.c need the curve name.

```
3   #ifdef NAMED_CURVES
4   #define CURVE_NAME(a) , a
5   #define CURVE_NAME_DEF const char *name;
6   #else
7   #  define CURVE_NAME(a)
8   #  define CURVE_NAME_DEF
9   #endif
10  typedef struct ECC_CURVE
11  {
12      const TPM_ECC_CURVE          curveId;
13      const UINT16                 keySizeBits;
14      const TPMT_KDF_SCHEME        kdf;
15      const TPMT_ECC_SCHEME        sign;
16      const ECC_CURVE_DATA        *curveData; // the address of the curve data
17      const BYTE                  *OID;
18      CURVE_NAME_DEF
19  } ECC_CURVE;
20  extern const ECC_CURVE eccCurves[ECC_CURVE_COUNT];
21
22  #endif
```

10.1.3 CryptHash.h

10.1.3.1 Introduction

This header contains the hash structure definitions used in the TPM code to define the amount of space to be reserved for the hash state. This allows the TPM code to not have to import all of the symbols used by the hash computations. This lets the build environment of the TPM code not to have include the header files associated with the CryptoEngine() code.

```
1    #ifndef _CRYPT_HASH_H
2    #define _CRYPT_HASH_H
```

10.1.3.2 Hash-related Structures

```
3    union SMAC_STATES;
```

These definitions add the high-level methods for processing state that may be an SMAC

```
4    typedef void(* SMAC_DATA_METHOD)(
5        union SMAC_STATES       *state,
6        UINT32                   size,
7        const BYTE              *buffer
8        );
9    typedef UINT16(* SMAC_END_METHOD)(
10       union SMAC_STATES       *state,
11       UINT32                   size,
12       BYTE                    *buffer
13       );
14   typedef struct sequenceMethods {
15       SMAC_DATA_METHOD           data;
16       SMAC_END_METHOD            end;
17   } SMAC_METHODS;
18   #define SMAC_IMPLEMENTED (CC_MAC || CC_MAC_Start)
```

These definitions are here because the SMAC state is in the union of hash states.

```
19   typedef struct tpmCmacState {
20       TPM_ALG_ID              symAlg;
21       UINT16                  keySizeBits;
22       INT16                   bcount; // current count of bytes accumulated in IV
23       TPM2B_IV                iv;     // IV buffer
24       TPM2B_SYM_KEY           symKey;
25   } tpmCmacState_t;
26   typedef union SMAC_STATES {
27   #if ALG_CMAC
28       tpmCmacState_t          cmac;
29   #endif
30       UINT64                  pad;
31   } SMAC_STATES;
32   typedef struct SMAC_STATE {
33       SMAC_METHODS            smacMethods;
34       SMAC_STATES             state;
35   } SMAC_STATE;
36   typedef union
37   {
38   #if ALG_SHA1
39       tpmHashStateSHA1_t         Sha1;
40   #endif
41   #if ALG_SHA256
42       tpmHashStateSHA256_t       Sha256;
43   #endif
```

```
44   #if ALG_SHA384
45       tpmHashStateSHA384_t        Sha384;
46   #endif
47   #if ALG_SHA512
48       tpmHashStateSHA512_t        Sha512;
49   #endif
50   #if ALG_SM3_256
51       tpmHashStateSM3_256_t       Sm3_256;
52   #endif
53
54   // Additions for symmetric block cipher MAC
55   #if SMAC_IMPLEMENTED
56       SMAC_STATE                  smac;
57   #endif
58       // to force structure alignment to be no worse than HASH_ALIGNMENT
59   #if HASH_ALIGNMENT == 4
60       uint32_t              align;
61   #else
62       uint64_t              align;
63   #endif
64   } ANY_HASH_STATE;
65   typedef ANY_HASH_STATE *PANY_HASH_STATE;
66   typedef const ANY_HASH_STATE    *PCANY_HASH_STATE;
67   #define ALIGNED_SIZE(x, b) (((x) + (b) - 1) / (b)) * (b))
```

MAX_HASH_STATE_SIZE will change with each implementation. It is assumed that a hash state will not be larger than twice the block size plus some overhead (in this case, 16 bytes). The overall size needs to be as large as any of the hash contexts. The structure needs to start on an alignment boundary and be an even multiple of the alignment

```
68   #define MAX_HASH_STATE_SIZE ((2 * MAX_HASH_BLOCK_SIZE) + 16)
69   #define MAX_HASH_STATE_SIZE_ALIGNED                                    \
70                   ALIGNED_SIZE(MAX_HASH_STATE_SIZE, HASH_ALIGNMENT)
```

This is an aligned byte array that will hold any of the hash contexts.

```
71   typedef  ANY_HASH_STATE ALIGNED_HASH_STATE;
```

The header associated with the hash library is expected to define the methods which include the calling sequence. When not compiling CryptHash.c, the methods are not defined so we need placeholder functions for the structures

```
72   #ifndef HASH_START_METHOD_DEF
73   #   define HASH_START_METHOD_DEF    void (HASH_START_METHOD)(void)
74   #endif
75   #ifndef HASH_DATA_METHOD_DEF
76   #   define HASH_DATA_METHOD_DEF     void (HASH_DATA_METHOD)(void)
77   #endif
78   #ifndef HASH_END_METHOD_DEF
79   #   define HASH_END_METHOD_DEF      void (HASH_END_METHOD)(void)
80   #endif
81   #ifndef HASH_STATE_COPY_METHOD_DEF
82   #   define HASH_STATE_COPY_METHOD_DEF     void (HASH_STATE_COPY_METHOD)(void)
83   #endif
84   #ifndef  HASH_STATE_EXPORT_METHOD_DEF
85   #   define  HASH_STATE_EXPORT_METHOD_DEF   void (HASH_STATE_EXPORT_METHOD)(void)
86   #endif
87   #ifndef  HASH_STATE_IMPORT_METHOD_DEF
88   #   define  HASH_STATE_IMPORT_METHOD_DEF   void (HASH_STATE_IMPORT_METHOD)(void)
89   #endif
```

Define the prototypical function call for each of the methods. This defines the order in which the parameters are passed to the underlying function.

120         TPM2B_TYPE(SM3_256_DIGEST, SM3_256_DIGEST_SIZE);
121     #endif
```

When the TPM implements RSA, the hash-dependent OID pointers are part of the HASH_DEF. These macros conditionally add the OID reference to the HASH_DEF and the HASH_DEF_TEMPLATE.

```
122     #if ALG_RSA
123     #define PKCS1_HASH_REF    const BYTE   *PKCS1;
124     #define PKCS1_OID(NAME)   , OID_PKCS1_##NAME
125     #else
126     #define PKCS1_HASH_REF
127     #define PKCS1_OID(NAME)
128     #endif
```

When the TPM implements ECC, the hash-dependent OID pointers are part of the HASH_DEF. These macros conditionally add the OID reference to the HASH_DEF and the HASH_DEF_TEMPLATE.

```
129     #if ALG_ECDSA
130     #define ECDSA_HASH_REF     const BYTE   *ECDSA;
131     #define ECDSA_OID(NAME)   , OID_ECDSA_##NAME
132     #else
133     #define ECDSA_HASH_REF
134     #define ECDSA_OID(NAME)
135     #endif
136     typedef const struct HASH_DEF
137     {
138         HASH_METHODS            method;
139         uint16_t                blockSize;
140         uint16_t                digestSize;
141         uint16_t                contextSize;
142         uint16_t                hashAlg;
143         const BYTE             *OID;
144         PKCS1_HASH_REF         // PKCS1 OID
145         ECDSA_HASH_REF         // ECDSA OID
```

```
146     } HASH_DEF, *PHASH_DEF;
```

Macro to fill in the HASH_DEF for an algorithm. For SHA1, the instance would be: HASH_DEF_TEMPLATE(Sha1, SHA1) This handles the difference in capitalization for the various pieces.

```
147     #define HASH_DEF_TEMPLATE(HASH, Hash)                                          \
148         HASH_DEF    Hash##_Def= {                                               \
149                         {(HASH_START_METHOD *)&tpmHashStart_##HASH,             \
150                          (HASH_DATA_METHOD *)&tpmHashData_##HASH,               \
151                          (HASH_END_METHOD *)&tpmHashEnd_##HASH,                 \
152                          (HASH_STATE_COPY_METHOD *)&tpmHashStateCopy_##HASH,    \
153                          (HASH_STATE_EXPORT_METHOD *)&tpmHashStateExport_##HASH, \
154                          (HASH_STATE_IMPORT_METHOD *)&tpmHashStateImport_##HASH, \
155                         },                                                      \
156                         HASH##_BLOCK_SIZE,     /*block size */                  \
157                         HASH##_DIGEST_SIZE,    /*data size */                   \
158                         sizeof(tpmHashState##HASH##_t),                         \
159                         TPM_ALG_##HASH, OID_##HASH                              \
160                         PKCS1_OID(HASH) ECDSA_OID(HASH)};
```

These definitions are for the types that can be in a hash state structure. These types are used in the cryptographic utilities. This is a define rather than an enum so that the size of this field can be explicit.

```
161     typedef BYTE    HASH_STATE_TYPE;
162     #define HASH_STATE_EMPTY        ((HASH_STATE_TYPE) 0)
163     #define HASH_STATE_HASH         ((HASH_STATE_TYPE) 1)
164     #define HASH_STATE_HMAC         ((HASH_STATE_TYPE) 2)
165     #if CC_MAC || CC_MAC_Start
166     #define HASH_STATE_SMAC         ((HASH_STATE_TYPE) 3)
167     #endif
```

This is the structure that is used for passing a context into the hashing functions. It should be the same size as the function context used within the hashing functions. This is checked when the hash function is initialized. This version uses a new layout for the contexts and a different definition. The state buffer is an array of HASH_UNIT values so that a decent compiler will put the structure on a HASH_UNIT boundary. If the structure is not properly aligned, the code that manipulates the structure will copy to a properly aligned structure before it is used and copy the result back. This just makes things slower.

NOTE: This version of the state had the pointer to the update method in the state. This is to allow the SMAC functions to use the same structure without having to replicate the entire HASH_DEF structure.

```
168     typedef struct _HASH_STATE
169     {
170         HASH_STATE_TYPE          type;               // type of the context
171         TPM_ALG_ID               hashAlg;
172         PHASH_DEF                def;
173         ANY_HASH_STATE           state;
174     } HASH_STATE, *PHASH_STATE;
175     typedef const HASH_STATE *PCHASH_STATE;
```

10.1.3.3 HMAC State Structures

An HMAC_STATE structure contains an opaque HMAC stack state. A caller would use this structure when performing incremental HMAC operations. This structure contains a hash state and an HMAC key and allows slightly better stack optimization than adding an HMAC key to each hash state.

```
176     typedef struct hmacState
177     {
178         HASH_STATE           hashState;          // the hash state
179         TPM2B_HASH_BLOCK     hmacKey;            // the HMAC key
180     } HMAC_STATE, *PHMAC_STATE;
```

This is for the external hash state. This implementation assumes that the size of the exported hash state is no larger than the internal hash state.

```
181 typedef struct
182 {
183     BYTE                     buffer[sizeof(HASH_STATE)];
184 } EXPORT_HASH_STATE, *PEXPORT_HASH_STATE;
185 typedef const EXPORT_HASH_STATE *PCEXPORT_HASH_STATE;
186 #endif //  _CRYPT_HASH_H
```

10.1.4 CryptRand.h

10.1.4.1 Introduction

This file contains constant definition shared by CryptUtil() and the parts of the Crypto Engine.

```
1   #ifndef _CRYPT_RAND_H
2   #define _CRYPT_RAND_H
```

10.1.4.2 DRBG Structures and Defines

Values and structures for the random number generator. These values are defined in this header file so that the size of the RNG state can be known to TPM.lib. This allows the allocation of some space in NV memory for the state to be stored on an orderly shutdown. The DRBG based on a symmetric block cipher is defined by three values,

a) the key size

b) the block size (the IV size)

c) the symmetric algorithm

```
3   #define DRBG_KEY_SIZE_BITS       AES_MAX_KEY_SIZE_BITS
4   #define DRBG_IV_SIZE_BITS        (AES_MAX_BLOCK_SIZE * 8)
5   #define DRBG_ALGORITHM           TPM_ALG_AES
6   typedef tpmKeyScheduleAES      DRBG_KEY_SCHEDULE;
7   #define DRBG_ENCRYPT_SETUP(key, keySizeInBits, schedule)        \
8               TpmCryptSetEncryptKeyAES(key, keySizeInBits, schedule)
9   #define DRBG_ENCRYPT(keySchedule, in, out)                      \
10              TpmCryptEncryptAES(SWIZZLE(keySchedule, in, out))
11  #if     ((DRBG_KEY_SIZE_BITS % RADIX_BITS) != 0) \
12      || ((DRBG_IV_SIZE_BITS % RADIX_BITS) != 0)
13  #error "Key size and IV for DRBG must be even multiples of the radix"
14  #endif
15  #if (DRBG_KEY_SIZE_BITS % DRBG_IV_SIZE_BITS) != 0
16  #error "Key size for DRBG must be even multiple of the cypher block size"
17  #endif
```

Derived values

```
18  #define DRBG_MAX_REQUESTS_PER_RESEED (1 << 48)
19  #define DRBG_MAX_REQEST_SIZE (1 << 32)
20  #define pDRBG_KEY(seed)     ((DRBG_KEY *)&(((BYTE *)(seed))[0]))
21  #define pDRBG_IV(seed)      ((DRBG_IV *)&(((BYTE *)(seed))[DRBG_KEY_SIZE_BYTES]))
22  #define DRBG_KEY_SIZE_WORDS      (BITS_TO_CRYPT_WORDS(DRBG_KEY_SIZE_BITS))
23  #define DRBG_KEY_SIZE_BYTES      (DRBG_KEY_SIZE_WORDS * RADIX_BYTES)
24  #define DRBG_IV_SIZE_WORDS       (BITS_TO_CRYPT_WORDS(DRBG_IV_SIZE_BITS))
25  #define DRBG_IV_SIZE_BYTES       (DRBG_IV_SIZE_WORDS * RADIX_BYTES)
26  #define DRBG_SEED_SIZE_WORDS     (DRBG_KEY_SIZE_WORDS + DRBG_IV_SIZE_WORDS)

10.1.6 CryptTest.h

This file contains constant definitions used for self-test.

```
1   #ifndef _CRYPT_TEST_H
2   #define _CRYPT_TEST_H
```

This is the definition of a bit array with one bit per algorithm.

NOTE: Since bit numbering starts at zero, when ALG_LAST_VALUE is a multiple of 8, ALGORITHM_VECTOR will need to have byte for the single bit in the last byte. So, for example, when ALG_LAST_VECTOR is 8, ALGORITHM_VECTOR will need 2 bytes.

```
3   #define ALGORITHM_VECTOR_BYTES  ((ALG_LAST_VALUE + 8) / 8)
4   typedef BYTE    ALGORITHM_VECTOR[ALGORITHM_VECTOR_BYTES];
5   #ifdef  TEST_SELF_TEST
6   LIB_EXPORT    extern  ALGORITHM_VECTOR    LibToTest;
7   #endif
8
9   // This structure is used to contain self-test tracking information for the
10  // cryptographic modules. Each of the major modules is given a 32-bit value in
11  // which it may maintain its own self test information. The convention for this
12  // state is that when all of the bits in this structure are 0, all functions need
13  // to be tested.
14  typedef struct
15  {
16      UINT32      rng;
17      UINT32      hash;
18      UINT32      sym;

10.1.10 SelfTest.h

10.1.10.1 Introduction

This file contains the structure definitions for the self-test. It also contains macros for use when the self-test is implemented.

```
1     #ifndef                      _SELF_TEST_H_
2     #define                      _SELF_TEST_H_
```

10.1.10.2 Defines

Was typing this a lot

```
3     #define SELF_TEST_FAILURE   FAIL(FATAL_ERROR_SELF_TEST)
```

Use the definition of key sizes to set algorithm values for key size.

```
4     #define AES_ENTRIES (AES_128 + AES_192 + AES_256)
5     #define SM4_ENTRIES (SM4_128)
6     #define CAMELLIA_ENTRIES (CAMELLIA_128 + CAMELLIA_192 + CAMELLIA_256)
7     #define TDES_ENTRIES (TDES_128 + TDES_192)
8     #define NUM_SYMS     (AES_ENTRIES + SM4_ENTRIES + CAMELLIA_ENTRIES + TDES_ENTRIES)
9     typedef UINT32       SYM_INDEX;
```

These two defines deal with the fact that the TPM_ALG_ID table does not delimit the symmetric mode values with a TPM_SYM_MODE_FIRST and TPM_SYM_MODE_LAST

```
10    #define TPM_SYM_MODE_FIRST        ALG_CTR_VALUE
11    #define TPM_SYM_MODE_LAST         ALG_ECB_VALUE
```

 Copyright © TCG 2006-2020

```
12  #define NUM_SYM_MODES    (TPM_SYM_MODE_LAST - TPM_SYM_MODE_FIRST + 1)
```

Define a type to hold a bit vector for the modes.

```
13  #if NUM_SYM_MODES <= 0
14  #error  "No symmetric modes implemented"
15  #elif NUM_SYM_MODES <= 8
16  typedef BYTE    SYM_MODES;
17  #elif NUM_SYM_MODES <= 16
18  typedef UINT16  SYM_MODES;
19  #elif NUM_SYM_MODES <= 32
20  typedef UINT32  SYM_MODES;
21  #else
22  #error "Too many symmetric modes"
23  #endif
24  typedef struct SYMMETRIC_TEST_VECTOR {
25      const TPM_ALG_ID     alg;                  // the algorithm
26      const UINT16         keyBits;              // bits in the key
27      const BYTE          *key;                  // The test key
28      const UINT32         ivSize;               // block size of the algorithm
29      const UINT32         dataInOutSize;        // size  to encrypt/decrypt
30      const BYTE          *dataIn;               // data to encrypt
31      const BYTE          *dataOut[NUM_SYM_MODES];// data to decrypt
32  } SYMMETRIC_TEST_VECTOR;
33  #if ALG_SHA512
34  #       define  DEFAULT_TEST_HASH               ALG_SHA512_VALUE
35  #       define  DEFAULT_TEST_DIGEST_SIZE        SHA512_DIGEST_SIZE
36  #       define  DEFAULT_TEST_HASH_BLOCK_SIZE    SHA512_BLOCK_SIZE
37  #elif ALG_SHA384
38  #       define  DEFAULT_TEST_HASH               ALG_SHA384_VALUE
39  #       define  DEFAULT_TEST_DIGEST_SIZE        SHA384_DIGEST_SIZE
40  #       define  DEFAULT_TEST_HASH_BLOCK_SIZE    SHA384_BLOCK_SIZE
41  #elif ALG_SHA256
42  #       define  DEFAULT_TEST_HASH               ALG_SHA256_VALUE
43  #       define  DEFAULT_TEST_DIGEST_SIZE        SHA256_DIGEST_SIZE
44  #       define  DEFAULT_TEST_HASH_BLOCK_SIZE    SHA256_BLOCK_SIZE
45  #elif ALG_SHA1
46  #       define  DEFAULT_TEST_HASH               ALG_SHA1_VALUE
47  #       define  DEFAULT_TEST_DIGEST_SIZE        SHA1_DIGEST_SIZE
48  #       define  DEFAULT_TEST_HASH_BLOCK_SIZE    SHA1_BLOCK_SIZE
49  #endif
50  #endif      // _SELF_TEST_H_
```

10.1.11 SupportLibraryFunctionPrototypes_fp.h

10.1.11.1 Introduction

This file contains the function prototypes for the functions that need to be present in the selected math library. For each function listed, there should be a small stub function. That stub provides the interface between the TPM code and the support library. In most cases, the stub function will only need to do a format conversion between the TPM big number and the support library big number. The TPM big number format was chosen to make this relatively simple and fast.

Arithmetic operations return a BOOL to indicate if the operation completed successfully or not.

```
1  #ifndef SUPPORT_LIBRARY_FUNCTION_PROTOTYPES_H
2  #define SUPPORT_LIBRARY_FUNCTION_PROTOTYPES_H
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

10.1.11.2 SupportLibInit()

This function is called by CryptInit() so that necessary initializations can be performed on the cryptographic library.

```
3   LIB_EXPORT
4   int SupportLibInit(void);
```

10.1.11.3 MathLibraryCompatibililtyCheck()

This function is only used during development to make sure that the library that is being referenced is using the same size of data structures as the TPM.

```
5   BOOL
6   MathLibraryCompatibilityCheck(
7       void
8       );
```

10.1.11.4 BnModMult()

Does *op1* * *op2* and divide by *modulus* returning the remainder of the divide.

```
9   LIB_EXPORT BOOL
10  BnModMult(bigNum result, bigConst op1, bigConst op2, bigConst modulus);
```

10.1.11.5 BnMult()

Multiplies two numbers and returns the result

```
11  LIB_EXPORT BOOL
12  BnMult(bigNum result, bigConst multiplicand, bigConst multiplier);
```

10.1.11.6 BnDiv()

This function divides two *bigNum* values. The function returns FALSE if there is an error in the operation.

```
13  LIB_EXPORT BOOL
14  BnDiv(bigNum quotient, bigNum remainder,
15                        bigConst dividend, bigConst divisor);
```

10.1.11.7 BnMod()

```
16  #define BnMod(a, b)     BnDiv(NULL, (a), (a), (b))
```

10.1.11.8 BnGcd()

Get the greatest common divisor of two numbers. This function is only needed when the TPM implements RSA.

```
17  LIB_EXPORT BOOL
18  BnGcd(bigNum gcd, bigConst number1, bigConst number2);
```

 Copyright © TCG 2006-2020

10.1.11.9 BnModExp()

Do modular exponentiation using *bigNum* values. This function is only needed when the TPM implements RSA.

```
19 LIB_EXPORT BOOL
20 BnModExp(bigNum result, bigConst number,
21                              bigConst exponent, bigConst modulus);
```

10.1.11.10 BnModInverse()

Modular multiplicative inverse. This function is only needed when the TPM implements RSA.

```
22 LIB_EXPORT BOOL BnModInverse(bigNum result, bigConst number,
23                              bigConst modulus);
```

10.1.11.11 BnEccModMult()

This function does a point multiply of the form R = [d]S. A return of FALSE indicates that the result was the point at infinity. This function is only needed if the TPM supports ECC.

```
24 LIB_EXPORT BOOL
25 BnEccModMult(bigPoint R, pointConst S, bigConst d, bigCurve E);
```

10.1.11.12 BnEccModMult2()

This function does a point multiply of the form R = [d]S + [u]Q. A return of FALSE indicates that the result was the point at infinity. This function is only needed if the TPM supports ECC.

```
26 LIB_EXPORT BOOL
27 BnEccModMult2(bigPoint R, pointConst S, bigConst d,
28                              pointConst Q, bigConst u, bigCurve E);
```

10.1.11.13 BnEccAdd()

This function does a point add R = S + Q. A return of FALSE indicates that the result was the point at infinity. This function is only needed if the TPM supports ECC.

```
29 LIB_EXPORT BOOL
30 BnEccAdd(bigPoint R, pointConst S, pointConst Q, bigCurve E);
```

10.1.11.14 BnCurveInitialize()

This function is used to initialize the pointers of a *bnCurve_t* structure. The structure is a set of pointers to *bigNum* values. The curve-dependent values are set by a different function. This function is only needed if the TPM supports ECC.

```
31 LIB_EXPORT bigCurve
32 BnCurveInitialize(bigCurve E, TPM_ECC_CURVE curveId);
```

10.1.11.14.1 BnCurveFree()

This function will free the allocated components of the curve and end the frame in which the curve data exists

```
33 LIB_EXPORT void
34 BnCurveFree(bigCurve E);
35 #endif
```

10.1.12 SymmetricTestData.h

This is a vector for testing either encrypt or decrypt. The premise for decrypt is that the IV for decryption is the same as the IV for encryption. However, the *ivOut* value may be different for encryption and decryption. We will encrypt at least two blocks. This means that the chaining value will be used for each of the schemes (if any) and that implicitly checks that the chaining value is handled properly.

```
1   #if AES_128
2   const BYTE  key_AES128 [] = {

10.1.13 SymmetricTest.h

10.1.13.1 Introduction

This file contains the structures and data definitions for the symmetric tests. This file references the header file that contains the actual test vectors. This organization was chosen so that the program that is used to generate the test vector values does not have to also re-generate this data.

```
1   #ifndef     SELF_TEST_DATA
2   #error  "This file may only be included in AlgorithmTests.c"
3   #endif
4   #ifndef     _SYMMETRIC_TEST_H
5   #define     _SYMMETRIC_TEST_H
6   #include    "SymmetricTestData.h"
```

10.1.13.2 Symmetric Test Structures

```
7   const SYMMETRIC_TEST_VECTOR   c_symTestValues[NUM_SYMS + 1] = {
8   #if ALG_AES && AES_128

10.1.15 CryptSym.h

10.1.15.1 Introduction

This file contains the implementation of the symmetric block cipher modes allowed for a TPM. These functions only use the single block encryption functions of the selected symmetric cryptographic library.

10.1.15.2 Includes, Defines, and Typedefs

```
1   #ifndef CRYPT_SYM_H
2   #define CRYPT_SYM_H
3   typedef union tpmCryptKeySchedule_t {
4   #if ALG_AES
5       tpmKeyScheduleAES           AES;
6   #endif
7   #if ALG_SM4
8       tpmKeyScheduleSM4           SM4;
9   #endif
10  #if ALG_CAMELLIA
11      tpmKeyScheduleCAMELLIA      CAMELLIA;
12  #endif
13
14  #if ALG_TDES
15      tpmKeyScheduleTDES          TDES[3];
16  #endif
17  #if SYMMETRIC_ALIGNMENT == 8
18      uint64_t            alignment;
19  #else
20      uint32_t            alignment;
21  #endif
22  } tpmCryptKeySchedule_t;
```

Each block cipher within a library is expected to conform to the same calling conventions with three parameters (*keySchedule*, *in*, and *out*) in the same order. That means that all algorithms would use the same order of the same parameters. The code is written assuming the (*keySchedule*, *in*, and *out*) order. However, if the library uses a different order, the order can be changed with a SWIZZLE macro that puts the parameters in the correct order. Note that all algorithms have to use the same order and number of parameters because the code to build the calling list is common for each call to encrypt or decrypt with the algorithm chosen by setting a function pointer to select the algorithm that is used.

```
23  #   define ENCRYPT(keySchedule, in, out)                                  \
24        encrypt(SWIZZLE(keySchedule, in, out))
25  #   define DECRYPT(keySchedule, in, out)                                  \
26        decrypt(SWIZZLE(keySchedule, in, out))
```

Note that the macros rely on *encrypt* as local values in the functions that use these macros. Those parameters are set by the macro that set the key schedule to be used for the call.

```
27  #define ENCRYPT_CASE(ALG)                                                \
28      case TPM_ALG_##ALG:                                                  \
29          TpmCryptSetEncryptKey##ALG(key, keySizeInBits, &keySchedule.ALG); \
30          encrypt = (TpmCryptSetSymKeyCall_t)TpmCryptEncrypt##ALG;         \
31          break;
32  #define DECRYPT_CASE(ALG)                                                \
33      case TPM_ALG_##ALG:                                                  \
34          TpmCryptSetDecryptKey##ALG(key, keySizeInBits, &keySchedule.ALG); \
35          decrypt = (TpmCryptSetSymKeyCall_t)TpmCryptDecrypt##ALG;         \
36          break;
37  #if ALG_AES
38  #define ENCRYPT_CASE_AES    ENCRYPT_CASE(AES)
```

```
39  #define ENCRYPT_CASE_AES     DECRYPT_CASE(AES)
40  #else
41  #define ENCRYPT_CASE_AES
42  #define DECRYPT_CASE_AES
43  #endif
44  #if ALG_SM4
45  #define ENCRYPT_CASE_SM4     ENCRYPT_CASE(SM4)
46  #define DECRYPT_CASE_SM4     DECRYPT_CASE(SM4)
47  #else
48  #define ENCRYPT_CASE_SM4
49  #define DECRYPT_CASE_SM4
50  #endif
51  #if ALG_CAMELLIA
52  #define ENCRYPT_CASE_CAMELLIA     ENCRYPT_CASE(CAMELLIA)
53  #define DECRYPT_CASE_CAMELLIA     DECRYPT_CASE(CAMELLIA)
54  #else
55  #define ENCRYPT_CASE_CAMELLIA
56  #define DECRYPT_CASE_CAMELLIA
57  #endif
58  #if ALG_TDES
59  #define ENCRYPT_CASE_TDES     ENCRYPT_CASE(TDES)
60  #define DECRYPT_CASE_TDES     DECRYPT_CASE(TDES)
61  #else
62  #define ENCRYPT_CASE_TDES
63  #define DECRYPT_CASE_TDES
64  #endif
```

For each algorithm the case will either be defined or null.

```
65  #define     SELECT(direction)                                    \
66      switch(algorithm)                                            \
67      {                                                            \
68          direction##_CASE_AES                                     \
69          direction##_CASE_SM4                                     \
70          direction##_CASE_CAMELLIA                                \
71          direction##_CASE_TDES                                    \
72          default:                                                 \
73              FAIL(FATAL_ERROR_INTERNAL);                          \
74      }
75  #endif // CRYPT_SYM_H
```

10.1.16 OIDs.h

```
1  #ifndef _OIDS_H_
2  #define _OIDS_H_
```

All the OIDs in this file are defined as DER-encoded values with a leading tag 0x06 (ASN1_OBJECT_IDENTIFIER), followed by a single length byte. This allows the OID size to be determined by looking at octet[1] of the OID (total size is OID[1] + 2). These macros allow OIDs to be defined (or not) depending on whether the associated hash algorithm is implemented.

NOTE: When one of these macros is used, the NAME needs '_' on each side. The exception is when the macro is used for the hash OID when only a single _ is used.

```
3  #ifndef ALG_SHA1
4  #   define ALG_SHA1 NO
5  #endif
6  #if ALG_SHA1
7  #define SHA1_OID(NAME)    MAKE_OID(NAME##SHA1)
8  #else
9  #define SHA1_OID(NAME)

35  #define ASN1_CONSTRUCTED_SEQUENCE (ASN1_SEQUENCE + ASN1_CONSTRUCTED)
36  #define MAX_DEPTH               10  // maximum push depth for marshaling context.
```

10.1.18.4 Macros

10.1.18.4.1 Unmarshaling Macros

```
37  #ifndef VERIFY
38  #define VERIFY(_X_) {if(!(_X_)) goto Error; }
39  #endif
```

Checks the validity of the size making sure that there is no wrap around

```
40  #define CHECK_SIZE(context, length)                                     \
41          VERIFY(   (((length) + (context)->offset) >= (context)->offset)   \
42                 && (((length) + (context)->offset) <= (context)->size))
43  #define NEXT_OCTET(context) ((context)->buffer[(context)->offset++])
44  #define PEEK_NEXT(context) ((context)->buffer[(context)->offset])
```

10.1.18.4.2 Marshaling Macros

Marshaling works in reverse order. The offset is set to the top of the buffer and, as the buffer is filled, *offset* counts down to zero. When the full thing is encoded it can be moved to the top of the buffer. This happens when the last context is closed.

```
45  #define CHECK_SPACE(context, length)    VERIFY(context->offset > length)
```

10.1.18.5 Structures

```
46  typedef struct ASN1UnmarshalContext {
47      BYTE            *buffer;    // pointer to the buffer
48      INT16            size;      // size of the buffer (a negative number indicates
49                                  // a parsing failure).
50      INT16            offset;    // current offset into the buffer (a negative number
51                                  // indicates a parsing failure). Not used
52      BYTE             tag;       // The last unmarshaled tag
53  } ASN1UnmarshalContext;
54  typedef struct ASN1MarshalContext {
55      BYTE            *buffer;    // pointer to the start of the buffer
56      INT16            offset;    // place on the top where the last entry was added
57                                  // items are added from the bottom up.
58      INT16            end;       // the end offset of the current value
59      INT16            depth;     // how many pushed end values.
60      INT16            ends[MAX_DEPTH];
61  } ASN1MarshalContext;
62  #endif // _TPMASN1_H_
```

10.1.19 X509.h

10.1.19.1 Introduction

This file contains the macro and structure definitions for the X509 commands and functions.

```
1  #ifndef _X509_H_
2  #define _X509_H_
```

10.1.19.2 Includes

```
3  #include "Tpm.h"
4  #include "TpmASN1.h"
```

10.1.19.3 Defined Constants

10.1.19.3.1 X509 Application-specific types

```
5  #define X509_SELECTION          0xA0
6  #define X509_ISSUER_UNIQUE_ID   0xA1
7  #define X509_SUBJECT_UNIQUE_ID  0xA2
8  #define X509_EXTENSIONS         0xA3
```

These defines give the order in which values appear in the TBScertificate of an x.509 certificate. These values are used to index into an array of

```
9  #define ENCODED_SIZE_REF        0
10 #define VERSION_REF             (ENCODED_SIZE_REF + 1)
11 #define SERIAL_NUMBER_REF       (VERSION_REF + 1)
12 #define SIGNATURE_REF           (SERIAL_NUMBER_REF + 1)
13 #define ISSUER_REF              (SIGNATURE_REF + 1)
14 #define VALIDITY_REF            (ISSUER_REF + 1)
15 #define SUBJECT_KEY_REF         (VALIDITY_REF + 1)
16 #define SUBJECT_PUBLIC_KEY_REF  (SUBJECT_KEY_REF + 1)
17 #define EXTENSIONS_REF          (SUBJECT_PUBLIC_KEY_REF + 1)
18 #define REF_COUNT               (EXTENSIONS_REF + 1)
```

10.1.19.4 Structures

Used to access the fields of a TBSsignature some of which are in the *in_CertifyX509* structure and some of which are in the *out_CertifyX509* structure.

```
19 typedef struct stringRef
20 {
21     BYTE        *buf;
22     INT16        len;
23 } stringRef;
```

This is defined to avoid bit by bit comparisons within a UINT32

```
24 typedef union x509KeyUsageUnion {
25     TPMA_X509_KEY_USAGE     x509;
26     UINT32                  integer;
27 } x509KeyUsageUnion;
```

10.1.19.5 Global X509 Constants

These values are instanced by X509_spt.c and referenced by other X509-related files. This is the DER-encoded value for the Key Usage OID (2.5.29.15). This is the full OID, not just the numeric value

```
28 #define OID_KEY_USAGE_EXTENSION_VALUE  0x06, 0x03, 0x55, 0x1D, 0x0F
29 MAKE_OID(_KEY_USAGE_EXTENSION);
```

This is the DER-encoded value for the TCG-defined TPMA_OBJECT OID (2.23.133.10.1.1.1)

 Copyright © TCG 2006-2020

```
30 #define OID_TCG_TPMA_OBJECT_VALUE       0x06, 0x07, 0x67, 0x81, 0x05, 0x0a, 0x01,   \
31                                         0x01, 0x01
32 MAKE_OID(_TCG_TPMA_OBJECT);
33 #ifdef _X509_SPT_
```

If a bit is SET in KEY_USAGE_SIGN is also SET in *keyUsagem* then the associated key has to have *sign* SET.

```
34 const x509KeyUsageUnion KEY_USAGE_SIGN =
35 { TPMA_X509_KEY_USAGE_INITIALIZER(
36     /* bits_at_0        */ 0, /* decipheronly    */ 0,  /* encipheronly   */ 0,
37     /* crlsign          */ 1, /* keycertsign     */ 1,  /* keyagreement   */ 0,

Define the 2B structure that would hold any hash block

```
299     TPM2B_TYPE(MAX_HASH_BLOCK, MAX_HASH_BLOCK_SIZE);
```

Following typedef is for some old code

```
300     typedef TPM2B_MAX_HASH_BLOCK    TPM2B_HASH_BLOCK;
```

Additional symmetric constants

```
301     #define MAX_SYM_KEY_BITS        \
302                 (MAX(AES_MAX_KEY_SIZE_BITS,      MAX(CAMELLIA_MAX_KEY_SIZE_BITS,       \
303                  MAX(SM4_MAX_KEY_SIZE_BITS,      MAX(TDES_MAX_KEY_SIZE_BITS,           \
304                  0)))))
305     #define MAX_SYM_KEY_BYTES       ((MAX_SYM_KEY_BITS + 7) / 8)
306     #define MAX_SYM_BLOCK_SIZE      \

10.2 Source

10.2.1 AlgorithmTests.c

10.2.1.1 Introduction

This file contains the code to perform the various self-test functions.

NOTE: In this implementation, large local variables are made static to minimize stack usage, which is critical for stack-constrained platforms.

10.2.1.2 Includes and Defines

```
1   #include     "Tpm.h"
2   #define      SELF_TEST_DATA
3   #if SELF_TEST
```

These includes pull in the data structures. They contain data definitions for the various tests.

```
4   #include     "SelfTest.h"
5   #include     "SymmetricTest.h"
6   #include     "RsaTestData.h"
7   #include     "EccTestData.h"
8   #include     "HashTestData.h"
9   #include     "KdfTestData.h"
10  #define TEST_DEFAULT_TEST_HASH(vector)                                    \
11              if(TEST_BIT(DEFAULT_TEST_HASH, g_toTest))                     \
12                  TestHash(DEFAULT_TEST_HASH, vector);
```

Make sure that the algorithm has been tested

```
13  #define CLEAR_BOTH(alg)      {    CLEAR_BIT(alg, *toTest);                \
14                                    if(toTest != &g_toTest)                 \
15                                        CLEAR_BIT(alg, g_toTest); }
16  #define SET_BOTH(alg)      {    SET_BIT(alg, *toTest);                    \
17                                    if(toTest != &g_toTest)                 \
18                                        SET_BIT(alg, g_toTest); }
19  #define TEST_BOTH(alg)        ((toTest != &g_toTest)                      \
20                               ? TEST_BIT(alg, *toTest) || TEST_BIT(alg, g_toTest)   \
21                               : TEST_BIT(alg, *toTest))
```

Can only cancel if doing a list.

```
22  #define CHECK_CANCELED                                                    \
23      if(_plat__IsCanceled() && toTest != &g_toTest)                        \
24          return TPM_RC_CANCELED;
```

10.2.1.3 Hash Tests

10.2.1.3.1 Description

The hash test does a known-value HMAC using the specified hash algorithm.

10.2.1.3.2 TestHash()

The hash test function.

```
25    static TPM_RC
26    TestHash(
27        TPM_ALG_ID            hashAlg,
28        ALGORITHM_VECTOR      *toTest
29        )
30    {
31        static TPM2B_DIGEST       computed;  // value computed
32        static HMAC_STATE         state;
33        UINT16                    digestSize;
34        const TPM2B              *testDigest = NULL;
35    //    TPM2B_TYPE(HMAC_BLOCK, DEFAULT_TEST_HASH_BLOCK_SIZE);
36
37        pAssert(hashAlg != ALG_NULL_VALUE);
38        switch(hashAlg)
39        {
40    #if ALG_SHA1

10.2.1.4 Symmetric Test Functions

10.2.1.4.1 MakeIv()

Internal function to make the appropriate IV depending on the mode.

```
 90  static UINT32
 91  MakeIv(
 92      TPM_ALG_ID    mode,     // IN: symmetric mode
 93      UINT32        size,     // IN: block size of the algorithm
 94      BYTE         *iv        // OUT: IV to fill in
 95      )
 96  {
 97      BYTE          i;
 98
 99      if(mode == ALG_ECB_VALUE)
100          return 0;
101      if(mode == ALG_CTR_VALUE)
102      {
103          // The test uses an IV that has 0xff in the last byte
104          for(i = 1; i <= size; i++)
105              *iv++ = 0xff - (BYTE)(size - i);
106      }
107      else
108      {
109          for(i = 0; i < size; i++)
110              *iv++ = i;
111      }
112      return size;
113  }
```

10.2.1.4.2 TestSymmetricAlgorithm()

Function to test a specific algorithm, key size, and mode.

```
114  static void
115  TestSymmetricAlgorithm(
116      const SYMMETRIC_TEST_VECTOR     *test,          //
117      TPM_ALG_ID                       mode           //
118      )
119  {
120      static BYTE                  encrypted[MAX_SYM_BLOCK_SIZE * 2];
121      static BYTE                  decrypted[MAX_SYM_BLOCK_SIZE * 2];
122      static TPM2B_IV              iv;
123  //
124      // Get the appropriate IV
125      iv.t.size = (UINT16)MakeIv(mode, test->ivSize, iv.t.buffer);
126
127      // Encrypt known data
128      CryptSymmetricEncrypt(encrypted, test->alg, test->keyBits, test->key, &iv,
129                            mode, test->dataInOutSize, test->dataIn);
130      // Check that it matches the expected value
131      if(!MemoryEqual(encrypted, test->dataOut[mode - ALG_CTR_VALUE],
132                      test->dataInOutSize))
133          SELF_TEST_FAILURE;
134      // Reinitialize the iv for decryption
135      MakeIv(mode, test->ivSize, iv.t.buffer);
136      CryptSymmetricDecrypt(decrypted, test->alg, test->keyBits, test->key, &iv,
137                            mode, test->dataInOutSize,
138                            test->dataOut[mode - ALG_CTR_VALUE]);
139      // Make sure that it matches what we started with
140      if(!MemoryEqual(decrypted, test->dataIn, test->dataInOutSize))
141          SELF_TEST_FAILURE;
```

```
142 }
```

10.2.1.4.3 AllSymsAreDone()

Checks if both symmetric algorithms have been tested. This is put here so that addition of a symmetric algorithm will be relatively easy to handle

Return Value	Meaning
TRUE(1)	all symmetric algorithms tested
FALSE(0)	not all symmetric algorithms tested

```
143 static BOOL
144 AllSymsAreDone(
145     ALGORITHM_VECTOR        *toTest
146     )
147 {
148     return (!TEST_BOTH(ALG_AES_VALUE) && !TEST_BOTH(ALG_SM4_VALUE));
149 }
```

10.2.1.4.4 AllModesAreDone()

Checks if all the modes have been tested

Return Value	Meaning
TRUE(1)	all modes tested
FALSE(0)	all modes not tested

```
150 static BOOL
151 AllModesAreDone(
152     ALGORITHM_VECTOR            *toTest
153     )
154 {
155     TPM_ALG_ID                  alg;
156     for(alg = TPM_SYM_MODE_FIRST; alg <= TPM_SYM_MODE_LAST; alg++)
157         if(TEST_BOTH(alg))
158             return FALSE;
159     return TRUE;
160 }
```

10.2.1.4.5 TestSymmetric()

If *alg* is a symmetric block cipher, then all of the modes that are selected are tested. If *alg* is a mode, then all algorithms of that mode are tested.

```
161 static TPM_RC
162 TestSymmetric(
163     TPM_ALG_ID                   alg,
164     ALGORITHM_VECTOR            *toTest
165     )
166 {
167     SYM_INDEX                    index;
168     TPM_ALG_ID                   mode;
169 //
170     if(!TEST_BIT(alg, *toTest))
171         return TPM_RC_SUCCESS;
172     if(alg == ALG_AES_VALUE || alg == ALG_SM4_VALUE || alg == ALG_CAMELLIA_VALUE)
173     {
```

 Copyright © TCG 2006-2020

```
174             // Will test the algorithm for all modes and key sizes
175             CLEAR_BOTH(alg);
176
177             // A test this algorithm for all modes
178             for(index = 0; index < NUM_SYMS; index++)
179             {
180                 if(c_symTestValues[index].alg == alg)
181                 {

```

10.2.1.5 RSA Tests

```
235     #if ALG_RSA
```

 Copyright © TCG 2006-2020

10.2.1.5.1 Introduction

The tests are for public key only operations and for private key operations. Signature verification and encryption are public key operations. They are tested by using a KVT. For signature verification, this means that a known good signature is checked by CryptRsaValidateSignature(). If it fails, then the TPM enters failure mode. For encryption, the TPM encrypts known values using the selected scheme and checks that the returned value matches the expected value.

For private key operations, a full scheme check is used. For a signing key, a known key is used to sign a known message. Then that signature is verified. since the signature may involve use of random values, the signature will be different each time and we can't always check that the signature matches a known value. The same technique is used for decryption (RSADP/RSAEP).

When an operation uses the public key and the verification has not been tested, the TPM will do a KVT.

The test for the signing algorithm is built into the call for the algorithm

10.2.1.5.2 RsaKeyInitialize()

The test key is defined by a public modulus and a private prime. The TPM's RSA code computes the second prime and the private exponent.

```
236  static void
237  RsaKeyInitialize(
238      OBJECT          *testObject
239      )
240  {
241      MemoryCopy2B(&testObject->publicArea.unique.rsa.b, (P2B)&c_rsaPublicModulus,
242                   sizeof(c_rsaPublicModulus));
243      MemoryCopy2B(&testObject->sensitive.sensitive.rsa.b, (P2B)&c_rsaPrivatePrime,
244                   sizeof(testObject->sensitive.sensitive.rsa.t.buffer));
245      testObject->publicArea.parameters.rsaDetail.keyBits = RSA_TEST_KEY_SIZE * 8;
246      // Use the default exponent
247      testObject->publicArea.parameters.rsaDetail.exponent = 0;
248  }
```

10.2.1.5.3 TestRsaEncryptDecrypt()

These tests are for a public key encryption that uses a random value.

```
249  static TPM_RC
250  TestRsaEncryptDecrypt(
251      TPM_ALG_ID           scheme,            // IN: the scheme
252      ALGORITHM_VECTOR    *toTest             //
253      )
254  {
255      static TPM2B_PUBLIC_KEY_RSA      testInput;
256      static TPM2B_PUBLIC_KEY_RSA      testOutput;
257      static OBJECT                    testObject;
258      const TPM2B_RSA_TEST_KEY        *kvtValue = NULL;
259      TPM_RC                           result = TPM_RC_SUCCESS;
260      const TPM2B                     *testLabel = NULL;
261      TPMT_RSA_DECRYPT                 rsaScheme;
262  //
263      // Don't need to initialize much of the test object
264      RsaKeyInitialize(&testObject);
265      rsaScheme.scheme = scheme;
266      rsaScheme.details.anySig.hashAlg = DEFAULT_TEST_HASH;
267      CLEAR_BOTH(scheme);
268      CLEAR_BOTH(ALG_NULL_VALUE);
269      if(scheme == ALG_NULL_VALUE)
270      {
```

10.2.1.5.4 TestRsaSignAndVerify()

This function does the testing of the RSA sign and verification functions. This test does a KVT.

```
346    static TPM_RC
347    TestRsaSignAndVerify(
348        TPM_ALG_ID                 scheme,
349        ALGORITHM_VECTOR          *toTest
350        )
351    {
352        TPM_RC                         result = TPM_RC_SUCCESS;
353        static OBJECT                  testObject;
354        static TPM2B_DIGEST            testDigest;
355        static TPMT_SIGNATURE          testSig;
356
357        // Do a sign and signature verification.
358        // RSASSA:
359        // This is a signing scheme according to PKCS#1-v2.1 8.2. It does not
360        // use random data so there is a KVT for the signing operation. On
361        // first use of the scheme for signing, use the TPM's RSA key to
362        // sign a portion of c_RsaTestData and compare the results to c_RsassaKvt. Then
363        // decrypt the data to see that it matches the starting value. This verifies
364        // the signature with a KVT
365
366        // Clear the bits indicating that the function has not been checked. This is to
367        // prevent looping
368        CLEAR_BOTH(scheme);
369        CLEAR_BOTH(ALG_NULL_VALUE);
370        CLEAR_BOTH(ALG_RSA_VALUE);
371
372        RsaKeyInitialize(&testObject);
373        memcpy(testDigest.t.buffer, (BYTE *)c_RsaTestValue, DEFAULT_TEST_DIGEST_SIZE);
374        testDigest.t.size = DEFAULT_TEST_DIGEST_SIZE;

632     #endif // ALG_ECC
```

10.2.1.6.7 TestAlgorithm()

Dispatches to the correct test function for the algorithm or gets a list of testable algorithms.

If *toTest* is not NULL, then the test decisions are based on the algorithm selections in *toTest*. Otherwise, *g_toTest* is used. When bits are clear in *g_toTest* they will also be cleared *toTest*.

If there doesn't happen to be a test for the algorithm, its associated bit is quietly cleared.

If *alg* is zero (TPM_ALG_ERROR), then the *toTest* vector is cleared of any bits for which there is no test (i.e. no tests are actually run but the vector is cleared).

NOTE: *toTest* will only ever have bits set for implemented algorithms but *alg* can be anything.

Error Returns	Meaning
TPM_RC_CANCELED	test was canceled

```
633     LIB_EXPORT
634     TPM_RC
635     TestAlgorithm(
636         TPM_ALG_ID                  alg,
637         ALGORITHM_VECTOR           *toTest
638         )
639     {
640         TPM_ALG_ID                 first = (alg == ALG_ERROR_VALUE) ? ALG_FIRST_VALUE : alg;

10.2.2 BnConvert.c

10.2.2.1 Introduction

This file contains the basic conversion functions that will convert TPM2B to/from the internal format. The internal format is a *bigNum*,

10.2.2.2 Includes

```
1   #include "Tpm.h"
```

10.2.2.3 Functions

10.2.2.3.1 BnFromBytes()

This function will convert a big-endian byte array to the internal number format. If bn is NULL, then the output is NULL. If bytes is null or the required size is 0, then the output is set to zero

```
2   LIB_EXPORT bigNum
3   BnFromBytes(
4       bigNum              bn,
5       const BYTE         *bytes,
6       NUMBYTES            nBytes
7       )
8   {
9       const BYTE         *pFrom; // 'p' points to the least significant bytes of source
10      BYTE               *pTo;   // points to least significant bytes of destination
11      crypt_uword_t       size;
12  //
13
14      size = (bytes != NULL) ? BYTES_TO_CRYPT_WORDS(nBytes) : 0;
15
16      // If nothing in, nothing out
17      if(bn == NULL)
18          return NULL;
19
20      // make sure things fit
21      pAssert(BnGetAllocated(bn) >= size);
22
23      if(size > 0)
24      {
25          // Clear the topmost word in case it is not filled with data
26          bn->d[size - 1] = 0;
27          // Moving the input bytes from the end of the list (LSB) end
28          pFrom = bytes + nBytes - 1;
29          // To the LS0 of the LSW of the bigNum.
30          pTo = (BYTE *)bn->d;
31          for(; nBytes != 0; nBytes--)
32              *pTo++ = *pFrom--;
33          // For a little-endian machine, the conversion is a straight byte
34          // reversal. For a big-endian machine, we have to put the words in
35          // big-endian byte order
36  #if BIG_ENDIAN_TPM
37          {
38              crypt_word_t   t;
39              for(t = (crypt_word_t)size - 1; t >= 0; t--)
40                  bn->d[t] = SWAP_CRYPT_WORD(bn->d[t]);
41          }
42  #endif
43      }
```

```
44      BnSetTop(bn, size);
45      return bn;
46  }
```

10.2.2.3.2 BnFrom2B()

Convert an TPM2B to a BIG_NUM. If the input value does not exist, or the output does not exist, or the input will not fit into the output the function returns NULL

```
47  LIB_EXPORT bigNum
48  BnFrom2B(
49      bigNum           bn,          // OUT:
50      const TPM2B     *a2B          // IN: number to convert
51      )
52  {
53      if(a2B != NULL)
54          return BnFromBytes(bn, a2B->buffer, a2B->size);
55      // Make sure that the number has an initialized value rather than whatever
56      // was there before
57      BnSetTop(bn, 0);    // Function accepts NULL
58      return NULL;
59  }
```

10.2.2.3.3 BnFromHex()

Convert a hex string into a *bigNum*. This is primarily used in debugging.

```
60  LIB_EXPORT bigNum
61  BnFromHex(
62      bigNum          bn,          // OUT:
63      const char      *hex         // IN:
64      )
65  {
66  #define FromHex(a)  ((a) - (((a) > 'a') ? ('a' + 10)                          \
67                                         : ((a) > 'A') ? ('A' - 10) : '0'))
68      unsigned             i;
69      unsigned             wordCount;
70      const char          *p;
71      BYTE                *d = (BYTE *)&(bn->d[0]);
72  //
73      pAssert(bn && hex);
74      i = (unsigned)strlen(hex);
75      wordCount = BYTES_TO_CRYPT_WORDS((i + 1) / 2);
76      if((i == 0) || (wordCount >= BnGetAllocated(bn)))
77          BnSetWord(bn, 0);
78      else
79      {
80          bn->d[wordCount - 1] = 0;
81          p = hex + i - 1;
82          for(;i > 1; i -= 2)
83          {
84              BYTE a;
85              a = FromHex(*p);
86              p--;
87              *d++ = a + (FromHex(*p) << 4);
88              p--;
89          }
90          if(i == 1)
91              *d = FromHex(*p);
92      }
93  #if !BIG_ENDIAN_TPM
94      for(i = 0; i < wordCount; i++)
95          bn->d[i] = SWAP_CRYPT_WORD(bn->d[i]);
```

```
 96  #endif // BIG_ENDIAN_TPM
 97      BnSetTop(bn, wordCount);
 98      return bn;
 99  }
```

10.2.2.3.4 BnToBytes()

This function converts a BIG_NUM to a byte array. It converts the *bigNum* to a big-endian byte string and sets *size* to the normalized value. If *size* is an input 0, then the receiving buffer is guaranteed to be large enough for the result and the size will be set to the size required for *bigNum* (leading zeros suppressed).

The conversion for a little-endian machine simply requires that all significant bytes of the *bigNum* be reversed. For a big-endian machine, rather than unpack each word individually, the *bigNum* is converted to little-endian words, copied, and then converted back to big-endian.

```
100  LIB_EXPORT BOOL
101  BnToBytes(
102      bigConst             bn,
103      BYTE                *buffer,
104      NUMBYTES            *size           // This the number of bytes that are
105                                          // available in the buffer. The result
106                                          // should be this big.
107      )
108  {
109      crypt_uword_t        requiredSize;
110      BYTE                *pFrom;
111      BYTE                *pTo;
112      crypt_uword_t        count;
113  //
114      // validate inputs
115      pAssert(bn && buffer && size);
116
117      requiredSize = (BnSizeInBits(bn) + 7) / 8;
118      if(requiredSize == 0)
119      {
120          // If the input value is 0, return a byte of zero
121          *size = 1;
122          *buffer = 0;
123      }
124      else
125      {
126  #if BIG_ENDIAN_TPM
127          // Copy the constant input value into a modifiable value
128          BN_VAR(bnL, LARGEST_NUMBER_BITS * 2);
129          BnCopy(bnL, bn);
130          // byte swap the words in the local value to make them little-endian
131          for(count = 0; count < bnL->size; count++)
132              bnL->d[count] = SWAP_CRYPT_WORD(bnL->d[count]);
133          bn = (bigConst)bnL;
134  #endif
135          if(*size == 0)
136              *size = (NUMBYTES)requiredSize;
137          pAssert(requiredSize <= *size);
138          // Byte swap the number (not words but the whole value)
139          count = *size;
140          // Start from the least significant word and offset to the most significant
141          // byte which is in some high word
142          pFrom = (BYTE *)(&bn->d[0]) + requiredSize - 1;
143          pTo = buffer;
144
145          // If the number of output bytes is larger than the number bytes required
146          // for the input number, pad with zeros
147          for(count = *size; count > requiredSize; count--)
148              *pTo++ = 0;
```

```
149             // Move the most significant byte at the end of the BigNum to the next most
150             // significant byte position of the 2B and repeat for all significant bytes.
151             for(; requiredSize > 0; requiredSize--)
152                 *pTo++ = *pFrom--;
153         }
154         return TRUE;
155     }
```

10.2.2.3.5 BnTo2B()

Function to convert a BIG_NUM to TPM2B. The TPM2B size is set to the requested *size* which may require padding. If *size* is non-zero and less than required by the value in *bn* then an error is returned. If *size* is zero, then the TPM2B is assumed to be large enough for the data and a2b->size will be adjusted accordingly.

```
156     LIB_EXPORT BOOL
157     BnTo2B(
158         bigConst         bn,                  // IN:
159         TPM2B           *a2B,                 // OUT:
160         NUMBYTES         size                 // IN: the desired size
161         )
162     {
163         // Set the output size
164         if(bn && a2B)
165         {
166             a2B->size = size;
167             return BnToBytes(bn, a2B->buffer, &a2B->size);
168         }
169         return FALSE;
170     }
171     #if ALG_ECC
```

10.2.2.3.6 BnPointFrom2B()

Function to create a BIG_POINT structure from a 2B point. A point is going to be two ECC values in the same buffer. The values are going to be the size of the modulus. They are in modular form.

```
172     LIB_EXPORT bn_point_t   *
173     BnPointFrom2B(
174         bigPoint             ecP,          // OUT: the preallocated point structure
175         TPMS_ECC_POINT      *p             // IN: the number to convert
176         )
177     {
178         if(p == NULL)
179             return NULL;
180
181         if(NULL != ecP)
182         {
183             BnFrom2B(ecP->x, &p->x.b);
184             BnFrom2B(ecP->y, &p->y.b);
185             BnSetWord(ecP->z, 1);
186         }
187         return ecP;
188     }
```

10.2.2.3.7 BnPointTo2B()

This function converts a BIG_POINT into a TPMS_ECC_POINT. A TPMS_ECC_POINT contains two TPM2B_ECC_PARAMETER values. The maximum size of the parameters is dependent on the maximum

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

EC key size used in an implementation. The presumption is that the TPMS_ECC_POINT is large enough to hold 2 TPM2B values, each as large as a MAX_ECC_PARAMETER_BYTES

```
189   LIB_EXPORT BOOL
190   BnPointTo2B(
191       TPMS_ECC_POINT  *p,             // OUT: the converted 2B structure
192       bigPoint         ecP,           // IN: the values to be converted
193       bigCurve         E              // IN: curve descriptor for the point
194       )
195   {
196       UINT16           size;
197   //
198       pAssert(p && ecP && E);
199       pAssert(BnEqualWord(ecP->z, 1));
200       // BnMsb is the bit number of the MSB. This is one less than the number of bits
201       size = (UINT16)BITS_TO_BYTES(BnSizeInBits(CurveGetOrder(AccessCurveData(E))));
202       BnTo2B(ecP->x, &p->x.b, size);
203       BnTo2B(ecP->y, &p->y.b, size);
204       return TRUE;
205   }
206   #endif // ALG_ECC
```

10.2.3 BnMath.c

10.2.3.1 Introduction

The simulator code uses the canonical form whenever possible in order to make the code in Part 3 more accessible. The canonical data formats are simple and not well suited for complex big number computations. When operating on big numbers, the data format is changed for easier manipulation. The format is native words in little-endian format. As the magnitude of the number decreases, the length of the array containing the number decreases but the starting address doesn't change.

The functions in this file perform simple operations on these big numbers. Only the more complex operations are passed to the underlying support library. Although the support library would have most of these functions, the interface code to convert the format for the values is greater than the size of the code to implement the functions here. So, rather than incur the overhead of conversion, they are done here.

If an implementer would prefer, the underlying library can be used simply by making code substitutions here.

NOTE: There is an intention to continue to augment these functions so that there would be no need to use an external big number library.

Many of these functions have no error returns and will always return TRUE. This is to allow them to be used in **guarded** sequences. That is: OK = OK || BnSomething(s); where the BnSomething() function should not be called if OK isn't true.

10.2.3.2 Includes

```
1  #include "Tpm.h"
```

A constant value of zero as a stand in for NULL *bigNum* values

```
2  const bignum_t   BnConstZero = {1, 0, {0}};
3
4  //** Functions
5
6  //*** AddSame()
7  // Adds two values that are the same size. This function allows 'result' to be
8  // the same as either of the addends. This is a nice function to put into assembly
9  // because handling the carry for multi-precision stuff is not as easy in C
10 // (unless there is a REALLY smart compiler). It would be nice if there were idioms
11 // in a language that a compiler could recognize what is going on and optimize
12 // loops like this.
13 //  Return Type: int
14 //      0           no carry out
15 //      1           carry out
16 static BOOL
17 AddSame(
18     crypt_uword_t           *result,
19     const crypt_uword_t     *op1,
20     const crypt_uword_t     *op2,
21     int                      count
22     )
23 {
24     int         carry = 0;
25     int         i;
26
27     for(i = 0; i < count; i++)
28     {
29         crypt_uword_t        a = op1[i];
30         crypt_uword_t        sum = a + op2[i];
31         result[i] = sum + carry;
```

```
32            // generate a carry if the sum is less than either of the inputs
33            // propagate a carry if there was a carry and the sum + carry is zero
34            // do this using bit operations rather than logical operations so that
35            // the time is about the same.
36            //             propagate term      | generate term
37            carry = ((result[i] == 0) & carry) | (sum < a);
38        }
39        return carry;
40    }
```

10.2.3.2.1 CarryProp()

Propagate a carry

```
41    static int
42    CarryProp(
43        crypt_uword_t           *result,
44        const crypt_uword_t     *op,
45        int                      count,
46        int                      carry
47        )
48    {
49        for(; count; count--)
50            carry = ((*result++ = *op++ + carry) == 0) & carry;
51        return carry;
52    }
53    static void
54    CarryResolve(
55        bigNum          result,
56        int             stop,
57        int             carry
58        )
59    {
60        if(carry)
61        {
62            pAssert((unsigned)stop < result->allocated);
63            result->d[stop++] = 1;
64        }
65        BnSetTop(result, stop);
66    }
```

10.2.3.2.2 BnAdd()

This function adds two *bigNum* values. This function always returns TRUE.

```
67    LIB_EXPORT BOOL
68    BnAdd(
69        bigNum           result,
70        bigConst         op1,
71        bigConst         op2
72        )
73    {
74        crypt_uword_t    stop;
75        int              carry;
76        const bignum_t   *n1 = op1;
77        const bignum_t   *n2 = op2;
78
79    //
80        if(n2->size > n1->size)
81        {
82            n1 = op2;
83            n2 = op1;
84        }
```

```
85      pAssert(result->allocated >= n1->size);
86      stop = MIN(n1->size, n2->allocated);
87      carry = (int)AddSame(result->d, n1->d, n2->d, (int)stop);
88      if(n1->size > stop)
89          carry = CarryProp(&result->d[stop], &n1->d[stop], (int)(n1->size - stop),
carry);
90      CarryResolve(result, (int)n1->size, carry);
91      return TRUE;
92  }
```

10.2.3.2.3 BnAddWord()

This function adds a word value to a *bigNum*. This function always returns TRUE.

```
93  LIB_EXPORT BOOL
94  BnAddWord(
95      bigNum            result,
96      bigConst          op,
97      crypt_uword_t     word
98      )
99  {
100     int               carry;
101 //
102     carry = (result->d[0] = op->d[0] + word) < word;
103     carry = CarryProp(&result->d[1], &op->d[1], (int)(op->size - 1), carry);
104     CarryResolve(result, (int)op->size, carry);
105     return TRUE;
106 }
```

10.2.3.2.4 SubSame()

This function subtracts two values that have the same size.

```
107 static int
108 SubSame(
109     crypt_uword_t           *result,
110     const crypt_uword_t     *op1,
111     const crypt_uword_t     *op2,
112     int                      count
113     )
114 {
115     int                 borrow = 0;
116     int                 i;
117     for(i = 0; i < count; i++)
118     {
119         crypt_uword_t    a = op1[i];
120         crypt_uword_t    diff = a - op2[i];
121         result[i] = diff - borrow;
122         //       generate    |       propagate
123         borrow = (diff > a) | ((diff == 0) & borrow);
124     }
125     return borrow;
126 }
```

10.2.3.2.5 BorrowProp()

This propagates a borrow. If borrow is true when the end of the array is reached, then it means that op2 was larger than op1 and we don't handle that case so an assert is generated. This design choice was made because our only *bigNum* computations are on large positive numbers (primes) or on fields. Propagate a borrow.

 Copyright © TCG 2006-2020

```
127     static int
128     BorrowProp(
129         crypt_uword_t           *result,
130         const crypt_uword_t     *op,
131         int                      size,
132         int                      borrow
133         )
134     {
135         for(; size > 0; size--)
136             borrow = ((*result++ = *op++ - borrow) == MAX_CRYPT_UWORD) && borrow;
137         return borrow;
138     }
```

10.2.3.2.6 BnSub()

This function does subtraction of two *bigNum* values and returns result = op1 - op2 when op1 is greater than op2. If op2 is greater than op1, then a fault is generated. This function always returns TRUE.

```
139     LIB_EXPORT BOOL
140     BnSub(
141         bigNum            result,
142         bigConst          op1,
143         bigConst          op2
144         )
145     {
146         int              borrow;
147         int              stop = (int)MIN(op1->size, op2->allocated);
148     //
149         // Make sure that op2 is not obviously larger than op1
150         pAssert(op1->size >= op2->size);
151         borrow = SubSame(result->d, op1->d, op2->d, stop);
152         if(op1->size > (crypt_uword_t)stop)
153             borrow = BorrowProp(&result->d[stop], &op1->d[stop], (int)(op1->size - stop),
154                                 borrow);
155         pAssert(!borrow);
156         BnSetTop(result, op1->size);
157         return TRUE;
158     }
```

10.2.3.2.7 BnSubWord()

This function subtracts a word value from a *bigNum*. This function always returns TRUE.

```
159     LIB_EXPORT BOOL
160     BnSubWord(
161         bigNum            result,
162         bigConst          op,
163         crypt_uword_t     word
164         )
165     {
166         int              borrow;
167     //
168         pAssert(op->size > 1 || word <= op->d[0]);
169         borrow = word > op->d[0];
170         result->d[0] = op->d[0] - word;
171         borrow = BorrowProp(&result->d[1], &op->d[1], (int)(op->size - 1), borrow);
172         pAssert(!borrow);
173         BnSetTop(result, op->size);
174         return TRUE;
175     }
```

 Copyright © TCG 2006-2020

10.2.3.2.8 BnUnsignedCmp()

This function performs a comparison of op1 to op2. The compare is approximately constant time if the size of the values used in the compare is consistent across calls (from the same line in the calling code).

Return Value	Meaning
0	op1 is less than op2
0	op1 is equal to op2
0	op1 is greater than op2

```
176  LIB_EXPORT int
177  BnUnsignedCmp(
178      bigConst                 op1,
179      bigConst                 op2
180      )
181  {
182      int              retVal;
183      int              diff;
184      int              i;
185  //
186      pAssert((op1 != NULL) && (op2 != NULL));
187      retVal = (int)(op1->size - op2->size);
188      if(retVal == 0)
189      {
190          for(i = (int)(op1->size - 1); i >= 0; i--)
191          {
192              diff = (op1->d[i] < op2->d[i]) ? -1 : (op1->d[i] != op2->d[i]);
193              retVal = retVal == 0 ? diff : retVal;
194          }
195      }
196      else
197          retVal = (retVal < 0) ? -1 : 1;
198      return retVal;
199  }
```

10.2.3.2.9 BnUnsignedCmpWord()

Compare a *bigNum* to a crypt_uword_t.

Return Value	Meaning
-1	op1 is less that word
0	op1 is equal to word
1	op1 is greater than word

```
200  LIB_EXPORT int
201  BnUnsignedCmpWord(
202      bigConst              op1,
203      crypt_uword_t         word
204      )
205  {
206      if(op1->size > 1)
207          return 1;
208      else if(op1->size == 1)
209          return (op1->d[0] < word) ? -1 : (op1->d[0] > word);
210      else // op1 is zero
211          // equal if word is zero
212          return (word == 0) ? 0 : -1;
213  }
```

 Copyright © TCG 2006-2020

10.2.3.2.10 BnModWord()

This function does modular division of a big number when the modulus is a word value.

```
214 LIB_EXPORT crypt_word_t
215 BnModWord(
216     bigConst         numerator,
217     crypt_word_t     modulus
218     )
219 {
220     BN_MAX(remainder);
221     BN_VAR(mod, RADIX_BITS);
222 //
223     mod->d[0] = modulus;
224     mod->size = (modulus != 0);
225     BnDiv(NULL, remainder, numerator, mod);
226     return remainder->d[0];
227 }
```

10.2.3.2.11 Msb()

This function returns the bit number of the most significant bit of a crypt_uword_t. The number for the least significant bit of any *bigNum* value is 0. The maximum return value is RADIX_BITS - 1,

Return Value	Meaning
-1	the word was zero
n	the bit number of the most significant bit in the word

```
228 LIB_EXPORT int
229 Msb(
230     crypt_uword_t           word
231     )
232 {
233     int               retVal = -1;
234 //
235 #if RADIX_BITS == 64
236     if(word & 0xffffffff00000000) { retVal += 32; word >>= 32; }
237 #endif
238     if(word & 0xffff0000) { retVal += 16; word >>= 16; }
239     if(word & 0x0000ff00) { retVal += 8; word >>= 8; }
240     if(word & 0x000000f0) { retVal += 4; word >>= 4; }
241     if(word & 0x0000000c) { retVal += 2; word >>= 2; }
242     if(word & 0x00000002) { retVal += 1; word >>= 1; }
243     return retVal + (int)word;
244 }
```

10.2.3.2.12 BnMsb()

This function returns the number of the MSb of a *bigNum* value.

Return Value	Meaning
-1	the word was zero or *bn* was NULL
n	the bit number of the most significant bit in the word

```
245 LIB_EXPORT int
246 BnMsb(
247     bigConst              bn
248     )
```

 Copyright © TCG 2006-2020

```
249 {
250     // If the value is NULL, or the size is zero then treat as zero and return -1
251     if(bn != NULL && bn->size > 0)
252     {
253         int          retVal = Msb(bn->d[bn->size - 1]);
254         retVal += (int)(bn->size - 1) * RADIX_BITS;
255         return retVal;
256     }
257     else
258         return -1;
259 }
```

10.2.3.2.13 BnSizeInBits()

This function returns the number of bits required to hold a number. It is one greater than the Msb.

```
260 LIB_EXPORT unsigned
261 BnSizeInBits(
262     bigConst                 n
263     )
264 {
265     int     bits = BnMsb(n) + 1;
266 //
267     return bits < 0? 0 : (unsigned)bits;
268 }
```

10.2.3.2.14 BnSetWord()

Change the value of a bignum_t to a word value.

```
269 LIB_EXPORT bigNum
270 BnSetWord(
271     bigNum               n,
272     crypt_uword_t        w
273     )
274 {
275     if(n != NULL)
276     {
277         pAssert(n->allocated > 1);
278         n->d[0] = w;
279         BnSetTop(n, (w != 0) ? 1 : 0);
280     }
281     return n;
282 }
```

10.2.3.2.15 BnSetBit()

This function will SET a bit in a *bigNum*. Bit 0 is the least-significant bit in the 0th digit_t. The function always return TRUE

```
283 LIB_EXPORT BOOL
284 BnSetBit(
285     bigNum           bn,        // IN/OUT: big number to modify
286     unsigned int     bitNum     // IN: Bit number to SET
287     )
288 {
289     crypt_uword_t            offset = bitNum / RADIX_BITS;
290     pAssert(bn->allocated * RADIX_BITS >= bitNum);
291     // Grow the number if necessary to set the bit.
292     while(bn->size <= offset)
293         bn->d[bn->size++] = 0;
```

 Copyright © TCG 2006-2020

```
294       bn->d[offset] |= ((crypt_uword_t)1 << RADIX_MOD(bitNum));
295       return TRUE;
296   }
```

10.2.3.2.16 BnTestBit()

This function is used to check to see if a bit is SET in a bignum_t. The 0th bit is the LSb of d[0].

Return Value	Meaning
TRUE(1)	the bit is set
FALSE(0)	the bit is not set or the number is out of range

```
297   LIB_EXPORT BOOL
298   BnTestBit(
299       bigNum                  bn,         // IN: number to check
300       unsigned int            bitNum      // IN: bit to test
301       )
302   {
303       crypt_uword_t            offset = RADIX_DIV(bitNum);
304   //
305       if(bn->size > offset)
306           return ((bn->d[offset] & (((crypt_uword_t)1) << RADIX_MOD(bitNum))) != 0);
307       else
308           return FALSE;
309   }
```

10.2.3.2.17 BnMaskBits()

This function is used to mask off high order bits of a big number. The returned value will have no more than *maskBit* bits set.

NOTE: There is a requirement that unused words of a bignum_t are set to zero.

Return Value	Meaning
TRUE(1)	result masked
FALSE(0)	the input was not as large as the mask

```
310   LIB_EXPORT BOOL
311   BnMaskBits(
312       bigNum              bn,         // IN/OUT: number to mask
313       crypt_uword_t       maskBit     // IN: the bit number for the mask.
314       )
315   {
316       crypt_uword_t       finalSize;
317       BOOL                retVal;
318
319       finalSize = BITS_TO_CRYPT_WORDS(maskBit);
320       retVal = (finalSize <= bn->allocated);
321       if(retVal && (finalSize > 0))
322       {
323           crypt_uword_t    mask;
324           mask = ~((crypt_uword_t)0) >> RADIX_MOD(maskBit);
325           bn->d[finalSize - 1] &= mask;
326       }
327       BnSetTop(bn, finalSize);
328       return retVal;
329   }
```

10.2.3.2.18 BnShiftRight()

This function will shift a *bigNum* to the right by the *shiftAmount*. This function always returns TRUE.

```
330 LIB_EXPORT BOOL
331 BnShiftRight(
332     bigNum          result,
333     bigConst        toShift,
334     uint32_t        shiftAmount
335     )
336 {
337     uint32_t        offset = (shiftAmount >> RADIX_LOG2);
338     uint32_t        i;
339     uint32_t        shiftIn;
340     crypt_uword_t   finalSize;
341 //
342     shiftAmount = shiftAmount & RADIX_MASK;
343     shiftIn = RADIX_BITS - shiftAmount;
344
345     // The end size is toShift->size - offset less one additional
346     // word if the shiftAmount would make the upper word == 0
347     if(toShift->size > offset)
348     {
349         finalSize = toShift->size - offset;
350         finalSize -= (toShift->d[toShift->size - 1] >> shiftAmount) == 0 ? 1 : 0;
351     }
352     else
353         finalSize = 0;
354
355     pAssert(finalSize <= result->allocated);
356     if(finalSize != 0)
357     {
358         for(i = 0; i < finalSize; i++)
359         {
360             result->d[i] = (toShift->d[i + offset] >> shiftAmount)
361                 | (toShift->d[i + offset + 1] << shiftIn);
362         }
363         if(offset == 0)
364             result->d[i] = toShift->d[i] >> shiftAmount;
365     }
366     BnSetTop(result, finalSize);
367     return TRUE;
368 }
```

10.2.3.2.19 BnGetRandomBits()

This function gets random bits for use in various places. To make sure that the number is generated in a portable format, it is created as a TPM2B and then converted to the internal format.

One consequence of the generation scheme is that, if the number of bits requested is not a multiple of 8, then the high-order bits are set to zero. This would come into play when generating a 521-bit ECC key. A 66-byte (528-bit) value is generated an the high order 7 bits are masked off (CLEAR).

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
369 LIB_EXPORT BOOL
370 BnGetRandomBits(
371     bigNum          n,
372     size_t          bits,
```

 Copyright © TCG 2006-2020

```
373         RAND_STATE       *rand
374     )
375     {
376         // Since this could be used for ECC key generation using the extra bits method,
377         // make sure that the value is large enough
378         TPM2B_TYPE(LARGEST, LARGEST_NUMBER + 8);
379         TPM2B_LARGEST    large;
380     //
381         large.b.size = (UINT16)BITS_TO_BYTES(bits);
382         if(DRBG_Generate(rand, large.t.buffer, large.t.size) == large.t.size)
383         {
384             if(BnFrom2B(n, &large.b) != NULL)
385             {
386                 if(BnMaskBits(n, (crypt_uword_t)bits))
387                     return TRUE;
388             }
389         }
390         return FALSE;
391     }
```

10.2.3.2.20 BnGenerateRandomInRange()

This function is used to generate a random number r in the range 1 <= r < limit. The function gets a random number of bits that is the size of limit. There is some some probability that the returned number is going to be greater than or equal to the limit. If it is, try again. There is no more than 50% chance that the next number is also greater, so try again. We keep trying until we get a value that meets the criteria. Since limit is very often a number with a LOT of high order ones, this rarely would need a second try.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure (*limit* is too small)

```
392     LIB_EXPORT BOOL
393     BnGenerateRandomInRange(
394         bigNum           dest,
395         bigConst         limit,
396         RAND_STATE      *rand
397         )
398     {
399         size_t   bits = BnSizeInBits(limit);
400     //
401         if(bits < 2)
402         {
403             BnSetWord(dest, 0);
404             return FALSE;
405         }
406         else
407         {
408             while(BnGetRandomBits(dest, bits, rand)
409                   && (BnEqualZero(dest) || (BnUnsignedCmp(dest, limit) >= 0)));
410         }
411         return !g_inFailureMode;
412     }
```

10.2.4 BnMemory.c

10.2.4.1 Introduction

This file contains the memory setup functions used by the *bigNum* functions in CryptoEngine()

10.2.4.2 Includes

```
1   #include "Tpm.h"
```

10.2.4.3 Functions

10.2.4.3.1 BnSetTop()

This function is used when the size of a bignum_t is changed. It makes sure that the unused words are set to zero and that any significant words of zeros are eliminated from the used size indicator.

```
2   LIB_EXPORT bigNum
3   BnSetTop(
4       bigNum           bn,         // IN/OUT: number to clean
5       crypt_uword_t    top         // IN: the new top
6       )
7   {
8       if(bn != NULL)
9       {
10          pAssert(top <= bn->allocated);
11          // If forcing the size to be decreased, make sure that the words being
12          // discarded are being set to 0
13          while(bn->size > top)
14              bn->d[--bn->size] = 0;
15          bn->size = top;
16          // Now make sure that the words that are left are 'normalized' (no high-order
17          // words of zero.
18          while((bn->size > 0) && (bn->d[bn->size - 1] == 0))
19              bn->size -= 1;
20      }
21      return bn;
22  }
```

10.2.4.3.2 BnClearTop()

This function will make sure that all unused words are zero.

```
23  LIB_EXPORT bigNum
24  BnClearTop(
25      bigNum          bn
26      )
27  {
28      crypt_uword_t       i;
29  //
30      if(bn != NULL)
31      {
32          for(i = bn->size; i < bn->allocated; i++)
33              bn->d[i] = 0;
34          while((bn->size > 0) && (bn->d[bn->size] == 0))
35              bn->size -= 1;
36      }
37      return bn;
38  }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

10.2.4.3.3 BnInitializeWord()

This function is used to initialize an allocated *bigNum* with a word value. The *bigNum* does not have to be allocated with a single word.

```
39  LIB_EXPORT bigNum
40  BnInitializeWord(
41      bigNum          bn,         // IN:
42      crypt_uword_t   allocated,  // IN:
43      crypt_uword_t   word        // IN:
44      )
45  {
46      bn->allocated = allocated;
47      bn->size = (word != 0);
48      bn->d[0] = word;
49      while(allocated > 1)
50          bn->d[--allocated] = 0;
51      return bn;
52  }
```

10.2.4.3.4 BnInit()

This function initializes a stack allocated bignum_t. It initializes *allocated* and *size* and zeros the words of *d*.

```
53  LIB_EXPORT bigNum
54  BnInit(
55      bigNum              bn,
56      crypt_uword_t       allocated
57      )
58  {
59      if(bn != NULL)
60      {
61          bn->allocated = allocated;
62          bn->size = 0;
63          while(allocated != 0)
64              bn->d[--allocated] = 0;
65      }
66      return bn;
67  }
```

10.2.4.3.5 BnCopy()

Function to copy a bignum_t. If the output is NULL, then nothing happens. If the input is NULL, the output is set to zero.

```
68  LIB_EXPORT BOOL
69  BnCopy(
70      bigNum          out,
71      bigConst        in
72      )
73  {
74      if(in == out)
75          BnSetTop(out, BnGetSize(out));
76      else if(out != NULL)
77      {
78          if(in != NULL)
79          {
80              unsigned int        i;
81              pAssert(BnGetAllocated(out) >= BnGetSize(in));
82              for(i = 0; i < BnGetSize(in); i++)
83                  out->d[i] = in->d[i];
```

```
84              BnSetTop(out, BnGetSize(in));
85          }
86          else
87              BnSetTop(out, 0);
88      }
89      return TRUE;
90  }
91  #if ALG_ECC
```

10.2.4.3.6 BnPointCopy()

Function to copy a bn point.

```
92  LIB_EXPORT BOOL
93  BnPointCopy(
94      bigPoint                 pOut,
95      pointConst               pIn
96      )
97  {
98      return BnCopy(pOut->x, pIn->x)
99          && BnCopy(pOut->y, pIn->y)
100         && BnCopy(pOut->z, pIn->z);
101 }
```

10.2.4.3.7 BnInitializePoint()

This function is used to initialize a point structure with the addresses of the coordinates.

```
102 LIB_EXPORT bn_point_t *
103 BnInitializePoint(
104     bigPoint             p,     // OUT: structure to receive pointers
105     bigNum               x,     // IN: x coordinate
106     bigNum               y,     // IN: y coordinate
107     bigNum               z      // IN: x coordinate
108     )
109 {
110     p->x = x;
111     p->y = y;
112     p->z = z;
113     BnSetWord(z, 1);
114     return p;
115 }
116 #endif // ALG_ECC
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

10.2.5 CryptCmac.c

10.2.5.1 Introduction

This file contains the implementation of the message authentication codes based on a symmetric block cipher. These functions only use the single block encryption functions of the selected symmetric cryptographic library.

10.2.5.2 Includes, Defines, and Typedefs

```
1   #define _CRYPT_HASH_C_
2   #include "Tpm.h"
3   #include "CryptSym.h"
4   #if ALG_CMAC
```

10.2.5.3 Functions

10.2.5.3.1 CryptCmacStart()

This is the function to start the CMAC sequence operation. It initializes the dispatch functions for the data and end operations for CMAC and initializes the parameters that are used for the processing of data, including the key, key size and block cipher algorithm.

```
5   UINT16
6   CryptCmacStart(
7       SMAC_STATE          *state,
8       TPMU_PUBLIC_PARMS   *keyParms,
9       TPM_ALG_ID           macAlg,
10      TPM2B               *key
11  )
12  {
13      tpmCmacState_t      *cState = &state->state.cmac;
14      TPMT_SYM_DEF_OBJECT *def = &keyParms->symDetail.sym;
15  //
16      if(macAlg != TPM_ALG_CMAC)
17          return 0;
18      // set up the encryption algorithm and parameters
19      cState->symAlg = def->algorithm;
20      cState->keySizeBits = def->keyBits.sym;
21      cState->iv.t.size = CryptGetSymmetricBlockSize(def->algorithm,
22                                                     def->keyBits.sym);
23      MemoryCopy2B(&cState->symKey.b, key, sizeof(cState->symKey.t.buffer));
24
25      // Set up the dispatch methods for the CMAC
26      state->smacMethods.data = CryptCmacData;
27      state->smacMethods.end = CryptCmacEnd;
28      return cState->iv.t.size;
29  }
```

10.2.5.3.2 CryptCmacData()

This function is used to add data to the CMAC sequence computation. The function will XOR new data into the IV. If the buffer is full, and there is additional input data, the data is encrypted into the IV buffer, the new data is then XOR into the IV. When the data runs out, the function returns without encrypting even if the buffer is full. The last data block of a sequence will not be encrypted until the call to CryptCmacEnd(). This is to allow the proper subkey to be computed and applied before the last block is encrypted.

```
30  void
31  CryptCmacData(
32      SMAC_STATES          *state,
33      UINT32                size,
34      const BYTE           *buffer
35  )
36  {
37      tpmCmacState_t           *cmacState = &state->cmac;
38      TPM_ALG_ID                algorithm = cmacState->symAlg;
39      BYTE                     *key = cmacState->symKey.t.buffer;
40      UINT16                    keySizeInBits = cmacState->keySizeBits;
41      tpmCryptKeySchedule_t     keySchedule;
42      TpmCryptSetSymKeyCall_t   encrypt;
43  //
44      SELECT(ENCRYPT);
45      while(size > 0)
46      {
47          if(cmacState->bcount == cmacState->iv.t.size)
48          {
49              ENCRYPT(&keySchedule, cmacState->iv.t.buffer, cmacState->iv.t.buffer);
50              cmacState->bcount = 0;
51          }
52          for(;(size > 0) && (cmacState->bcount < cmacState->iv.t.size);
53              size--, cmacState->bcount++)
54          {
55              cmacState->iv.t.buffer[cmacState->bcount] ^= *buffer++;
56          }
57      }
58  }
```

10.2.5.3.3 CryptCmacEnd()

This is the completion function for the CMAC. It does padding, if needed, and selects the subkey to be applied before the last block is encrypted.

```
59  UINT16
60  CryptCmacEnd(
61      SMAC_STATES              *state,
62      UINT32                    outSize,
63      BYTE                     *outBuffer
64  )
65  {
66      tpmCmacState_t           *cState = &state->cmac;
67      // Need to set algorithm, key, and keySizeInBits in the local context so that
68      // the SELECT and ENCRYPT macros will work here
69      TPM_ALG_ID                algorithm = cState->symAlg;
70      BYTE                     *key = cState->symKey.t.buffer;
71      UINT16                    keySizeInBits = cState->keySizeBits;
72      tpmCryptKeySchedule_t     keySchedule;
73      TpmCryptSetSymKeyCall_t   encrypt;
74      TPM2B_IV                  subkey = {{0, {0}}};
75      BOOL                      xorVal;
76      UINT16                    i;
77
78      subkey.t.size = cState->iv.t.size;
79      // Encrypt a block of zero
80      SELECT(ENCRYPT);
81      ENCRYPT(&keySchedule, subkey.t.buffer, subkey.t.buffer);
82
83      // shift left by 1 and XOR with 0x0...87 if the MSb was 0
84      xorVal = ((subkey.t.buffer[0] & 0x80) == 0) ? 0 : 0x87;
85      ShiftLeft(&subkey.b);
86      subkey.t.buffer[subkey.t.size - 1] ^= xorVal;
87      // this is a sanity check to make sure that the algorithm is working properly.
```

10.2.6 CryptUtil.c

10.2.6.1 Introduction

This module contains the interfaces to the CryptoEngine() and provides miscellaneous cryptographic functions in support of the TPM.

10.2.6.2 Includes

```
1     #include "Tpm.h"
```

10.2.6.3 Hash/HMAC Functions

10.2.6.3.1 CryptHmacSign()

Sign a digest using an HMAC key. This an HMAC of a digest, not an HMAC of a message.

Error Returns	Meaning
TPM_RC_HASH	not a valid hash

```
2     static TPM_RC
3     CryptHmacSign(
4         TPMT_SIGNATURE       *signature,      // OUT: signature
5         OBJECT               *signKey,        // IN: HMAC key sign the hash
6         TPM2B_DIGEST         *hashData        // IN: hash to be signed
7         )
8     {
9         HMAC_STATE       hmacState;
10        UINT32           digestSize;
11
12        digestSize = CryptHmacStart2B(&hmacState, signature->signature.any.hashAlg,
13                                      &signKey->sensitive.sensitive.bits.b);
14        CryptDigestUpdate2B(&hmacState.hashState, &hashData->b);
15        CryptHmacEnd(&hmacState, digestSize,
16                     (BYTE *)&signature->signature.hmac.digest);
17        return TPM_RC_SUCCESS;
18    }
```

10.2.6.3.2 CryptHMACVerifySignature()

This function will verify a signature signed by a HMAC key. Note that a caller needs to prepare *signature* with the signature algorithm (TPM_ALG_HMAC) and the hash algorithm to use. This function then builds a signature of that type.

Error Returns	Meaning
TPM_RC_SCHEME	not the proper scheme for this key type
TPM_RC_SIGNATURE	if invalid input or signature is not genuine

```
19    static TPM_RC
20    CryptHMACVerifySignature(
21        OBJECT               *signKey,        // IN: HMAC key signed the hash
22        TPM2B_DIGEST         *hashData,       // IN: digest being verified
23        TPMT_SIGNATURE       *signature       // IN: signature to be verified
24        )
25    {
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
26      TPMT_SIGNATURE            test;
27      TPMT_KEYEDHASH_SCHEME    *keyScheme =
28                              &signKey->publicArea.parameters.keyedHashDetail.scheme;
29  //
30      if((signature->sigAlg != ALG_HMAC_VALUE)
31         || (signature->signature.hmac.hashAlg == ALG_NULL_VALUE))
32          return TPM_RC_SCHEME;
33      // This check is not really needed for verification purposes. However, it does
34      // prevent someone from trying to validate a signature using a weaker hash
35      // algorithm than otherwise allowed by the key. That is, a key with a scheme
36      // other than TMP_ALG_NULL can only be used to validate signatures that have
37      // a matching scheme.
38      if((keyScheme->scheme != ALG_NULL_VALUE)
39         && ((keyScheme->scheme != signature->sigAlg)
40             || (keyScheme->details.hmac.hashAlg
41                 != signature->signature.any.hashAlg)))
42          return TPM_RC_SIGNATURE;
43      test.sigAlg = signature->sigAlg;
44      test.signature.hmac.hashAlg = signature->signature.hmac.hashAlg;
45
46      CryptHmacSign(&test, signKey, hashData);
47
48      // Compare digest
49      if(!MemoryEqual(&test.signature.hmac.digest,
50                      &signature->signature.hmac.digest,
51                      CryptHashGetDigestSize(signature->signature.any.hashAlg)))
52          return TPM_RC_SIGNATURE;
53
54      return TPM_RC_SUCCESS;
55  }
```

10.2.6.3.3 CryptGenerateKeyedHash()

This function creates a *keyedHash* object.

Error Returns	Meaning
TPM_RC_NO_RESULT	cannot get values from random number generator
TPM_RC_SIZE	sensitive data size is larger than allowed for the scheme

```
56  static TPM_RC
57  CryptGenerateKeyedHash(
58      TPMT_PUBLIC              *publicArea,        // IN/OUT: the public area template
59                                                   //     for the new key.
60      TPMT_SENSITIVE           *sensitive,         // OUT: sensitive area
61      TPMS_SENSITIVE_CREATE    *sensitiveCreate,   // IN: sensitive creation data
62      RAND_STATE               *rand               // IN: "entropy" source
63      )
64  {
65      TPMT_KEYEDHASH_SCHEME    *scheme;
66      TPM_ALG_ID                hashAlg;
67      UINT16                    digestSize;
68
69      scheme = &publicArea->parameters.keyedHashDetail.scheme;
70
71      if(publicArea->type != ALG_KEYEDHASH_VALUE)
72          return TPM_RC_FAILURE;
73
74      // Pick the limiting hash algorithm
75      if(scheme->scheme == ALG_NULL_VALUE)
76          hashAlg = publicArea->nameAlg;
77      else if(scheme->scheme == ALG_XOR_VALUE)
78          hashAlg = scheme->details.xor.hashAlg;
```

```
79         else
80             hashAlg = scheme->details.hmac.hashAlg;
81         digestSize = CryptHashGetDigestSize(hashAlg);
82
83         // if this is a signing or a decryption key, then the limit
84         // for the data size is the block size of the hash. This limit
85         // is set because larger values have lower entropy because of the
86         // HMAC function. The lower limit is 1/2 the size of the digest
87         //
88         //If the user provided the key, check that it is a proper size
89         if(sensitiveCreate->data.t.size != 0)
90         {
91             if(IS_ATTRIBUTE(publicArea->objectAttributes, TPMA_OBJECT, decrypt)
92                || IS_ATTRIBUTE(publicArea->objectAttributes, TPMA_OBJECT, sign))
93             {
94                 if(sensitiveCreate->data.t.size > CryptHashGetBlockSize(hashAlg))
95                     return TPM_RC_SIZE;
96     #if 0   // May make this a FIPS-mode requirement
97                 if(sensitiveCreate->data.t.size < (digestSize / 2))
98                     return TPM_RC_SIZE;
99     #endif
100            }
101            // If this is a data blob, then anything that will get past the unmarshaling
102            // is OK
103            MemoryCopy2B(&sensitive->sensitive.bits.b, &sensitiveCreate->data.b,
104                         sizeof(sensitive->sensitive.bits.t.buffer));
105        }
106        else
107        {
108            // The TPM is going to generate the data so set the size to be the
109            // size of the digest of the algorithm
110            sensitive->sensitive.bits.t.size =
111                DRBG_Generate(rand, sensitive->sensitive.bits.t.buffer, digestSize);
112            if(sensitive->sensitive.bits.t.size == 0)
113                return (g_inFailureMode) ? TPM_RC_FAILURE : TPM_RC_NO_RESULT;
114        }
115        return TPM_RC_SUCCESS;
116    }
```

10.2.6.3.4 CryptIsSchemeAnonymous()

This function is used to test a scheme to see if it is an anonymous scheme The only anonymous scheme is ECDAA. ECDAA can be used to do things like U-Prove.

```
117    BOOL
118    CryptIsSchemeAnonymous(
119        TPM_ALG_ID          scheme          // IN: the scheme algorithm to test
120        )
121    {
122        return scheme == ALG_ECDAA_VALUE;
123    }
```

10.2.6.4 Symmetric Functions

10.2.6.4.1 ParmDecryptSym()

This function performs parameter decryption using symmetric block cipher.

```
124    void
125    ParmDecryptSym(
126        TPM_ALG_ID          symAlg,         // IN: the symmetric algorithm
127        TPM_ALG_ID          hash,           // IN: hash algorithm for KDFa
```

```
128         UINT16             keySizeInBits, // IN: the key size in bits
129         TPM2B             *key,           // IN: KDF HMAC key
130         TPM2B             *nonceCaller,   // IN: nonce caller
131         TPM2B             *nonceTpm,      // IN: nonce TPM
132         UINT32             dataSize,      // IN: size of parameter buffer
133         BYTE              *data           // OUT: buffer to be decrypted
134         )
135     {
136         // KDF output buffer
137         // It contains parameters for the CFB encryption
138         // From MSB to LSB, they are the key and iv
139         BYTE               symParmString[MAX_SYM_KEY_BYTES + MAX_SYM_BLOCK_SIZE];
140         // Symmetric key size in byte
141         UINT16             keySize = (keySizeInBits + 7) / 8;
142         TPM2B_IV           iv;
143
144         iv.t.size = CryptGetSymmetricBlockSize(symAlg, keySizeInBits);
145         // If there is decryption to do...
146         if(iv.t.size > 0)
147         {
148             // Generate key and iv
149             CryptKDFa(hash, key, CFB_KEY, nonceCaller, nonceTpm,
150                       keySizeInBits + (iv.t.size * 8), symParmString, NULL, FALSE);
151             MemoryCopy(iv.t.buffer, &symParmString[keySize], iv.t.size);
152
153             CryptSymmetricDecrypt(data, symAlg, keySizeInBits, symParmString,
154                                   &iv, ALG_CFB_VALUE, dataSize, data);
155         }
156         return;
157     }
```

10.2.6.4.2 ParmEncryptSym()

This function performs parameter encryption using symmetric block cipher.

```
158     void
159     ParmEncryptSym(
160         TPM_ALG_ID         symAlg,        // IN: symmetric algorithm
161         TPM_ALG_ID         hash,          // IN: hash algorithm for KDFa
162         UINT16             keySizeInBits, // IN: symmetric key size in bits
163         TPM2B             *key,           // IN: KDF HMAC key
164         TPM2B             *nonceCaller,   // IN: nonce caller
165         TPM2B             *nonceTpm,      // IN: nonce TPM
166         UINT32             dataSize,      // IN: size of parameter buffer
167         BYTE              *data           // OUT: buffer to be encrypted
168         )
169     {
170         // KDF output buffer
171         // It contains parameters for the CFB encryption
172         BYTE               symParmString[MAX_SYM_KEY_BYTES + MAX_SYM_BLOCK_SIZE];
173
174         // Symmetric key size in bytes
175         UINT16             keySize = (keySizeInBits + 7) / 8;
176
177         TPM2B_IV           iv;
178
179         iv.t.size = CryptGetSymmetricBlockSize(symAlg, keySizeInBits);
180         // See if there is any encryption to do
181         if(iv.t.size > 0)
182         {
183             // Generate key and iv
184             CryptKDFa(hash, key, CFB_KEY, nonceTpm, nonceCaller,
185                       keySizeInBits + (iv.t.size * 8), symParmString, NULL, FALSE);
186             MemoryCopy(iv.t.buffer, &symParmString[keySize], iv.t.size);
```

```
187
188             CryptSymmetricEncrypt(data, symAlg, keySizeInBits, symParmString, &iv,
189                                   ALG_CFB_VALUE, dataSize, data);
190         }
191         return;
192     }
```

10.2.6.4.3 CryptGenerateKeySymmetric()

This function generates a symmetric cipher key. The derivation process is determined by the type of the provided *rand*

Error Returns	Meaning
TPM_RC_NO_RESULT	cannot get a random value
TPM_RC_KEY_SIZE	key size in the public area does not match the size in the sensitive creation area
TPM_RC_KEY	provided key value is not allowed

```
193 static TPM_RC
194 CryptGenerateKeySymmetric(
195     TPMT_PUBLIC             *publicArea,        // IN/OUT: The public area template
196                                                 //     for the new key.
197     TPMT_SENSITIVE          *sensitive,         // OUT: sensitive area
198     TPMS_SENSITIVE_CREATE   *sensitiveCreate,   // IN: sensitive creation data
199     RAND_STATE              *rand               // IN: the "entropy" source for
200     )
201 {
202     UINT16           keyBits = publicArea->parameters.symDetail.sym.keyBits.sym;

234     }
235     return result;
236 }
```

10.2.6.4.4 CryptXORObfuscation()

This function implements XOR obfuscation. It should not be called if the hash algorithm is not implemented. The only return value from this function is TPM_RC_SUCCESS.

```
237  void
238  CryptXORObfuscation(
239      TPM_ALG_ID        hash,           // IN: hash algorithm for KDF
240      TPM2B            *key,            // IN: KDF key
241      TPM2B            *contextU,       // IN: contextU
242      TPM2B            *contextV,       // IN: contextV
243      UINT32            dataSize,       // IN: size of data buffer
244      BYTE             *data            // IN/OUT: data to be XORed in place
245      )
246  {
247      BYTE              mask[MAX_DIGEST_SIZE]; // Allocate a digest sized buffer
248      BYTE             *pm;
249      UINT32            i;
250      UINT32            counter = 0;
251      UINT16            hLen = CryptHashGetDigestSize(hash);
252      UINT32            requestSize = dataSize * 8;
253      INT32             remainBytes = (INT32)dataSize;
254
255      pAssert((key != NULL) && (data != NULL) && (hLen != 0));
256
257      // Call KDFa to generate XOR mask
258      for(; remainBytes > 0; remainBytes -= hLen)
259      {
260          // Make a call to KDFa to get next iteration
261          CryptKDFa(hash, key, XOR_KEY, contextU, contextV,
262                    requestSize, mask, &counter, TRUE);
263
264      // XOR next piece of the data
265          pm = mask;
266          for(i = hLen < remainBytes ? hLen : remainBytes; i > 0; i--)
267              *data++ ^= *pm++;
268      }
269      return;
270  }
```

10.2.6.5 Initialization and shut down

10.2.6.5.1 CryptInit()

This function is called when the TPM receives a _TPM_Init() indication.

NOTE: The hash algorithms do not have to be tested, they just need to be available. They have to be tested before the TPM can accept HMAC authorization or return any result that relies on a hash algorithm.

Return Value	Meaning
TRUE(1)	initializations succeeded
FALSE(0)	initialization failed and caller should place the TPM into Failure Mode

```
271  BOOL
272  CryptInit(
273      void
274      )
275  {
276      BOOL          ok;
277      // Initialize the vector of implemented algorithms
```

 Copyright © TCG 2006-2020

```
278     AlgorithmGetImplementedVector(&g_implementedAlgorithms);
279
280     // Indicate that all test are necessary
281     CryptInitializeToTest();
282
283     // Do any library initializations that are necessary. If any fails,
284     // the caller should go into failure mode;
285     ok = SupportLibInit();
286     ok = ok && CryptSymInit();
287     ok = ok && CryptRandInit();
288     ok = ok && CryptHashInit();
289 #if ALG_RSA
290     ok = ok && CryptRsaInit();
291 #endif // ALG_RSA
292 #if ALG_ECC
293     ok = ok && CryptEccInit();
294 #endif // ALG_ECC
295     return ok;
296 }
```

10.2.6.5.2 CryptStartup()

This function is called by TPM2_Startup() to initialize the functions in this cryptographic library and in the provided CryptoLibrary(). This function and CryptUtilInit() are both provided so that the implementation may move the initialization around to get the best interaction.

Return Value	Meaning
TRUE(1)	startup succeeded
FALSE(0)	startup failed and caller should place the TPM into Failure Mode

```
297 BOOL
298 CryptStartup(
299     STARTUP_TYPE     type            // IN: the startup type
300     )
301 {
302     BOOL            OK;
303     NOT_REFERENCED(type);
304
305     OK = CryptSymStartup() && CryptRandStartup() && CryptHashStartup()
306 #if ALG_RSA
307         &&  CryptRsaStartup()
308 #endif // ALG_RSA
309 #if ALG_ECC
310         &&  CryptEccStartup()
311 #endif // ALG_ECC
312         ;
313 #if ALG_ECC
314     // Don't directly check for SU_RESET because that is the default
315     if(OK && (type != SU_RESTART) && (type != SU_RESUME))
316     {
317     // If the shutdown was orderly, then the values recovered from NV will
318     // be OK to use.
319         // Get a new  random commit nonce
320         gr.commitNonce.t.size = sizeof(gr.commitNonce.t.buffer);
321         CryptRandomGenerate(gr.commitNonce.t.size, gr.commitNonce.t.buffer);
322         // Reset the counter and commit array
323         gr.commitCounter = 0;
324         MemorySet(gr.commitArray, 0, sizeof(gr.commitArray));
325     }
326 #endif // ALG_ECC
327     return OK;
328 }
```

10.2.6.6 Algorithm-Independent Functions

10.2.6.6.1 Introduction

These functions are used generically when a function of a general type (e.g., symmetric encryption) is required. The functions will modify the parameters as required to interface to the indicated algorithms.

10.2.6.6.2 CryptIsAsymAlgorithm()

This function indicates if an algorithm is an asymmetric algorithm.

Return Value	Meaning
TRUE(1)	if it is an asymmetric algorithm
FALSE(0)	if it is not an asymmetric algorithm

```
329  BOOL
330  CryptIsAsymAlgorithm(
331      TPM_ALG_ID       algID          // IN: algorithm ID
332      )
333  {
334      switch(algID)
335      {
336  #if ALG_RSA
337          case ALG_RSA_VALUE:
338  #endif
339  #if ALG_ECC
340          case ALG_ECC_VALUE:
341  #endif
342              return TRUE;
343              break;
344          default:
345              break;
346      }
347      return FALSE;
348  }
```

10.2.6.6.3 CryptSecretEncrypt()

This function creates a secret value and its associated secret structure using an asymmetric algorithm.

This function is used by TPM2_Rewrap() TPM2_MakeCredential(), and TPM2_Duplicate().

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*keyHandle* does not reference a valid decryption key
TPM_RC_KEY	invalid ECC key (public point is not on the curve)
TPM_RC_SCHEME	RSA key with an unsupported padding scheme
TPM_RC_VALUE	numeric value of the data to be decrypted is greater than the RSA key modulus

```
349  TPM_RC
350  CryptSecretEncrypt(
351      OBJECT                  *encryptKey,     // IN: encryption key object
352      const TPM2B             *label,          // IN: a null-terminated string as L
353      TPM2B_DATA              *data,           // OUT: secret value
354      TPM2B_ENCRYPTED_SECRET  *secret          // OUT: secret structure
355      )
```

452 }
```

10.2.6.6.4 CryptSecretDecrypt()

Decrypt a secret value by asymmetric (or symmetric) algorithm This function is used for ActivateCredential() and Import for asymmetric decryption, and StartAuthSession() for both asymmetric and symmetric decryption process

Error Returns	Meaning
TPM_RC_ATTRIBUTES	RSA key is not a decryption key
TPM_RC_BINDING	Invalid RSA key (public and private parts are not cryptographically bound.
TPM_RC_ECC_POINT	ECC point in the secret is not on the curve
TPM_RC_INSUFFICIENT	failed to retrieve ECC point from the secret
TPM_RC_NO_RESULT	multiplication resulted in ECC point at infinity
TPM_RC_SIZE	data to decrypt is not of the same size as RSA key
TPM_RC_VALUE	For RSA key, numeric value of the encrypted data is greater than the modulus, or the recovered data is larger than the output buffer. For *keyedHash* or symmetric key, the secret is larger than the size of the digest produced by the name algorithm.
TPM_RC_FAILURE	internal error

```
453 TPM_RC

777         }
778         return;
779     }
```

10.2.6.6.8 CryptCreateObject()

This function creates an object. For an asymmetric key, it will create a key pair and, for a parent key, a seed value for child protections.

For an symmetric object, (TPM_ALG_SYMCIPHER or TPM_ALG_KEYEDHASH), it will create a secret key if the caller did not provide one. It will create a random secret seed value that is hashed with the secret value to create the public unique value.

publicArea, *sensitive*, and *sensitiveCreate* are the only required parameters and are the only ones that are used by TPM2_Create(). The other parameters are optional and are used when the generated Object needs to be deterministic. This is the case for both Primary Objects and Derived Objects.

When a seed value is provided, a RAND_STATE will be populated and used for all operations in the object generation that require a random number. In the simplest case, TPM2_CreatePrimary() will use *seed*, *label* and *context* with context being the hash of the template. If the Primary Object is in the Endorsement hierarchy, it will also populate *proof* with *ehProof*.

For derived keys, *seed* will be the secret value from the parent, *label* and *context* will be set according to the parameters of TPM2_CreateLoaded() and *hashAlg* will be set which causes the RAND_STATE to be a KDF generator.

Error Returns	Meaning
TPM_RC_KEY	a provided key is not an allowed value
TPM_RC_KEY_SIZE	key size in the public area does not match the size in the sensitive creation area for a symmetric key
TPM_RC_NO_RESULT	unable to get random values (only in derivation)
TPM_RC_RANGE	for an RSA key, the exponent is not supported
TPM_RC_SIZE	sensitive data size is larger than allowed for the scheme for a keyed hash object
TPM_RC_VALUE	exponent is not prime or could not find a prime using the provided parameters for an RSA key; unsupported name algorithm for an ECC key

```

1051 }
```

10.2.6.6.13 CryptSelectSignScheme()

This function is used by the attestation and signing commands. It implements the rules for selecting the signature scheme to use in signing. This function requires that the signing key either be TPM_RH_NULL or be loaded.

If a default scheme is defined in object, the default scheme should be chosen, otherwise, the input scheme should be chosen. In the case that both object and input scheme has a non-NULL scheme algorithm, if the schemes are compatible, the input scheme will be chosen.

This function should not be called if '*signObject->publicArea*.type' == ALG_SYMCIPHER.

Return Value	Meaning
TRUE(1)	scheme selected
FALSE(0)	both *scheme* and key's default scheme are empty; or *scheme* is empty while key's default scheme requires explicit input scheme (split signing); or non-empty default key scheme differs from *scheme*

```
1052 BOOL
1053 CryptSelectSignScheme(
1054     OBJECT              *signObject,    // IN: signing key
1055     TPMT_SIG_SCHEME     *scheme         // IN/OUT: signing scheme
1056     )
1057 {
1058     TPMT_SIG_SCHEME     *objectScheme;
1059     TPMT_PUBLIC         *publicArea;
1060     BOOL                 OK;
1061
1062     // If the signHandle is TPM_RH_NULL, then the NULL scheme is used, regardless
1063     // of the setting of scheme
1064     if(signObject == NULL)
```

1123        return OK;
1124    }
```

10.2.6.6.14 CryptSign()

Sign a digest with asymmetric key or HMAC. This function is called by attestation commands and the generic TPM2_Sign() command. This function checks the key scheme and digest size. It does not check if the sign operation is allowed for restricted key. It should be checked before the function is called. The function will assert if the key is not a signing key.

Error Returns	Meaning
TPM_RC_SCHEME	*signScheme* is not compatible with the signing key type
TPM_RC_VALUE	*digest* value is greater than the modulus of *signHandle* or size of *hashData* does not match hash algorithm in*signScheme* (for an RSA key); invalid commit status or failed to generate r value (for an ECC key)

```
1125   TPM_RC
1126   CryptSign(
1127       OBJECT              *signKey,       // IN: signing key
1128       TPMT_SIG_SCHEME     *signScheme,    // IN: sign scheme.
1129       TPM2B_DIGEST        *digest,        // IN: The digest being signed
1130       TPMT_SIGNATURE      *signature      // OUT: signature
1131       )
1132   {
1133       TPM_RC               result = TPM_RC_SCHEME;
1134
1135       // Initialize signature scheme
1136       signature->sigAlg = signScheme->scheme;
1137
1138       // If the signature algorithm is TPM_ALG_NULL or the signing key is NULL,
1139       // then we are done
1140       if((signature->sigAlg == ALG_NULL_VALUE) || (signKey == NULL))
1141           return TPM_RC_SUCCESS;
1142
1143       // Initialize signature hash
1144       // Note: need to do the check for TPM_ALG_NULL first because the null scheme
1145       // doesn't have a hashAlg member.
1146       signature->signature.any.hashAlg = signScheme->details.any.hashAlg;
1147
1148       // perform sign operation based on different key type
1149       switch(signKey->publicArea.type)
1150       {

10.2.6.6.15 CryptValidateSignature()

This function is used to verify a signature. It is called by TPM2_VerifySignature() and TPM2_PolicySigned().

Since this operation only requires use of a public key, no consistency checks are necessary for the key to signature type because a caller can load any public key that they like with any scheme that they like. This routine simply makes sure that the signature is correct, whatever the type.

Error Returns	Meaning
TPM_RC_SIGNATURE	the signature is not genuine
TPM_RC_SCHEME	the scheme is not supported
TPM_RC_HANDLE	an HMAC key was selected but the private part of the key is not loaded

```
1174 TPM_RC
1175 CryptValidateSignature(
1176     TPMI_DH_OBJECT   keyHandle,     // IN: The handle of sign key
1177     TPM2B_DIGEST    *digest,        // IN: The digest being validated
1178     TPMT_SIGNATURE  *signature      // IN: signature
1179     )
1180 {
1181     // NOTE: HandleToObject will either return a pointer to a loaded object or
1182     // will assert. It will never return a non-valid value. This makes it save
1183     // to initialize 'publicArea' with the return value from HandleToObject()
1184     // without checking it first.
1185     OBJECT              *signObject = HandleToObject(keyHandle);
1186     TPMT_PUBLIC         *publicArea = &signObject->publicArea;
1187     TPM_RC               result = TPM_RC_SCHEME;
1188
1189     // The input unmarshaling should prevent any input signature from being
1190     // a NULL signature, but just in case
1191     if(signature->sigAlg == ALG_NULL_VALUE)
1192         return TPM_RC_SIGNATURE;
1193
1194     switch(publicArea->type)
1195     {
1196 #if ALG_RSA
1197         case ALG_RSA_VALUE:
1198         {
1199     //
1200             // Call RSA code to verify signature
1201             result = CryptRsaValidateSignature(signature, signObject, digest);
1202             break;
1203         }
1204 #endif // ALG_RSA
1205
1206 #if ALG_ECC
1207         case ALG_ECC_VALUE:
1208             result = CryptEccValidateSignature(signature, signObject, digest);
1209             break;
1210 #endif // ALG_ECC
1211
1212         case ALG_KEYEDHASH_VALUE:
1213             if(signObject->attributes.publicOnly)

```
1221        return result;
1222    }
```

10.2.6.6.16 CryptGetTestResult

This function returns the results of a self-test function.

NOTE: the behavior in this function is NOT the correct behavior for a real TPM implementation. An artificial behavior is placed here due to the limitation of a software simulation environment. For the correct behavior, consult the part 3 specification for TPM2_GetTestResult().

```
1223    TPM_RC
1224    CryptGetTestResult(
1225        TPM2B_MAX_BUFFER    *outData        // OUT: test result data
1226        )
1227    {
1228        outData->t.size = 0;
1229        return TPM_RC_SUCCESS;
1230    }
```

10.2.6.6.17 CryptValidateKeys()

This function is used to verify that the key material of and object is valid. For a *publicOnly* object, the key is verified for size and, if it is an ECC key, it is verified to be on the specified curve. For a key with a sensitive area, the binding between the public and private parts of the key are verified. If the *nameAlg* of the key is TPM_ALG_NULL, then the size of the sensitive area is verified but the public portion is not verified, unless the key is an RSA key. For an RSA key, the reason for loading the sensitive area is to use it. The only way to use a private RSA key is to compute the private exponent. To compute the private exponent, the public modulus is used.

Error Returns	Meaning
TPM_RC_BINDING	the public and private parts are not cryptographically bound
TPM_RC_HASH	cannot have a *publicOnly* key with *nameAlg* of TPM_ALG_NULL
TPM_RC_KEY	the public unique is not valid
TPM_RC_KEY_SIZE	the private area key is not valid
TPM_RC_TYPE	the types of the sensitive and private parts do not match

```
1231    TPM_RC
1232    CryptValidateKeys(
1233        TPMT_PUBLIC      *publicArea,
1234        TPMT_SENSITIVE   *sensitive,
1235        TPM_RC            blamePublic,
1236        TPM_RC            blameSensitive
1237        )
1238    {
1239        TPM_RC                result;

1465            return TPM_RCS_SCHEME;
1466        return TPM_RC_SUCCESS;
1467    }
```

10.2.6.6.19 CryptMacIsValidForKey()

Check to see if the key type is compatible with the mac type

```
1468    BOOL
1469    CryptMacIsValidForKey(
1470        TPM_ALG_ID          keyType,
1471        TPM_ALG_ID          macAlg,
1472        BOOL                flag
1473    )
1474    {
1475        switch(keyType)
1476        {
1477            case ALG_KEYEDHASH_VALUE:
1478                return CryptHashIsValidAlg(macAlg, flag);
1479                break;
1480            case ALG_SYMCIPHER_VALUE:
1481                return CryptSmacIsValidAlg(macAlg, flag);
1482                break;
1483            default:
1484                break;
1485        }
1486        return FALSE;
1487    }
```

10.2.6.6.20 CryptSmacIsValidAlg()

This function is used to test if an algorithm is a supported SMAC algorithm. It needs to be updated as new algorithms are added.

```
1488 BOOL
1489 CryptSmacIsValidAlg(
1490     TPM_ALG_ID      alg,
1491     BOOL            FLAG        // IN: Indicates if TPM_ALG_NULL is valid
1492 )
1493 {
1494     switch (alg)
1495     {
1496 #if ALG_CMAC
1497         case ALG_CMAC_VALUE:
1498             return TRUE;
1499             break;
1500 #endif
1501         case ALG_NULL_VALUE:
1502             return FLAG;
1503             break;
1504         default:
1505             return FALSE;
1506     }
1507 }
```

10.2.6.6.21 CryptSymModeIsValid()

Function checks to see if an algorithm ID is a valid, symmetric block cipher mode for the TPM. If *flag* is SET, them TPM_ALG_NULL is a valid mode. not include the modes used for SMAC

```
1508 BOOL
1509 CryptSymModeIsValid(
1510     TPM_ALG_ID          mode,
1511     BOOL                flag
1512 )
1513 {
1514     switch(mode)
1515     {
1516 #if ALG_CTR
1517         case ALG_CTR_VALUE:
1518 #endif // ALG_CTR
1519 #if ALG_OFB
1520         case ALG_OFB_VALUE:
1521 #endif // ALG_OFB
1522 #if ALG_CBC
1523         case ALG_CBC_VALUE:
1524 #endif // ALG_CBC
1525 #if ALG_CFB
1526         case ALG_CFB_VALUE:
1527 #endif // ALG_CFB
1528 #if ALG_ECB
1529         case ALG_ECB_VALUE:
1530 #endif // ALG_ECB
1531             return TRUE;
1532         case ALG_NULL_VALUE:
1533             return flag;
1534             break;
1535         default:
1536             break;
1537     }
1538     return FALSE;
1539 }
```

10.2.7 CryptSelfTest.c

10.2.7.1 Introduction

The functions in this file are designed to support self-test of cryptographic functions in the TPM. The TPM allows the user to decide whether to run self-test on a demand basis or to run all the self-tests before proceeding.

The self-tests are controlled by a set of bit vectors. The *g_untestedDecryptionAlgorithms* vector has a bit for each decryption algorithm that needs to be tested and *g_untestedEncryptionAlgorithms* has a bit for each encryption algorithm that needs to be tested. Before an algorithm is used, the appropriate vector is checked (indexed using the algorithm ID). If the bit is 1, then the test function should be called.

For more information, see TpmSelfTests().txt

```
1   #include "Tpm.h"
```

10.2.7.2 Functions

10.2.7.2.1 RunSelfTest()

Local function to run self-test

```
2   static TPM_RC
3   CryptRunSelfTests(
4       ALGORITHM_VECTOR    *toTest         // IN: the vector of the algorithms to test
5       )
6   {
7       TPM_ALG_ID           alg;
8
9       // For each of the algorithms that are in the toTestVecor, need to run a
10      // test
11      for(alg = TPM_ALG_FIRST; alg <= TPM_ALG_LAST; alg++)
12      {
13          if(TEST_BIT(alg, *toTest))
14          {
15              TPM_RC          result = CryptTestAlgorithm(alg, toTest);
16              if(result != TPM_RC_SUCCESS)
17                  return result;
18          }
19      }
20      return TPM_RC_SUCCESS;
21  }
```

10.2.7.2.2 CryptSelfTest()

This function is called to start/complete a full self-test. If *fullTest* is NO, then only the untested algorithms will be run. If *fullTest* is YES, then *g_untestedDecryptionAlgorithms* is reinitialized and then all tests are run. This implementation of the reference design does not support processing outside the framework of a TPM command. As a consequence, this command does not complete until all tests are done. Since this can take a long time, the TPM will check after each test to see if the command is canceled. If so, then the TPM will returned TPM_RC_CANCELLED. To continue with the self-tests, call TPM2_SelfTest(*fullTest* == No) and the TPM will complete the testing.

 Copyright © TCG 2006-2020

Error Returns	Meaning
TPM_RC_CANCELED	if the command is canceled

```
22  LIB_EXPORT
23  TPM_RC
24  CryptSelfTest(
25      TPMI_YES_NO      fullTest       // IN: if full test is required
26      )
27  {
28  #if SIMULATION
29      if(g_forceFailureMode)
30          FAIL(FATAL_ERROR_FORCED);
31  #endif
32
33      // If the caller requested a full test, then reset the to test vector so that
34      // all the tests will be run
35      if(fullTest == YES)
36      {
37          MemoryCopy(g_toTest,
38                     g_implementedAlgorithms,
39                     sizeof(g_toTest));
40      }
41      return CryptRunSelfTests(&g_toTest);
42  }
```

10.2.7.2.3 CryptIncrementalSelfTest()

This function is used to perform an incremental self-test. This implementation will perform the *toTest* values before returning. That is, it assumes that the TPM cannot perform background tasks between commands.

This command may be canceled. If it is, then there is no return result. However, this command can be run again and the incremental progress will not be lost.

Error Returns	Meaning
TPM_RC_CANCELED	processing of this command was canceled
TPM_RC_TESTING	if *toTest* list is not empty
TPM_RC_VALUE	an algorithm in the *toTest* list is not implemented

```
43  TPM_RC
44  CryptIncrementalSelfTest(
45      TPML_ALG            *toTest,        // IN: list of algorithms to be tested
46      TPML_ALG            *toDoList       // OUT: list of algorithms needing test
47      )
48  {
49      ALGORITHM_VECTOR     toTestVector = {0};
50      TPM_ALG_ID           alg;
51      UINT32               i;
52
53      pAssert(toTest != NULL && toDoList != NULL);
54      if(toTest->count > 0)
55      {
56          // Transcribe the toTest list into the toTestVector
57          for(i = 0; i < toTest->count; i++)
58          {
59              alg = toTest->algorithms[i];
60
61              // make sure that the algorithm value is not out of range
62              if((alg > TPM_ALG_LAST) || !TEST_BIT(alg, g_implementedAlgorithms))
```

```
63                  return TPM_RC_VALUE;
64              SET_BIT(alg, toTestVector);
65          }
66          // Run the test
67          if(CryptRunSelfTests(&toTestVector) == TPM_RC_CANCELED)
68              return TPM_RC_CANCELED;
69      }
70      // Fill in the toDoList with the algorithms that are still untested
71      toDoList->count = 0;
72
73      for(alg = TPM_ALG_FIRST;
74      toDoList->count < MAX_ALG_LIST_SIZE && alg <= TPM_ALG_LAST;
75          alg++)
76      {
77          if(TEST_BIT(alg, g_toTest))
78              toDoList->algorithms[toDoList->count++] = alg;
79      }
80      return TPM_RC_SUCCESS;
81  }
```

10.2.7.2.4 CryptInitializeToTest()

This function will initialize the data structures for testing all the algorithms.

```
82  void
83  CryptInitializeToTest(
84      void
85      )
86  {
87      // Indicate that nothing has been tested
88      memset(&g_cryptoSelfTestState, 0, sizeof(g_cryptoSelfTestState));
89
90      // Copy the implemented algorithm vector
91      MemoryCopy(g_toTest, g_implementedAlgorithms, sizeof(g_toTest));
92
93      // Setting the algorithm to null causes the test function to just clear
94      // out any algorithms for which there is no test.
95      CryptTestAlgorithm(TPM_ALG_ERROR, &g_toTest);
96
97      return;
98  }
```

10.2.7.2.5 CryptTestAlgorithm()

Only point of contact with the actual self tests. If a self-test fails, there is no return and the TPM goes into failure mode. The call to TestAlgorithm() uses an algorithm selector and a bit vector. When the test is run, the corresponding bit in *toTest* and in *g_toTest* is CLEAR. If *toTest* is NULL, then only the bit in *g_toTest* is CLEAR. There is a special case for the call to TestAlgorithm(). When *alg* is ALG_ERROR, TestAlgorithm() will CLEAR any bit in *toTest* for which it has no test. This allows the knowledge about which algorithms have test to be accessed through the interface that provides the test.

Error Returns	Meaning
TPM_RC_CANCELED	test was canceled

```
99  LIB_EXPORT
100 TPM_RC
101 CryptTestAlgorithm(
102     TPM_ALG_ID          alg,
103     ALGORITHM_VECTOR   *toTest
104     )
105 {
```

 Copyright © TCG 2006-2020

```
106         TPM_RC                   result;
107     #if SELF_TEST
108         result = TestAlgorithm(alg, toTest);
109     #else
110         // If this is an attempt to determine the algorithms for which there is a
111         // self test, pretend that all of them do. We do that by not clearing any
112         // of the algorithm bits. When/if this function is called to run tests, it
113         // will over report. This can be changed so that any call to check on which
114         // algorithms have tests, 'toTest' can be cleared.
115         if(alg != TPM_ALG_ERROR)
116         {
117             CLEAR_BIT(alg, g_toTest);
118             if(toTest != NULL)
119                 CLEAR_BIT(alg, *toTest);
120         }
121         result = TPM_RC_SUCCESS;
122     #endif
123         return result;
124     }
```

10.2.8 CryptEccData.c

```
1    #include "Tpm.h"
2    #include "OIDs.h"
```

This file contains the ECC curve data. The format of the data depends on the setting of USE_BN_ECC_DATA. If it is defined, then the TPM's BigNum() format is used. Otherwise, it is kept in TPM2B format. The purpose of having the data in BigNum() format is so that it does not have to be reformatted before being used by the crypto library.

```
3    #if ALG_ECC

38  //*** CryptSetOddByteParity()
39  // This function sets the per byte parity of a 64-bit value. The least-significant
40  // bit is of each byte is replaced with the odd parity of the other 7 bits in the
41  // byte. With odd parity, no byte will ever be 0x00.
42  UINT64
43  CryptSetOddByteParity(
44      UINT64          k
45      )
46  {
47  #define PMASK 0x0101010101010101ULL
48      UINT64          out;
49      k |= PMASK;     // set the parity bit
50      out = k;
51      k ^= k >> 4;
52      k ^= k >> 2;
53      k ^= k >> 1;
```

```
54      k &= PMASK;       // odd parity extracted
55      out ^= k;         // out is now even parity because parity bit was already set
56      out ^= PMASK;     // out is now even parity
57      return out;
58  }
```

10.2.9.2.1 CryptDesIsWeakKey()

Check to see if a DES key is on the list of weak, semi-weak, or possibly weak keys.

Return Value	Meaning
TRUE(1)	DES key is weak
FALSE(0)	DES key is not weak

```
59  static BOOL
60  CryptDesIsWeakKey(
61      UINT64              k
62      )
63  {
64      int                i;
65  //
66      for(i = 0; i < DES_NUM_WEAK; i++)
67      {
68          if(k == DesWeakKeys[i])
69              return TRUE;
70      }
71      return FALSE;
72  }
```

10.2.9.2.2 CryptDesValidateKey()

Function to check to see if the input key is a valid DES key where the definition of valid is that none of the elements are on the list of weak, semi-weak, or possibly weak keys; and that for two keys, K1!=K2, and for three keys that K1!=K2 and K2!=K3.

```
73  BOOL
74  CryptDesValidateKey(
75      TPM2B_SYM_KEY       *desKey     // IN: key to validate
76      )
77  {
78      UINT64               k[3];
79      int                  i;
80      int                  keys = (desKey->t.size + 7) / 8;
81      BYTE                *pk = desKey->t.buffer;
82      BOOL                 ok;
83  //
84      // Note: 'keys' is the number of keys, not the maximum index for 'k'
85      ok = ((keys == 2) || (keys == 3)) && ((desKey->t.size % 8) == 0);
86      for(i = 0; ok && i < keys; pk += 8, i++)
87      {
88          k[i] = CryptSetOddByteParity(BYTE_ARRAY_TO_UINT64(pk));
89          ok = !CryptDesIsWeakKey(k[i]);
90      }
91      ok = ok && k[0] != k[1];
92      if(keys == 3)
93          ok = ok && k[1] != k[2];
94      return ok;
95  }
```

10.2.10 CryptEccKeyExchange.c

10.2.10.1 Introduction

This file contains the functions that are used for the two-phase, ECC, key-exchange protocols

```
1   #include "Tpm.h"
2   #if CC_ZGen_2Phase == YES
```

10.2.10.2 Functions

```
3   #if ALG_ECMQV
```

10.2.10.2.1 avf1()

This function does the associated value computation required by MQV key exchange. Process:

a) Convert *xQ* to an integer *xqi* using the convention specified in Appendix C.3.

b) Calculate xqm = xqi mod 2^ceil(f/2) (where f = ceil(log2(n)).

c) Calculate the associate value function avf(Q) = xqm + 2ceil(f / 2) Always returns TRUE(1).

```
4   static BOOL
5   avf1(
6       bigNum                bnX,            // IN/OUT: the reduced value
7       bigNum                bnN             // IN: the order of the curve
8       )
9   {
10  // compute f = 2^(ceil(ceil(log2(n)) / 2))
11      int                       f = (BnSizeInBits(bnN) + 1) / 2;
12  // x' = 2^f + (x mod 2^f)
13      BnMaskBits(bnX, f);    // This is mod 2*2^f but it doesn't matter because
14                              // the next operation will SET the extra bit anyway
15      BnSetBit(bnX, f);
16      return TRUE;
17  }
```

10.2.10.2.2 C_2_2_MQV()

This function performs the key exchange defined in SP800-56A 6.1.1.4 Full MQV, C(2, 2, ECC MQV).

CAUTION: Implementation of this function may require use of essential claims in patents not owned by TCG members.

Points *QsB* and *QeB* are required to be on the curve of *inQsA*. The function will fail, possibly catastrophically, if this is not the case.

Error Returns	Meaning
TPM_RC_NO_RESULT	the value for *dsA* does not give a valid point on the curve

```
18  static TPM_RC
19  C_2_2_MQV(
20      TPMS_ECC_POINT          *outZ,          // OUT: the computed point
21      TPM_ECC_CURVE            curveId,       // IN: the curve for the computations
22      TPM2B_ECC_PARAMETER     *dsA,           // IN: static private TPM key
23      TPM2B_ECC_PARAMETER     *deA,           // IN: ephemeral private TPM key
24      TPMS_ECC_POINT          *QsB,           // IN: static public party B key
25      TPMS_ECC_POINT          *QeB            // IN: ephemeral public party B key
```

```

10.2.10.2.5 ComputeWForSM2()

Compute the value for w used by SM2

```
184 static UINT32
185 ComputeWForSM2(
186     bigCurve        E
187     )
188 {
189     //  w := ceil(ceil(log2(n)) / 2) - 1
190     return (BnMsb(CurveGetOrder(AccessCurveData(E))) / 2 - 1);
191 }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

10.2.10.2.6 avfSm2()

This function does the associated value computation required by SM2 key exchange. This is different from the avf() in the international standards because it returns a value that is half the size of the value returned by the standard avf(). For example, if *n* is 15, *Ws* (*w* in the standard) is 2 but the *W* here is 1. This means that an input value of 14 (1110b) would return a value of 110b with the standard but 10b with the scheme in SM2.

```
192 static bigNum
193 avfSm2(
194     bigNum              bn,           // IN/OUT: the reduced value
195     UINT32              w              // IN: the value of w
196     )
197 {
198     // a)   set w := ceil(ceil(log2(n)) / 2) - 1
199     // b)   set x' := 2^w + ( x & (2^w - 1))
200     // This is just like the avf for MQV where x' = 2^w + (x mod 2^w)
201
202     BnMaskBits(bn, w);   // as with avf1, this is too big by a factor of 2 but
203                          // it doesn't matter because we SET the extra bit
204                          // anyway
205     BnSetBit(bn, w);
206     return bn;
207 }
```

10.2.10.2.7 SM2KeyExchange()

This function performs the key exchange defined in SM2. The first step is to compute *tA* = (*dsA* + *deA* avf(Xe,A)) mod *n* Then, compute the *Z* value from *outZ* = (*h tA* mod *n*) (*QsA* + [avf(*QeB.x*)](*QeB*)). The function will compute the ephemeral public key from the ephemeral private key. All points are required to be on the curve of *inQsA*. The function will fail catastrophically if this is not the case

Error Returns	Meaning
TPM_RC_NO_RESULT	the value for *dsA* does not give a valid point on the curve

```
208 LIB_EXPORT TPM_RC
209 SM2KeyExchange(
210     TPMS_ECC_POINT         *outZ,         // OUT: the computed point

10.2.11 CryptEccMain.c

10.2.11.1 Includes and Defines

```
1  #include "Tpm.h"
2  #if ALG_ECC
```

This version requires that the new format for ECC data be used

```
3  #if !USE_BN_ECC_DATA
4  #error "Need to SET USE_BN_ECC_DATA to YES in Implementaion.h"
5  #endif
```

10.2.11.2 Functions

```
6  #if SIMULATION
7  void
8  EccSimulationEnd(
9      void
10     )
11 {
12 #if SIMULATION
13 // put things to be printed at the end of the simulation here
14 #endif
15 }
16 #endif // SIMULATION
```

10.2.11.2.1 CryptEccInit()

This function is called at _TPM_Init()

```
17 BOOL
18 CryptEccInit(
19     void
20     )
21 {
22     return TRUE;
23 }
```

10.2.11.2.2 CryptEccStartup()

This function is called at TPM2_Startup().

```
24 BOOL
25 CryptEccStartup(
26     void
27     )
28 {
29     return TRUE;
30 }
```

10.2.11.2.3 ClearPoint2B(generic

Initialize the size values of a TPMS_ECC_POINT structure.

```
31 void
32 ClearPoint2B(
33     TPMS_ECC_POINT      *p          // IN: the point
```

 Copyright © TCG 2006-2020

```
34          )
35      {
36          if(p != NULL)
37          {
38              p->x.t.size = 0;
39              p->y.t.size = 0;
40          }
41      }
```

10.2.11.2.4 CryptEccGetParametersByCurveId()

This function returns a pointer to the curve data that is associated with the indicated *curveId*. If there is no curve with the indicated ID, the function returns NULL. This function is in this module so that it can be called by GetCurve() data.

Return Value	Meaning
NULL	curve with the indicated TPM_ECC_CURVE is not implemented
NULL	pointer to the curve data

```
42      LIB_EXPORT const ECC_CURVE *
43      CryptEccGetParametersByCurveId(
44          TPM_ECC_CURVE       curveId     // IN: the curveID
45          )
46      {
47          int           i;
48          for(i = 0; i < ECC_CURVE_COUNT; i++)
49          {
50              if(eccCurves[i].curveId == curveId)
51                  return &eccCurves[i];
52          }
53          return NULL;
54      }
```

10.2.11.2.5 CryptEccGetKeySizeForCurve()

This function returns the key size in bits of the indicated curve.

```
55      LIB_EXPORT UINT16
56      CryptEccGetKeySizeForCurve(
57          TPM_ECC_CURVE            curveId    // IN: the curve
58          )
59      {
60          const ECC_CURVE *curve = CryptEccGetParametersByCurveId(curveId);
61          UINT16          keySizeInBits;
62      //
63          keySizeInBits = (curve != NULL) ? curve->keySizeBits : 0;
64          return keySizeInBits;
65      }
```

10.2.11.2.6 GetCurveData()

This function returns the a pointer for the parameter data associated with a curve.

```
66      const ECC_CURVE_DATA *
67      GetCurveData(
68          TPM_ECC_CURVE        curveId     // IN: the curveID
69          )
70      {
71          const ECC_CURVE      *curve = CryptEccGetParametersByCurveId(curveId);
```

```
72         return (curve != NULL) ? curve->curveData : NULL;
73     }
```

10.2.11.2.7 CryptEccGetOID()

```
74     const BYTE *
75     CryptEccGetOID(
76         TPM_ECC_CURVE        curveId
77     )
78     {
79         const ECC_CURVE          *curve = CryptEccGetParametersByCurveId(curveId);
80         return (curve != NULL) ? curve->OID : NULL;
81     }
```

10.2.11.2.8 CryptEccGetCurveByIndex()

This function returns the number of the *i*-th implemented curve. The normal use would be to call this function with *i* starting at 0. When the *i* is greater than or equal to the number of implemented curves, TPM_ECC_NONE is returned.

```
82     LIB_EXPORT TPM_ECC_CURVE
83     CryptEccGetCurveByIndex(
84         UINT16               i
85         )
86     {
87         if(i >= ECC_CURVE_COUNT)
88             return TPM_ECC_NONE;
89         return eccCurves[i].curveId;
90     }
```

10.2.11.2.9 CryptEccGetParameter()

This function returns an ECC curve parameter. The parameter is selected by a single character designator from the set of "PNABXYH".

Return Value	Meaning
TRUE(1)	curve exists and parameter returned
FALSE(0)	curve does not exist or parameter selector

```
91     LIB_EXPORT BOOL
92     CryptEccGetParameter(
93         TPM2B_ECC_PARAMETER     *out,       // OUT: place to put parameter
94         char                     p,         // IN: the parameter selector
95         TPM_ECC_CURVE            curveId    // IN: the curve id
96         )
97     {
98         const ECC_CURVE_DATA    *curve = GetCurveData(curveId);
99         bigConst                 parameter = NULL;
100
101        if(curve != NULL)
102        {
103            switch(p)
104            {
105                case 'p':
106                    parameter = CurveGetPrime(curve);
107                    break;
108                case 'n':
109                    parameter = CurveGetOrder(curve);
110                    break;
```

 Copyright © TCG 2006-2020

```
111             case 'a':
112                 parameter = CurveGet_a(curve);
113                 break;
114             case 'b':
115                 parameter = CurveGet_b(curve);
116                 break;
117             case 'x':
118                 parameter = CurveGetGx(curve);
119                 break;
120             case 'y':
121                 parameter = CurveGetGy(curve);
122                 break;
123             case 'h':
124                 parameter = CurveGetCofactor(curve);
125                 break;
126             default:
127                 FAIL(FATAL_ERROR_INTERNAL);
128                 break;
129         }
130     }
131     // If not debugging and we get here with parameter still NULL, had better
132     // not try to convert so just return FALSE instead.
133     return (parameter != NULL) ? BnTo2B(parameter, &out->b, 0) : 0;
134 }
```

10.2.11.2.10 CryptCapGetECCCurve()

This function returns the list of implemented ECC curves.

Return Value	Meaning
YES	if no more ECC curve is available
NO	if there are more ECC curves not reported

```
135 TPMI_YES_NO
136 CryptCapGetECCCurve(
137     TPM_ECC_CURVE    curveID,       // IN: the starting ECC curve
138     UINT32           maxCount,      // IN: count of returned curves
139     TPML_ECC_CURVE  *curveList      // OUT: ECC curve list
140     )
141 {
142     TPMI_YES_NO       more = NO;
143     UINT16            i;
144     UINT32            count = ECC_CURVE_COUNT;
145     TPM_ECC_CURVE     curve;
146
147     // Initialize output property list
148     curveList->count = 0;
149
150     // The maximum count of curves we may return is MAX_ECC_CURVES
151     if(maxCount > MAX_ECC_CURVES) maxCount = MAX_ECC_CURVES;
152
153     // Scan the eccCurveValues array
154     for(i = 0; i < count; i++)
155     {
156         curve = CryptEccGetCurveByIndex(i);
157         // If curveID is less than the starting curveID, skip it
158         if(curve < curveID)
159             continue;
160         if(curveList->count < maxCount)
161         {
162             // If we have not filled up the return list, add more curves to
163             // it
```

 Copyright © TCG 2006-2020

```
164                 curveList->eccCurves[curveList->count] = curve;
165                 curveList->count++;
166             }
167             else
168             {
169                 // If the return list is full but we still have curves
170                 // available, report this and stop iterating
171                 more = YES;
172                 break;
173             }
174         }
175         return more;
176     }
```

10.2.11.2.11 CryptGetCurveSignScheme()

This function will return a pointer to the scheme of the curve.

```
177     const TPMT_ECC_SCHEME *
178     CryptGetCurveSignScheme(
179         TPM_ECC_CURVE     curveId        // IN: The curve selector
180         )
181     {
182         const ECC_CURVE          *curve = CryptEccGetParametersByCurveId(curveId);
183
184         if(curve != NULL)
185             return &(curve->sign);
186         else
187             return NULL;
188     }
```

10.2.11.2.12 CryptGenerateR()

This function computes the commit random value for a split signing scheme.

If *c* is NULL, it indicates that *r* is being generated for TPM2_Commit(). If *c* is not NULL, the TPM will validate that the *gr.commitArray* bit associated with the input value of *c* is SET. If not, the TPM returns FALSE and no *r* value is generated.

Return Value	Meaning
TRUE(1)	r value computed
FALSE(0)	no r value computed

```
189     BOOL
190     CryptGenerateR(
191         TPM2B_ECC_PARAMETER     *r,             // OUT: the generated random value
192         UINT16                  *c,             // IN/OUT: count value.
193         TPMI_ECC_CURVE           curveID,       // IN: the curve for the value
194         TPM2B_NAME              *name           // IN: optional name of a key to
195                                                 //     associate with 'r'
196         )
197     {
198         // This holds the marshaled g_commitCounter.
199         TPM2B_TYPE(8B, 8);
200         TPM2B_8B                 cntr = {{8,{0}}};
201         UINT32                   iterations;
202         TPM2B_ECC_PARAMETER      n;
203         UINT64                   currentCount = gr.commitCounter;
204         UINT16                   t1;
205     //
206         if(!CryptEccGetParameter(&n, 'n', curveID))
```

```
207             return FALSE;
208
209         // If this is the commit phase, use the current value of the commit counter
210         if(c != NULL)
211         {
212             // if the array bit is not set, can't use the value.

10.2.11.2.13 CryptCommit()

This function is called when the count value is committed. The *gr.commitArray* value associated with the current count value is SET and *g_commitCounter* is incremented. The low-order 16 bits of old value of the counter is returned.

```
266 UINT16
267 CryptCommit(
268     void
269     )
270 {
271     UINT16      oldCount = (UINT16)gr.commitCounter;
272     gr.commitCounter++;
273     SET_BIT(oldCount & COMMIT_INDEX_MASK, gr.commitArray);
274     return oldCount;
275 }
```

10.2.11.2.14 CryptEndCommit()

This function is called when the signing operation using the committed value is completed. It clears the gr.*commitArray* bit associated with the count value so that it can't be used again.

```
276 void
277 CryptEndCommit(
278     UINT16          c               // IN: the counter value of the commitment
279     )
280 {
281     ClearBit((c & COMMIT_INDEX_MASK), gr.commitArray, sizeof(gr.commitArray));
282 }
```

10.2.11.2.15 CryptEccGetParameters()

This function returns the ECC parameter details of the given curve.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	unsupported ECC curve ID

```
283 BOOL
284 CryptEccGetParameters(
285     TPM_ECC_CURVE                curveId,       // IN: ECC curve ID
286     TPMS_ALGORITHM_DETAIL_ECC   *parameters     // OUT: ECC parameters
287     )
288 {
289     const ECC_CURVE             *curve = CryptEccGetParametersByCurveId(curveId);
290     const ECC_CURVE_DATA        *data;
291     BOOL                         found = curve != NULL;
292
293     if(found)
294     {
295         data = curve->curveData;
296         parameters->curveID = curve->curveId;
297         parameters->keySize = curve->keySizeBits;
298         parameters->kdf = curve->kdf;
299         parameters->sign = curve->sign;
300 //        BnTo2B(data->prime, &parameters->p.b, 0);
301         BnTo2B(data->prime, &parameters->p.b, parameters->p.t.size);
302         BnTo2B(data->a, &parameters->a.b, 0);
303         BnTo2B(data->b, &parameters->b.b, 0);
304         BnTo2B(data->base.x, &parameters->gX.b, parameters->p.t.size);
```

 Copyright © TCG 2006-2020

```
305             BnTo2B(data->base.y, &parameters->gY.b, parameters->p.t.size);
306     //          BnTo2B(data->base.x, &parameters->gX.b, 0);
307     //          BnTo2B(data->base.y, &parameters->gY.b, 0);
308             BnTo2B(data->order, &parameters->n.b, 0);
309             BnTo2B(data->h, &parameters->h.b, 0);
310         }
311         return found;
312     }
```

10.2.11.2.16 BnGetCurvePrime()

This function is used to get just the prime modulus associated with a curve.

```
313     const bignum_t *
314     BnGetCurvePrime(
315         TPM_ECC_CURVE            curveId
316         )
317     {
318         const ECC_CURVE_DATA    *C = GetCurveData(curveId);
319         return (C != NULL) ? CurveGetPrime(C) : NULL;
320     }
```

10.2.11.2.17 BnGetCurveOrder()

This function is used to get just the curve order

```
321     const bignum_t *
322     BnGetCurveOrder(
323         TPM_ECC_CURVE            curveId
324         )
325     {
326         const ECC_CURVE_DATA    *C = GetCurveData(curveId);
327         return (C != NULL) ? CurveGetOrder(C) : NULL;
328     }
```

10.2.11.2.18 BnIsOnCurve()

This function checks if a point is on the curve.

```
329     BOOL
330     BnIsOnCurve(
331         pointConst                   Q,
332         const ECC_CURVE_DATA        *C
333         )
334     {
335         BN_VAR(right, (MAX_ECC_KEY_BITS * 3));
336         BN_VAR(left, (MAX_ECC_KEY_BITS * 2));
337         bigConst                    prime = CurveGetPrime(C);
338     //
339         // Show that point is on the curve y^2 = x^3 + ax + b;
340         // Or y^2 = x(x^2 + a) + b
341         // y^2
342         BnMult(left, Q->y, Q->y);
343
344         BnMod(left, prime);
345     // x^2
346         BnMult(right, Q->x, Q->x);
347
348         // x^2 + a
349         BnAdd(right, right, CurveGet_a(C));
350
```

```
351 //    BnMod(right, CurveGetPrime(C));
352     // x(x^2 + a)
353     BnMult(right, right, Q->x);
354
355     // x(x^2 + a) + b
356     BnAdd(right, right, CurveGet_b(C));
357
358     BnMod(right, prime);
359     if(BnUnsignedCmp(left, right) == 0)
360         return TRUE;
361     else
362         return FALSE;
363 }
```

10.2.11.2.19 BnIsValidPrivateEcc()

Checks that 0 < *x* < *q*

```
364 BOOL
365 BnIsValidPrivateEcc(
366     bigConst                 x,         // IN: private key to check
367     bigCurve                 E          // IN: the curve to check
368     )
369 {
370     BOOL         retVal;
371     retVal = (!BnEqualZero(x)
372               && (BnUnsignedCmp(x, CurveGetOrder(AccessCurveData(E))) < 0));
373     return retVal;
374 }
375 LIB_EXPORT BOOL
376 CryptEccIsValidPrivateKey(
377     TPM2B_ECC_PARAMETER     *d,
378     TPM_ECC_CURVE            curveId
379     )
380 {
381     BN_INITIALIZED(bnD, MAX_ECC_PARAMETER_BYTES * 8, d);
382     return !BnEqualZero(bnD) && (BnUnsignedCmp(bnD, BnGetCurveOrder(curveId)) < 0);
383 }
```

10.2.11.2.20 BnPointMul()

This function does a point multiply of the form *R* = [*d*]*S* + [*u*]Q where the parameters are *bigNum* values. If *S* is NULL and d is not NULL, then it computes *R* = [*d*]*G* + [*u*]*Q* or just *R* = [*d*]*G* if *u* and *Q* are NULL. If *skipChecks* is TRUE, then the function will not verify that the inputs are correct for the domain. This would be the case when the values were created by the CryptoEngine() code. It will return TPM_RC_NO_RESULT if the resulting point is the point at infinity.

Error Returns	Meaning
TPM_RC_NO_RESULT	result of multiplication is a point at infinity
TPM_RC_ECC_POINT	*S* or *Q* is not on the curve
TPM_RC_VALUE	*d* or *u* is not < n

```
384 TPM_RC
385 BnPointMult(
386     bigPoint             R,          // OUT: computed point
387     pointConst           S,          // IN: optional point to multiply by 'd'
388     bigConst             d,          // IN: scalar for [d]S or [d]G
389     pointConst           Q,          // IN: optional second point
390     bigConst             u,          // IN: optional second scalar
```

```
391         bigCurve                  E            // IN: curve parameters
392         )
393     {
394         BOOL                      OK;
395     //
396         TEST(TPM_ALG_ECDH);
397
398         // Need one scalar
399         OK = (d != NULL || u != NULL);
400
401         // If S is present, then d has to be present. If S is not
402         // present, then d may or may not be present
403         OK = OK && (((S == NULL) == (d == NULL)) || (d != NULL));
404
405         // either both u and Q have to be provided or neither can be provided (don't
406         // know what to do if only one is provided.
407         OK = OK && ((u == NULL) == (Q == NULL));
408
409         OK = OK && (E != NULL);
410         if(!OK)
411             return TPM_RC_VALUE;
412
413         OK = (S == NULL) || BnIsOnCurve(S, AccessCurveData(E));
414         OK = OK && ((Q == NULL) || BnIsOnCurve(Q, AccessCurveData(E)));
415         if(!OK)
416             return TPM_RC_ECC_POINT;
417
418         if((d != NULL) && (S == NULL))
419             S = CurveGetG(AccessCurveData(E));
420         // If only one scalar, don't need Shamir's trick
421         if((d == NULL) || (u == NULL))
422         {
423             if(d == NULL)
424                 OK = BnEccModMult(R, Q, u, E);
425             else
426                 OK = BnEccModMult(R, S, d, E);
427         }
428         else
429         {
430             OK = BnEccModMult2(R, S, d, Q, u, E);
431         }
432         return  (OK ? TPM_RC_SUCCESS : TPM_RC_NO_RESULT);
433     }
```

10.2.11.2.21 BnEccGetPrivate()

This function gets random values that are the size of the key plus 64 bits. The value is reduced (mod (q - 1)) and incremented by 1 (q is the order of the curve. This produces a value (d) such that 1 <= d < q. This is the method of FIPS 186-4 Section B.4.1 "Key Pair Generation Using Extra Random Bits".

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure generating private key

```
434     BOOL
435     BnEccGetPrivate(
436         bigNum                     dOut,        // OUT: the qualified random value
437         const ECC_CURVE_DATA      *C,           // IN: curve for which the private key
438                                                 //     needs to be appropriate
439         RAND_STATE                *rand         // IN: state for DRBG
440         )
441     {
```

```
442       bigConst                  order = CurveGetOrder(C);
443       BOOL                      OK;
444       UINT32                    orderBits = BnSizeInBits(order);
445       UINT32                    orderBytes = BITS_TO_BYTES(orderBits);
446       BN_VAR(bnExtraBits, MAX_ECC_KEY_BITS + 64);
447       BN_VAR(nMinus1, MAX_ECC_KEY_BITS);
448   //
449       OK = BnGetRandomBits(bnExtraBits, (orderBytes * 8) + 64, rand);
450       OK = OK && BnSubWord(nMinus1, order, 1);
451       OK = OK && BnMod(bnExtraBits, nMinus1);
452       OK = OK && BnAddWord(dOut, bnExtraBits, 1);
453       return OK && !g_inFailureMode;
454   }
```

10.2.11.2.22 BnEccGenerateKeyPair()

This function gets a private scalar from the source of random bits and does the point multiply to get the public key.

```
455   BOOL
456   BnEccGenerateKeyPair(
457       bigNum               bnD,             // OUT: private scalar
458       bn_point_t          *ecQ,             // OUT: public point
459       bigCurve             E,               // IN: curve for the point
460       RAND_STATE          *rand             // IN: DRBG state to use
461       )
462   {
463       BOOL                 OK = FALSE;
464       // Get a private scalar
465       OK = BnEccGetPrivate(bnD, AccessCurveData(E), rand);
466
467       // Do a point multiply
468       OK = OK && BnEccModMult(ecQ, NULL, bnD, E);
469       if(!OK)
470           BnSetWord(ecQ->z, 0);
471       else
472           BnSetWord(ecQ->z, 1);
473       return OK;
474   }
```

10.2.11.2.23 CryptEccNewKeyPair

This function creates an ephemeral ECC. It is ephemeral in that is expected that the private part of the key will be discarded

```
475   LIB_EXPORT TPM_RC
476   CryptEccNewKeyPair(
477       TPMS_ECC_POINT          *Qout,      // OUT: the public point
478       TPM2B_ECC_PARAMETER     *dOut,      // OUT: the private scalar
479       TPM_ECC_CURVE            curveId    // IN: the curve for the key
480       )
481   {
482       CURVE_INITIALIZED(E, curveId);
483       POINT(ecQ);
484       ECC_NUM(bnD);
485       BOOL                    OK;
486
487       if(E == NULL)
488           return TPM_RC_CURVE;
489
490       TEST(TPM_ALG_ECDH);
491       OK = BnEccGenerateKeyPair(bnD, ecQ, E, NULL);
```

```
492         if(OK)
493         {
494             BnPointTo2B(Qout, ecQ, E);
495             BnTo2B(bnD, &dOut->b, Qout->x.t.size);
496         }
497         else
498         {
499             Qout->x.t.size = Qout->y.t.size = dOut->t.size = 0;
500         }
501         CURVE_FREE(E);
502         return OK ? TPM_RC_SUCCESS : TPM_RC_NO_RESULT;
503     }
```

10.2.11.2.24 CryptEccPointMultiply()

This function computes *R* := [*dIn*]*G* + [*uIn*]*QIn*. Where *dIn* and *uIn* are scalars, *G* and *QIn* are points on the specified curve and *G* is the default generator of the curve.

The *xOut* and *yOut* parameters are optional and may be set to NULL if not used.

It is not necessary to provide *uIn* if *QIn* is specified but one of *uIn* and *dIn* must be provided. If *dIn* and *QIn* are specified but *uIn* is not provided, then *R* = [*dIn*]*QIn*.

If the multiply produces the point at infinity, the TPM_RC_NO_RESULT is returned.

The sizes of *xOut* and *yOut*' will be set to be the size of the degree of the curve

It is a fatal error if *dIn* and *uIn* are both unspecified (NULL) or if *Qin* or *Rout* is unspecified.

Error Returns	Meaning
TPM_RC_ECC_POINT	the point *Pin* or *Qin* is not on the curve
TPM_RC_NO_RESULT	the product point is at infinity
TPM_RC_CURVE	bad curve
TPM_RC_VALUE	*dIn* or *uIn* out of range

```

532 }
```

10.2.11.2.25 CryptEccIsPointOnCurve()

This function is used to test if a point is on a defined curve. It does this by checking that *y*^2 mod *p* = *x*^3 + *a***x* + *b* mod *p*.

It is a fatal error if *Q* is not specified (is NULL).

Return Value	Meaning
TRUE(1)	point is on curve
FALSE(0)	point is not on curve or curve is not supported

```
533 LIB_EXPORT BOOL
534 CryptEccIsPointOnCurve(
535     TPM_ECC_CURVE            curveId,        // IN: the curve selector
536     TPMS_ECC_POINT          *Qin            // IN: the point.
537     )
538 {
539     const ECC_CURVE_DATA    *C = GetCurveData(curveId);
540     POINT_INITIALIZED(ecQ, Qin);
541     BOOL                OK;
542 //
543     pAssert(Qin != NULL);
544     OK = (C != NULL && (BnIsOnCurve(ecQ, C)));
545     return OK;
546 }
```

10.2.11.2.26 CryptEccGenerateKey()

This function generates an ECC key pair based on the input parameters. This routine uses KDFa to produce candidate numbers. The method is according to FIPS 186-3, section B.1.2 "Key Pair Generation by Testing Candidates." According to the method in FIPS 186-3, the resulting private value *d* should be 1 <= *d* < *n* where *n* is the order of the base point.

It is a fatal error if *Qout*, *dOut*, is not provided (is NULL).

If the curve is not supported If *seed* is not provided, then a random number will be used for the key

Error Returns	Meaning
TPM_RC_CURVE	curve is not supported
TPM_RC_NO_RESULT	could not verify key with signature (FIPS only)

```
547 LIB_EXPORT TPM_RC
548 CryptEccGenerateKey(
549     TPMT_PUBLIC         *publicArea,        // IN/OUT: The public area template for

```

10.2.12.2 Utility Functions

10.2.12.2.1 EcdsaDigest()

Function to adjust the digest so that it is no larger than the order of the curve. This is used for ECDSA sign and verification.

```
4 static bigNum
5 EcdsaDigest(
6     bigNum              bnD,           // OUT: the adjusted digest
7     const TPM2B_DIGEST  *digest,       // IN: digest to adjust
8     bigConst            max            // IN: value that indicates the maximum
9                                        //     number of bits in the results
10    )
11 {
12     int                 bitsInMax = BnSizeInBits(max);
13     int                 shift;
14 //
15     if(digest == NULL)
16         BnSetWord(bnD, 0);
17     else
18     {
19         BnFromBytes(bnD, digest->t.buffer,
20                     (NUMBYTES)MIN(digest->t.size, BITS_TO_BYTES(bitsInMax)));
21         shift = BnSizeInBits(bnD) - bitsInMax;
22         if(shift > 0)
23             BnShiftRight(bnD, bnD, shift);
24     }
25     return bnD;
26 }
```

10.2.12.2.2 BnSchnorrSign()

This contains the Schnorr signature computation. It is used by both ECDSA and Schnorr signing. The result is computed as: [$s = k + r * d \pmod{n}$] where

a) s is the signature

b) k is a random value

c) r is the value to sign

d) d is the private EC key

e) n is the order of the curve

Error Returns	Meaning
TPM_RC_NO_RESULT	the result of the operation was zero or $r \pmod{n}$ is zero

```
27 static TPM_RC
28 BnSchnorrSign(
29     bigNum                  bnS,         // OUT: 's' component of the signature
```

 Copyright © TCG 2006-2020

```
30      bigConst                bnK,          // IN: a random value
31      bigNum                  bnR,          // IN: the signature 'r' value
32      bigConst                bnD,          // IN: the private key
33      bigConst                bnN           // IN: the order of the curve
34      )
35  {
36      // Need a local temp value to store the intermediate computation because product
37      // size can be larger than will fit in bnS.
38      BN_VAR(bnT1, MAX_ECC_PARAMETER_BYTES * 2 * 8);
39  //
40      // Reduce bnR without changing the input value
41      BnDiv(NULL, bnT1, bnR, bnN);
42      if(BnEqualZero(bnT1))
43          return TPM_RC_NO_RESULT;
44      // compute s = (k + r * d)(mod n)
45          // r * d
46      BnMult(bnT1, bnT1, bnD);
47          // k * r * d
48      BnAdd(bnT1, bnT1, bnK);
49          // k + r * d (mod n)
50      BnDiv(NULL, bnS, bnT1, bnN);
51      return (BnEqualZero(bnS)) ? TPM_RC_NO_RESULT : TPM_RC_SUCCESS;
52  }
```

10.2.12.3 Signing Functions

10.2.12.3.1 BnSignEcdsa()

This function implements the ECDSA signing algorithm. The method is described in the comments below.

```
53  TPM_RC
54  BnSignEcdsa(
55      bigNum                  bnR,          // OUT: 'r' component of the signature
56      bigNum                  bnS,          // OUT: 's' component of the signature
57      bigCurve                E,            // IN: the curve used in the signature
58                                            //     process
59      bigNum                  bnD,          // IN: private signing key
60      const TPM2B_DIGEST     *digest,       // IN: the digest to sign
61      RAND_STATE             *rand          // IN: used in debug of signing
62      )
63  {
64      ECC_NUM(bnK);
65      ECC_NUM(bnIk);

122         BnModMult(bnS, bnIk, bnS, order);
123
124         // If S is zero, try again
125     } while(BnEqualZero(bnS));
126 Exit:
127     return retVal;
128 }
129 #if ALG_ECDAA
```

10.2.12.3.2 BnSignEcdaa()

This function performs $s = r + T * d \bmod q$ where

a) 'r is a random, or pseudo-random value created in the commit phase

b) *nonceK* is a TPM-generated, random value 0 < *nonceK* < *n*

c) *T* is mod *q* of **Hash**(*nonceK* || *digest*), and

d) *d* is a private key.

The signature is the tuple (*nonceK*, *s*)

Regrettably, the parameters in this function kind of collide with the parameter names used in ECSCHNORR making for a lot of confusion.

Error Returns	Meaning
TPM_RC_SCHEME	unsupported hash algorithm
TPM_RC_NO_RESULT	cannot get values from random number generator

```
130 static TPM_RC
131 BnSignEcdaa(
132     TPM2B_ECC_PARAMETER     *nonceK,        // OUT: 'nonce' component of the signature

```

10.2.12.3.3 SchnorrReduce()

Function to reduce a hash result if it's magnitude is too large. The size of *number* is set so that it has no more bytes of significance than *reference* value. If the resulting number can have more bits of significance than *reference*.

```
199     static void
200     SchnorrReduce(
201         TPM2B        *number,          // IN/OUT: Value to reduce
202         bigConst      reference        // IN: the reference value
203         )
204     {
205         UINT16       maxBytes = (UINT16)BITS_TO_BYTES(BnSizeInBits(reference));
206         if(number->size > maxBytes)
207             number->size = maxBytes;
208     }
```

10.2.12.3.4 SchnorrEcc()

This function is used to perform a modified Schnorr signature.

This function will generate a random value *k* and compute

a) $(xR, yR) = [k]G$

b) $r =$ **Hash**$(xR \,||\, P)(\text{mod } q)$

c) $rT =$ truncated r

d) $s = k + rT * ds \,(\text{mod } q)$

e) return the tuple rT, s

Error Returns	Meaning
TPM_RC_NO_RESULT	failure in the Schnorr sign process
TPM_RC_SCHEME	*hashAlg* can't produce zero-length digest

```
209     static TPM_RC

```

10.2.12.3.7 CryptEccSign()

This function is the dispatch function for the various ECC-based signing schemes. There is a bit of ugliness to the parameter passing. In order to test this, we sometime would like to use a deterministic RNG so that we can get the same signatures during testing. The easiest way to do this for most schemes is to pass in a deterministic RNG and let it return canned values during testing. There is a competing need for a canned parameter to use in ECDAA. To accommodate both needs with minimal fuss, a special type of RAND_STATE is defined to carry the address of the commit value. The setup and handling of this is not very different for the caller than what was in previous versions of the code.

Error Returns	Meaning
TPM_RC_SCHEME	*scheme* is not supported

```
372 LIB_EXPORT TPM_RC

10.2.12.3.12 CryptEccCommitCompute()

This function performs the point multiply operations required by TPM2_Commit().

If *B* or *M* is provided, they must be on the curve defined by *curveId*. This routine does not check that they are on the curve and results are unpredictable if they are not.

It is a fatal error if *r* is NULL. If *B* is not NULL, then it is a fatal error if *d* is NULL or if *K* and *L* are both NULL. If *M* is not NULL, then it is a fatal error if *E* is NULL.

Error Returns	Meaning
TPM_RC_NO_RESULT	if *K*, *L* or *E* was computed to be the point at infinity
TPM_RC_CANCELED	a cancel indication was asserted during this function

```
673 LIB_EXPORT TPM_RC

10.2.13 CryptHash.c

10.2.13.1 Description

This file contains implementation of cryptographic functions for hashing.

10.2.13.2 Includes, Defines, and Types

```
1   #define _CRYPT_HASH_C_
2   #include "Tpm.h"
3   #include "CryptHash_fp.h"
4   #include "CryptHash.h"
5   #include "OIDs.h"
6   #define HASH_TABLE_SIZE     (HASH_COUNT + 1)
7   #if     ALG_SHA1
8   HASH_DEF_TEMPLATE(SHA1, Sha1);
9   #endif
10  #if     ALG_SHA256
11  HASH_DEF_TEMPLATE(SHA256, Sha256);
12  #endif
13  #if     ALG_SHA384
14  HASH_DEF_TEMPLATE(SHA384, Sha384);
15  #endif
16  #if     ALG_SHA512
17  HASH_DEF_TEMPLATE(SHA512, Sha512);
18  #endif
19  #if ALG_SM3_256
20  HASH_DEF_TEMPLATE(SM3_256, Sm3_256);
21  #endif
22  HASH_DEF NULL_Def = {{0}};
23
24  PHASH_DEF       HashDefArray[] = {
25  #if ALG_SHA1
26      &Sha1_Def,
27  #endif
28  #if ALG_SHA256

42
43  //** Obligatory Initialization Functions
44
45  //*** CryptHashInit()
46  // This function is called by _TPM_Init do perform the initialization operations for
47  // the library.
48  BOOL
49  CryptHashInit(
50      void
51      )
52  {
53      LibHashInit();
54      return TRUE;
```

```
55 }
```

10.2.13.2.1 CryptHashStartup()

This function is called by TPM2_Startup(). It checks that the size of the HashDefArray() is consistent with the HASH_COUNT.

```
56 BOOL
57 CryptHashStartup(
58     void
59     )
60 {
61     int         i = sizeof(HashDefArray) / sizeof(PHASH_DEF) - 1;
62     return (i == HASH_COUNT);
63 }
```

10.2.13.3 Hash Information Access Functions

10.2.13.3.1 Introduction

These functions provide access to the hash algorithm description information.

10.2.13.3.2 CryptGetHashDef()

This function accesses the hash descriptor associated with a hash a algorithm. The function returns a pointer to a *null* descriptor if *hashAlg* is TPM_ALG_NULL or not a defined algorithm.

```
64 PHASH_DEF
65 CryptGetHashDef(
66     TPM_ALG_ID      hashAlg
67     )
68 {
69     size_t          i;
70 #define HASHES  (sizeof(HashDefArray) / sizeof(PHASH_DEF))
71     for(i = 0; i < HASHES; i++)
72     {
73         PHASH_DEF p = HashDefArray[i];
74         if(p->hashAlg == hashAlg)
75             return p;
76     }
77     return &NULL_Def;
78 }
```

10.2.13.3.3 CryptHashIsValidAlg()

This function tests to see if an algorithm ID is a valid hash algorithm. If flag is true, then TPM_ALG_NULL is a valid hash.

Return Value	Meaning
TRUE(1)	*hashAlg* is a valid, implemented hash on this TPM
FALSE(0)	*hashAlg* is not valid for this TPM

```
79 BOOL
80 CryptHashIsValidAlg(
81     TPM_ALG_ID      hashAlg,           // IN: the algorithm to check
82     BOOL            flag               // IN: TRUE if TPM_ALG_NULL is to be treated
83                                        //     as a valid hash
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
84      )
85  {
86      if(hashAlg == TPM_ALG_NULL)
87          return flag;
88      return CryptGetHashDef(hashAlg) != &NULL_Def;
89  }
```

10.2.13.3.4 CryptHashGetAlgByIndex()

This function is used to iterate through the hashes. TPM_ALG_NULL is returned for all indexes that are not valid hashes. If the TPM implements 3 hashes, then an *index* value of 0 will return the first implemented hash and an *index* of 2 will return the last. All other index values will return TPM_ALG_NULL.

Return Value	Meaning
TPM_ALG_xxx	a hash algorithm
TPM_ALG_NULL	this can be used as a stop value

```
90  LIB_EXPORT TPM_ALG_ID
91  CryptHashGetAlgByIndex(
92      UINT32          index           // IN: the index
93      )
94  {
95      TPM_ALG_ID      hashAlg;
96      if(index >= HASH_COUNT)
97          hashAlg = TPM_ALG_NULL;
98      else
99          hashAlg = HashDefArray[index]->hashAlg;
100     return hashAlg;
101 }
```

10.2.13.3.5 CryptHashGetDigestSize()

Returns the size of the digest produced by the hash. If *hashAlg* is not a hash algorithm, the TPM will FAIL.

Return Value	Meaning
0	TPM_ALG_NULL
0	the digest size

```
102 LIB_EXPORT UINT16
103 CryptHashGetDigestSize(
104     TPM_ALG_ID      hashAlg         // IN: hash algorithm to look up
105     )
106 {
107     return CryptGetHashDef(hashAlg)->digestSize;
108 }
```

10.2.13.3.6 CryptHashGetBlockSize()

Returns the size of the block used by the hash. If *hashAlg* is not a hash algorithm, the TPM will FAIL.

 Copyright © TCG 2006-2020

Return Value	Meaning
0	TPM_ALG_NULL
0	the digest size

```
109  LIB_EXPORT UINT16
110  CryptHashGetBlockSize(
111      TPM_ALG_ID       hashAlg         // IN: hash algorithm to look up
112      )
113  {
114      return CryptGetHashDef(hashAlg)->blockSize;
115  }
```

10.2.13.3.7 CryptHashGetOid()

This function returns a pointer to DER=encoded OID for a hash algorithm. All OIDs are full OID values including the Tag (0x06) and length byte.

```
116  LIB_EXPORT const BYTE *
117  CryptHashGetOid(
118      TPM_ALG_ID      hashAlg
119  )
120  {
121      return CryptGetHashDef(hashAlg)->OID;
122  }
```

10.2.13.3.8 CryptHashGetContextAlg()

This function returns the hash algorithm associated with a hash context.

```
123  TPM_ALG_ID
124  CryptHashGetContextAlg(
125      PHASH_STATE      state           // IN: the context to check
126      )
127  {
128      return state->hashAlg;
129  }
```

10.2.13.4 State Import and Export

10.2.13.4.1 CryptHashCopyState

This function is used to clone a HASH_STATE.

```
130  LIB_EXPORT void
131  CryptHashCopyState(
132      HASH_STATE          *out,           // OUT: destination of the state
133      const HASH_STATE    *in             // IN: source of the state
134      )
135  {
136      pAssert(out->type == in->type);
137      out->hashAlg = in->hashAlg;
138      out->def = in->def;
139      if(in->hashAlg != TPM_ALG_NULL)
140      {
141          HASH_STATE_COPY(out, in);
142      }
143      if(in->type == HASH_STATE_HMAC)
144      {
```

 Copyright © TCG 2006-2020

```
145             const HMAC_STATE     *hIn = (HMAC_STATE *)in;
146             HMAC_STATE           *hOut = (HMAC_STATE *)out;
147             hOut->hmacKey = hIn->hmacKey;
148         }
149         return;
150     }
```

10.2.13.4.2 CryptHashExportState()

This function is used to export a hash or HMAC hash state. This function would be called when preparing to context save a sequence object.

```
151     void
152     CryptHashExportState(
153         PCHASH_STATE         internalFmt,    // IN: the hash state formatted for use by
154                                              //     library
155         PEXPORT_HASH_STATE   externalFmt     // OUT: the exported hash state
156         )
157     {
158         BYTE                     *outBuf = (BYTE *)externalFmt;
159     //
160         cAssert(sizeof(HASH_STATE) <= sizeof(EXPORT_HASH_STATE));
161         // the following #define is used to move data from an aligned internal data
162         // structure to a byte buffer (external format data.
163     #define CopyToOffset(value)                                                  \
164             memcpy(&outBuf[offsetof(HASH_STATE,value)], &internalFmt->value,        \
165                     sizeof(internalFmt->value))
166         // Copy the hashAlg
167         CopyToOffset(hashAlg);
168         CopyToOffset(type);
169     #ifdef HASH_STATE_SMAC
170         if(internalFmt->type == HASH_STATE_SMAC)
171         {
172             memcpy(outBuf, internalFmt, sizeof(HASH_STATE));
173             return;
174
175         }
176     #endif
177         if(internalFmt->type == HASH_STATE_HMAC)
178         {
179             HMAC_STATE               *from = (HMAC_STATE *)internalFmt;
180             memcpy(&outBuf[offsetof(HMAC_STATE, hmacKey)], &from->hmacKey,
181                    sizeof(from->hmacKey));
182         }
183         if(internalFmt->hashAlg != TPM_ALG_NULL)
184              HASH_STATE_EXPORT(externalFmt, internalFmt);
185     }
```

10.2.13.4.3 CryptHashImportState()

This function is used to import the hash state. This function would be called to import a hash state when the context of a sequence object was being loaded.

```
186     void
187     CryptHashImportState(
188         PHASH_STATE          internalFmt,    // OUT: the hash state formatted for use by
189                                              //     the library
190         PCEXPORT_HASH_STATE  externalFmt     // IN: the exported hash state
191         )
192     {
193         BYTE                     *inBuf = (BYTE *)externalFmt;
194     //
```

```
195 #define CopyFromOffset(value)                                                    \
196     memcpy(&internalFmt->value, &inBuf[offsetof(HASH_STATE,value)],              \
197             sizeof(internalFmt->value))
198
199     // Copy the hashAlg of the byte-aligned input structure to the structure-aligned
200     // internal structure.
201     CopyFromOffset(hashAlg);
202     CopyFromOffset(type);
203     if(internalFmt->hashAlg != TPM_ALG_NULL)
204     {
205 #ifdef HASH_STATE_SMAC
206         if(internalFmt->type == HASH_STATE_SMAC)
207         {
208             memcpy(internalFmt, inBuf, sizeof(HASH_STATE));
209             return;
210         }
211 #endif
212         internalFmt->def = CryptGetHashDef(internalFmt->hashAlg);
213         HASH_STATE_IMPORT(internalFmt, inBuf);
214         if(internalFmt->type == HASH_STATE_HMAC)
215         {
216             HMAC_STATE              *to = (HMAC_STATE *)internalFmt;
217             memcpy(&to->hmacKey, &inBuf[offsetof(HMAC_STATE, hmacKey)],
218                     sizeof(to->hmacKey));
219         }
220     }
221 }
```

10.2.13.5 State Modification Functions

10.2.13.5.1 HashEnd()

Local function to complete a hash that uses the *hashDef* instead of an algorithm ID. This function is used to complete the hash and only return a partial digest. The return value is the size of the data copied.

```
222 static UINT16
223 HashEnd(
224     PHASH_STATE      hashState,     // IN: the hash state
225     UINT32           dOutSize,      // IN: the size of receive buffer
226     PBYTE            dOut           // OUT: the receive buffer
227     )
228 {
229     BYTE                temp[MAX_DIGEST_SIZE];
230     if((hashState->hashAlg == TPM_ALG_NULL)
231        || (hashState->type != HASH_STATE_HASH))
232         dOutSize = 0;
233     if(dOutSize > 0)
234     {
235         hashState->def = CryptGetHashDef(hashState->hashAlg);
236         // Set the final size
237         dOutSize = MIN(dOutSize, hashState->def->digestSize);
238         // Complete into the temp buffer and then copy
239         HASH_END(hashState, temp);
240         // Don't want any other functions calling the HASH_END method
241         // directly.
242 #undef HASH_END
243         memcpy(dOut, &temp, dOutSize);
244     }
245     hashState->type = HASH_STATE_EMPTY;
246     return (UINT16)dOutSize;
247 }
```

10.2.13.5.2 CryptHashStart()

Functions starts a hash stack Start a hash stack and returns the digest size. As a side effect, the value of *stateSize* in *hashState* is updated to indicate the number of bytes of state that were saved. This function calls GetHashServer() and that function will put the TPM into failure mode if the hash algorithm is not supported.

This function does not use the sequence parameter. If it is necessary to import or export context, this will start the sequence in a local state and export the state to the input buffer. Will need to add a flag to the state structure to indicate that it needs to be imported before it can be used. (BLEH).

Return Value	Meaning
0	hash is TPM_ALG_NULL
>0	digest size

```
248 LIB_EXPORT UINT16
249 CryptHashStart(
250     PHASH_STATE      hashState,      // OUT: the running hash state
251     TPM_ALG_ID       hashAlg         // IN: hash algorithm
252     )
253 {
254     UINT16               retVal;
255
256     TEST(hashAlg);
257
258     hashState->hashAlg = hashAlg;
259     if(hashAlg == TPM_ALG_NULL)
260     {
261         retVal = 0;
262     }
263     else
264     {
265         hashState->def = CryptGetHashDef(hashAlg);
266         HASH_START(hashState);
267         retVal = hashState->def->digestSize;
268     }
269 #undef HASH_START
270     hashState->type = HASH_STATE_HASH;
271     return retVal;
272 }
```

10.2.13.5.3 CryptDigestUpdate()

Add data to a hash or HMAC, SMAC stack.

```
273 void
274 CryptDigestUpdate(
275     PHASH_STATE      hashState,      // IN: the hash context information
276     UINT32           dataSize,       // IN: the size of data to be added
277     const BYTE      *data            // IN: data to be hashed
278     )
279 {
280     if(hashState->hashAlg != TPM_ALG_NULL)
281     {
282         if((hashState->type == HASH_STATE_HASH)
283            || (hashState->type == HASH_STATE_HMAC))
284             HASH_DATA(hashState, dataSize, (BYTE *)data);
285 #if SMAC_IMPLEMENTED
286         else if(hashState->type == HASH_STATE_SMAC)
287             (hashState->state.smac.smacMethods.data)(&hashState->state.smac.state,
288                                                      dataSize, data);
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
289 #endif // SMAC_IMPLEMENTED
290         else
291             FAIL(FATAL_ERROR_INTERNAL);
292     }
293     return;
294 }
```

10.2.13.5.4 CryptHashEnd()

Complete a hash or HMAC computation. This function will place the smaller of *digestSize* or the size of the digest in *dOut*. The number of bytes in the placed in the buffer is returned. If there is a failure, the returned value is <= 0.

Return Value	Meaning
0	no data returned
0	the number of bytes in the digest or *dOutSize*, whichever is smaller

```
295 LIB_EXPORT UINT16
296 CryptHashEnd(
297     PHASH_STATE      hashState,     // IN: the state of hash stack
298     UINT32           dOutSize,      // IN: size of digest buffer
299     BYTE            *dOut           // OUT: hash digest
300     )
301 {
302     pAssert(hashState->type == HASH_STATE_HASH);
303     return HashEnd(hashState, dOutSize, dOut);
304 }
```

10.2.13.5.5 CryptHashBlock()

Start a hash, hash a single block, update *digest* and return the size of the results.

The *digestSize* parameter can be smaller than the digest. If so, only the more significant bytes are returned.

Return Value	Meaning
0	number of bytes placed in *dOut*

```
305 LIB_EXPORT UINT16
306 CryptHashBlock(
307     TPM_ALG_ID       hashAlg,       // IN: The hash algorithm
308     UINT32           dataSize,      // IN: size of buffer to hash
309     const BYTE      *data,          // IN: the buffer to hash
310     UINT32           dOutSize,      // IN: size of the digest buffer
311     BYTE            *dOut           // OUT: digest buffer
312     )
313 {
314     HASH_STATE          state;
315     CryptHashStart(&state, hashAlg);
316     CryptDigestUpdate(&state, dataSize, data);
317     return HashEnd(&state, dOutSize, dOut);
318 }
```

10.2.13.5.6 CryptDigestUpdate2B()

This function updates a digest (hash or HMAC) with a TPM2B.

This function can be used for both HMAC and hash functions so the *digestState* is void so that either state type can be passed.

```
319     LIB_EXPORT void
320     CryptDigestUpdate2B(
321         PHASH_STATE      state,          // IN: the digest state
322         const TPM2B     *bIn             // IN: 2B containing the data
323         )
324     {
325         // Only compute the digest if a pointer to the 2B is provided.
326         // In CryptDigestUpdate(), if size is zero or buffer is NULL, then no change
327         // to the digest occurs. This function should not provide a buffer if bIn is
328         // not provided.
329         pAssert(bIn != NULL);
330         CryptDigestUpdate(state, bIn->size, bIn->buffer);
331         return;
332     }
```

10.2.13.5.7 CryptHashEnd2B()

This function is the same as CryptCompleteHash() but the digest is placed in a TPM2B. This is the most common use and this is provided for specification clarity. *digest.size* should be set to indicate the number of bytes to place in the buffer

Return Value	Meaning
>=0	the number of bytes placed in *digest.buffer*

```
333     LIB_EXPORT UINT16
334     CryptHashEnd2B(
335         PHASH_STATE      state,          // IN: the hash state
336         P2B              digest          // IN: the size of the buffer Out: requested
337                                          //     number of bytes
338         )
339     {
340         return CryptHashEnd(state, digest->size, digest->buffer);
341     }
```

10.2.13.5.8 CryptDigestUpdateInt()

This function is used to include an integer value to a hash stack. The function marshals the integer into its canonical form before calling CryptDigestUpdate().

```
342     LIB_EXPORT void
343     CryptDigestUpdateInt(
344         void            *state,          // IN: the state of hash stack
345         UINT32           intSize,        // IN: the size of 'intValue' in bytes
346         UINT64           intValue        // IN: integer value to be hashed
347         )
348     {
349     #if LITTLE_ENDIAN_TPM
350         intValue = REVERSE_ENDIAN_64(intValue);
351     #endif
352         CryptDigestUpdate(state, intSize, &((BYTE *)&intValue)[8 - intSize]);
353     }
```

10.2.13.6 HMAC Functions

10.2.13.6.1 CryptHmacStart()

This function is used to start an HMAC using a temp hash context. The function does the initialization of the hash with the HMAC key XOR *iPad* and updates the HMAC key XOR *oPad*.

The function returns the number of bytes in a digest produced by *hashAlg*.

Return Value	Meaning
0	number of bytes in digest produced by *hashAlg* (may be zero)

```
354  LIB_EXPORT UINT16
355  CryptHmacStart(
356      PHMAC_STATE      state,          // IN/OUT: the state buffer
357      TPM_ALG_ID       hashAlg,        // IN: the algorithm to use
358      UINT16           keySize,        // IN: the size of the HMAC key
359      const BYTE      *key             // IN: the HMAC key
360      )
361  {
362      PHASH_DEF                hashDef;
363      BYTE *                   pb;
364      UINT32                   i;
365  //
366      hashDef = CryptGetHashDef(hashAlg);
367      if(hashDef->digestSize != 0)
368      {
369      // If the HMAC key is larger than the hash block size, it has to be reduced
370      // to fit. The reduction is a digest of the hashKey.
371          if(keySize > hashDef->blockSize)
372          {
373              // if the key is too big, reduce it to a digest of itself
374              state->hmacKey.t.size = CryptHashBlock(hashAlg, keySize, key,
375                                                     hashDef->digestSize,
376                                                     state->hmacKey.t.buffer);
377          }
378          else
379          {
380              memcpy(state->hmacKey.t.buffer, key, keySize);
381              state->hmacKey.t.size = keySize;
382          }
383          // XOR the key with iPad (0x36)
384          pb = state->hmacKey.t.buffer;
385          for(i = state->hmacKey.t.size; i > 0; i--)
386              *pb++ ^= 0x36;
387
388          // if the keySize is smaller than a block, fill the rest with 0x36
389          for(i = hashDef->blockSize - state->hmacKey.t.size; i > 0; i--)
390              *pb++ = 0x36;
391
392          // Increase the oPadSize to a full block
393          state->hmacKey.t.size = hashDef->blockSize;
394
395          // Start a new hash with the HMAC key
396          // This will go in the caller's state structure and may be a sequence or not
397          CryptHashStart((PHASH_STATE)state, hashAlg);
398          CryptDigestUpdate((PHASH_STATE)state, state->hmacKey.t.size,
399                            state->hmacKey.t.buffer);
400          // XOR the key block with 0x5c ^ 0x36
401          for(pb = state->hmacKey.t.buffer, i = hashDef->blockSize; i > 0; i--)
402              *pb++ ^= (0x5c ^ 0x36);
403      }
404      // Set the hash algorithm
```

```
405     state->hashState.hashAlg = hashAlg;
406     // Set the hash state type
407     state->hashState.type = HASH_STATE_HMAC;
408
409     return hashDef->digestSize;
410 }
```

10.2.13.6.2 CryptHmacEnd()

This function is called to complete an HMAC. It will finish the current digest, and start a new digest. It will then add the *oPadKey* and the completed digest and return the results in *dOut*. It will not return more than *dOutSize* bytes.

Return Value	Meaning
0	number of bytes in *dOut* (may be zero)

```
411 LIB_EXPORT UINT16
412 CryptHmacEnd(
413     PHMAC_STATE      state,          // IN: the hash state buffer
414     UINT32           dOutSize,       // IN: size of digest buffer
415     BYTE            *dOut            // OUT: hash digest
416     )
417 {
418     BYTE                  temp[MAX_DIGEST_SIZE];
419     PHASH_STATE           hState = (PHASH_STATE)&state->hashState;
420
421 #if SMAC_IMPLEMENTED
422     if(hState->type == HASH_STATE_SMAC)
423         return (state->hashState.state.smac.smacMethods.end)
424                     (&state->hashState.state.smac.state,
425                      dOutSize,
426                      dOut);
427 #endif
428     pAssert(hState->type == HASH_STATE_HMAC);
429     hState->def = CryptGetHashDef(hState->hashAlg);
430     // Change the state type for completion processing
431     hState->type = HASH_STATE_HASH;
432     if(hState->hashAlg == TPM_ALG_NULL)
433         dOutSize = 0;
434     else
435     {
436
437     // Complete the current hash
438         HashEnd(hState, hState->def->digestSize, temp);
439         // Do another hash starting with the oPad
440         CryptHashStart(hState, hState->hashAlg);
441         CryptDigestUpdate(hState, state->hmacKey.t.size, state->hmacKey.t.buffer);
442         CryptDigestUpdate(hState, hState->def->digestSize, temp);
443     }
444     return HashEnd(hState, dOutSize, dOut);
445 }
```

10.2.13.6.3 CryptHmacStart2B()

This function starts an HMAC and returns the size of the digest that will be produced.

This function is provided to support the most common use of starting an HMAC with a TPM2B key.

The caller must provide a block of memory in which the hash sequence state is kept. The caller should not alter the contents of this buffer until the hash sequence is completed or abandoned.

Return Value	Meaning
0	the digest size of the algorithm
0	the *hashAlg* was TPM_ALG_NULL

```
446  LIB_EXPORT UINT16
447  CryptHmacStart2B(
448      PHMAC_STATE      hmacState,      // OUT: the state of HMAC stack. It will be used
449                                       //     in HMAC update and completion
450      TPMI_ALG_HASH    hashAlg,        // IN: hash algorithm
451      P2B              key             // IN: HMAC key
452      )
453  {
454      return CryptHmacStart(hmacState, hashAlg, key->size, key->buffer);
455  }
```

10.2.13.6.4 CryptHmacEnd2B()

This function is the same as CryptHmacEnd() but the HMAC result is returned in a TPM2B which is the most common use.

Return Value	Meaning
>=0	the number of bytes placed in *digest*

```
456  LIB_EXPORT UINT16
457  CryptHmacEnd2B(
458      PHMAC_STATE      hmacState,      // IN: the state of HMAC stack
459      P2B              digest          // OUT: HMAC
460      )
461  {
462      return CryptHmacEnd(hmacState, digest->size, digest->buffer);
463  }
```

10.2.13.7 Mask and Key Generation Functions

10.2.13.7.1 CryptMGF1()

This function performs MGF1 using the selected hash. MGF1 is T(n) = T(n-1) || H(seed || counter). This function returns the length of the mask produced which could be zero if the digest algorithm is not supported

Return Value	Meaning
0	hash algorithm was TPM_ALG_NULL
0	should be the same as *mSize*

```
464  LIB_EXPORT UINT16
465  CryptMGF1(
466      UINT32           mSize,          // IN: length of the mask to be produced
467      BYTE            *mask,           // OUT: buffer to receive the mask
468      TPM_ALG_ID       hashAlg,        // IN: hash to use
469      UINT32           seedSize,       // IN: size of the seed
470      BYTE            *seed            // IN: seed size
471      )
472  {
473      HASH_STATE           hashState;
474      PHASH_DEF            hDef = CryptGetHashDef(hashAlg);
475      UINT32               remaining;
```

```
476     UINT32               counter = 0;
477     BYTE                 swappedCounter[4];
478
479     // If there is no digest to compute return
480     if((hashAlg == TPM_ALG_NULL) || (mSize == 0))
481         return 0;
482
483     for(remaining = mSize; ; remaining -= hDef->digestSize)
484     {
485         // Because the system may be either Endian...
486         UINT32_TO_BYTE_ARRAY(counter, swappedCounter);
487
488         // Start the hash and include the seed and counter
489         CryptHashStart(&hashState, hashAlg);
490         CryptDigestUpdate(&hashState, seedSize, seed);
491         CryptDigestUpdate(&hashState, 4, swappedCounter);
492
493         // Handling the completion depends on how much space remains in the mask
494         // buffer. If it can hold the entire digest, put it there. If not
495         // put the digest in a temp buffer and only copy the amount that
496         // will fit into the mask buffer.
497         HashEnd(&hashState, remaining, mask);
498         if(remaining <= hDef->digestSize)
499             break;
500         mask = &mask[hDef->digestSize];
501         counter++;
502     }
503     return (UINT16)mSize;
504 }
```

10.2.13.7.2 CryptKDFa()

This function performs the key generation according to Part 1 of the TPM specification.

This function returns the number of bytes generated which may be zero.

The *key* and *keyStream* pointers are not allowed to be NULL. The other pointer values may be NULL. The value of *sizeInBits* must be no larger than (2^18)-1 = 256K bits (32385 bytes).

The *once* parameter is set to allow incremental generation of a large value. If this flag is TRUE, *sizeInBits* will be used in the HMAC computation but only one iteration of the KDF is performed. This would be used for XOR obfuscation so that the mask value can be generated in digest-sized chunks rather than having to be generated all at once in an arbitrarily large buffer and then XORed into the result. If *once* is TRUE, then *sizeInBits* must be a multiple of 8.

Any error in the processing of this command is considered fatal.

Return Value	Meaning
0	hash algorithm is not supported or is TPM_ALG_NULL
0	the number of bytes in the *keyStream* buffer

```
505 LIB_EXPORT UINT16
506 CryptKDFa(
507     TPM_ALG_ID       hashAlg,        // IN: hash algorithm used in HMAC
508     const TPM2B     *key,            // IN: HMAC key
509     const TPM2B     *label,          // IN: a label for the KDF
510     const TPM2B     *contextU,       // IN: context U
511     const TPM2B     *contextV,       // IN: context V
512     UINT32           sizeInBits,     // IN: size of generated key in bits
513     BYTE            *keyStream,      // OUT: key buffer
514     UINT32          *counterInOut,   // IN/OUT: caller may provide the iteration
515                                      //     counter for incremental operations to
```

```
516                                     //     avoid large intermediate buffers.
517     UINT16          blocks          // IN: If non-zero, this is the maximum number
518                                     //     of blocks to be returned, regardless
519                                     //     of sizeInBits
520     )
521 {
522     UINT32                   counter = 0;        // counter value

```
582             CryptHmacEnd(&hState, bytes, stream);
583             stream = &stream[digestSize];
584         }
585         // Masking in the KDF is disabled. If the calling function wants something
586         // less than even number of bytes, then the caller should do the masking
587         // because there is no universal way to do it here
588         if(counterInOut != NULL)
589             *counterInOut = counter;
590         return generated;
591     }
```

10.2.13.7.3 CryptKDFe()

This function implements KDFe() as defined in TPM specification part 1.

This function returns the number of bytes generated which may be zero.

The *Z* and *keyStream* pointers are not allowed to be NULL. The other pointer values may be NULL. The value of *sizeInBits* must be no larger than (2^18)-1 = 256K bits (32385 bytes). Any error in the processing of this command is considered fatal.

Return Value	Meaning
0	hash algorithm is not supported or is TPM_ALG_NULL
0	the number of bytes in the *keyStream* buffer

```
592     LIB_EXPORT UINT16
593     CryptKDFe(
594         TPM_ALG_ID       hashAlg,       // IN: hash algorithm used in HMAC
595         TPM2B           *Z,             // IN: Z
596         const TPM2B     *label,         // IN: a label value for the KDF
597         TPM2B           *partyUInfo,    // IN: PartyUInfo
598         TPM2B           *partyVInfo,    // IN: PartyVInfo

42     return next;
43 }
```

10.2.14.1.1 IsPrimeInt()

This will do a test of a word of up to 32-bits in size.

```
44 BOOL
45 IsPrimeInt(
46     uint32_t            n
47     )
48 {
49     uint32_t            i;
50     uint32_t            stop;
51     if(n < 3 || ((n & 1) == 0))
```

```
52              return (n == 2);
53          if(n <= s_LastPrimeInTable)
54          {
55              n >>= 1;
56              return ((s_PrimeTable[n >> 3] >> (n & 7)) & 1);
57          }
58          // Need to search
59          stop = Root2(n) >> 1;
60          // starting at 1 is equivalent to staring at  (1 << 1) + 1 = 3
61          for(i = 1; i < stop; i++)
62          {
63              if((s_PrimeTable[i >> 3] >> (i & 7)) & 1)
64                  // see if this prime evenly divides the number
65                  if((n % ((i << 1) + 1)) == 0)
66                      return FALSE;
67          }
68          return TRUE;
69      }
```

10.2.14.1.2 BnIsProbablyPrime()

This function is used when the key sieve is not implemented. This function Will try to eliminate some of the obvious things before going on to perform MillerRabin() as a final verification of primeness.

```
70      BOOL
71      BnIsProbablyPrime(
72          bigNum          prime,           // IN:
73          RAND_STATE      *rand            // IN: the random state just
74                                           //     in case Miller-Rabin is required
75          )
76      {
77      #if RADIX_BITS > 32
78          if(BnUnsignedCmpWord(prime, UINT32_MAX) <= 0)
79      #else
80          if(BnGetSize(prime) == 1)
81      #endif
82              return IsPrimeInt((uint32_t)prime->d[0]);
83
84          if(BnIsEven(prime))
85              return FALSE;
86          if(BnUnsignedCmpWord(prime, s_LastPrimeInTable) <= 0)
87          {
88              crypt_uword_t       temp = prime->d[0] >> 1;
89              return ((s_PrimeTable[temp >> 3] >> (temp & 7)) & 1);
90          }
91          {
92              BN_VAR(n, LARGEST_NUMBER_BITS);
93              BnGcd(n, prime, s_CompositeOfSmallPrimes);
94              if(!BnEqualWord(n, 1))
95                  return FALSE;
96          }
97          return MillerRabin(prime, rand);
98      }
```

10.2.14.1.3 MillerRabinRounds()

Function returns the number of Miller-Rabin rounds necessary to give an error probability equal to the security strength of the prime. These values are from FIPS 186-3.

```
99      UINT32
100     MillerRabinRounds(
101         UINT32          bits            // IN: Number of bits in the RSA prime
```

 Copyright © TCG 2006-2020

```
102         )
103     {
104         if(bits < 511) return 8;     // don't really expect this
105         if(bits < 1536) return 5;    // for 512 and 1K primes
106         return 4;                    // for 3K public modulus and greater
107     }
```

10.2.14.1.4 MillerRabin()

This function performs a Miller-Rabin test from FIPS 186-3. It does *iterations* trials on the number. In all likelihood, if the number is not prime, the first test fails.

Return Value	Meaning
TRUE(1)	probably prime
FALSE(0)	composite

```
108     BOOL
109     MillerRabin(
110         bigNum          bnW,
111         RAND_STATE     *rand
112         )
113     {
114         BN_MAX(bnWm1);

189      }
190      #if ALG_RSA
```

10.2.14.1.5 RsaCheckPrime()

This will check to see if a number is prime and appropriate for an RSA prime.

This has different functionality based on whether we are using key sieving or not. If not, the number checked to see if it is divisible by the public exponent, then the number is adjusted either up or down in order to make it a better candidate. It is then checked for being probably prime.

If sieving is used, the number is used to root a sieving process.

```
191      TPM_RC
192      RsaCheckPrime(
193          bigNum           prime,
194          UINT32           exponent,
195          RAND_STATE      *rand
196          )
197      {
198      #if !RSA_KEY_SIEVE
199          TPM_RC          retVal = TPM_RC_SUCCESS;
200          UINT32          modE = BnModWord(prime, exponent);
201
202          NOT_REFERENCED(rand);
203
204          if(modE == 0)
205              // evenly divisible so add two keeping the number odd
206              BnAddWord(prime, prime, 2);
```

```
207     // want 0 != (p - 1) mod e
208     // which is 1 != p mod e
209     else if(modE == 1)
210         // subtract 2 keeping number odd and insuring that
211         // 0 != (p - 1) mod e
212         BnSubWord(prime, prime, 2);

```

10.2.14.1.6 AdjustPrimeCandiate()

For this math, we assume that the RSA numbers are fixed-point numbers with the decimal point to the **left** of the most significant bit. This approach helps make it clear what is happening with the MSb of the values. The two RSA primes have to be large enough so that their product will be a number with the necessary number of significant bits. For example, we want to be able to multiply two 1024-bit numbers to produce a number with 2048 significant bits. If we accept any 1024-bit prime that has its MSb set, then it is possible to produce a product that does not have the MSb SET. For example, if we use tiny keys of 16 bits and have two 8-bit *primes* of 0x80, then the public key would be 0x4000 which is only 15-bits. So, what we need to do is made sure that each of the primes is large enough so that the product of the primes is twice as large as each prime. A little arithmetic will show that the only way to do this is to make sure that each of the primes is no less than root(2)/2. That's what this functions does. This function adjusts the candidate prime so that it is odd and >= root(2)/2. This allows the product of these two numbers to be .5, which, in fixed point notation means that the most significant bit is 1. For this routine, the root(2)/2 (0.7071067811865475) approximated with *0xB505* which is, in fixed point, 0.7071075439453125 or an error of 0.000108%. Just setting the upper two bits would give a value > 0.75 which is an error of > 6%. Given the amount of time all the other computations take, reducing the error is not much of a cost, but it isn't totally required either.

This function can be replaced with a function that just sets the two most significant bits of each prime candidate without introducing any computational issues.

```
222 LIB_EXPORT void
223 RsaAdjustPrimeCandidate(
224     bigNum          prime
225     )
226 {
227     UINT32          msw;
228     UINT32          adjusted;
229
230     // If the radix is 32, the compiler should turn this into a simple assignment
231     msw = prime->d[prime->size - 1] >> ((RADIX_BITS == 64) ? 32 : 0);
232     // Multiplying 0xff...f by 0x4AFB gives 0xff..f - 0xB5050...0
233     adjusted = (msw >> 16) * 0x4AFB;
234     adjusted += ((msw & 0xFFFF) * 0x4AFB) >> 16;
235     adjusted += 0xB5050000UL;
236 #if RADIX_BITS == 64
237     // Save the low-order 32 bits
238     prime->d[prime->size - 1] &= 0xFFFFFFFFUL;
239     // replace the upper 32-bits
240     prime->d[prime->size -1] |= ((crypt_uword_t)adjusted << 32);
241 #else
242     prime->d[prime->size - 1] = (crypt_uword_t)adjusted;

10.2.15.1.2 BitsInArry()

This function counts the number of bits set in an array of bytes.

```
123     static int
124     BitsInArray(
125         const unsigned char     *a,             // IN: A pointer to an array of bytes
126         unsigned int             aSize          // IN: the number of bytes to sum
127         )
128     {
129         int     j = 0;
130         for(; aSize; a++, aSize--)
131             j += BitsInByte(*a);
132         return j;
133     }
```

10.2.15.1.3 FindNthSetBit()

This function finds the nth SET bit in a bit array. The *n* parameter is between 1 and the number of bits in the array (always a multiple of 8). If called when the array does not have n bits set, it will return -1

Return Value	Meaning
<0	no bit is set or no bit with the requested number is set
>=0	the number of the bit in the array that is the nth set

```
134     LIB_EXPORT int
135     FindNthSetBit(
136         const UINT16     aSize,         // IN: the size of the array to check

260                 r = composite % next;
261             // these computations deal with the fact that we have picked a field-sized
262             // range that is aligned to a 105 count boundary. The problem is, this field
263             // only contains odd numbers. If we take our prime guess and walk through all
264             // the numbers using that prime as the 'stride', then every other 'stride' is
265             // going to be an even number. So, we are actually counting by 2 * the stride
266             // We want the count to start on an odd number at the start of our field. That
267             // is, we want to assume that we have counted up to the edge of the field by
268             // the 'stride' and now we are going to start flipping bits in the field as we
269             // continue to count up by 'stride'. If we take the base of our field and
270             // divide by the stride, we find out how much we find out how short the last
271             // count was from reaching the edge of the bit field. Say we get a quotient of
272             // 3 and remainder of 1. This means that after 3 strides, we are 1 short of
273             // the start of the field and the next stride will either land within the
274             // field or step completely over it. The confounding factor is that our field
275             // only contains odd numbers and our stride is actually 2 * stride. If the
276             // quoitent is even, then that means that when we add 2 * stride, we are going
277             // to hit another even number. So, we have to know if we need to back off
278             // by 1 stride before we start couting by 2 * stride.
279             // We can tell from the remainder whether we are on an even or odd
280             // stride when we hit the beginning of the table. If we are on an odd stride
281             // (r & 1), we would start half a stride in (next - r)/2. If we are on an
282             // even stride, we need 0.5 strides (next - r/2) because the table only has
283             // odd numbers. If the remainder happens to be zero, then the start of the
284             // table is on stride so no adjustment is necessary.

10.2.15.1.4 PrimeSelectWithSieve()

This function will sieve the field around the input prime candidate. If the sieve field is not empty, one of the one bits in the field is chosen for testing with Miller-Rabin. If the value is prime, *pnP* is updated with this value and the function returns success. If this value is not prime, another pseudo-random candidate is chosen and tested. This process repeats until all values in the field have been checked. If all bits in the field have been checked and none is prime, the function returns FALSE and a new random value needs to be chosen.

Error Returns	Meaning
TPM_RC_FAILURE	TPM in failure mode, probably due to entropy source
TPM_RC_SUCCESS	candidate is probably prime
TPM_RC_NO_RESULT	candidate is not prime and couldn't find and alternative in the field

```
322 LIB_EXPORT TPM_RC

10.2.16 CryptRand.c

10.2.16.1 Introduction

This file implements a DRBG with a behavior according to SP800-90A using a block cypher. This is also compliant to ISO/IEC 18031:2011(E) C.3.2.

A state structure is created for use by TPM.lib and functions within the CryptoEngine() my use their own state structures when they need to have deterministic values.

A debug mode is available that allows the random numbers generated for TPM.lib to be repeated during runs of the simulator. The switch for it is in TpmBuildSwitches.h. It is USE_DEBUG_RNG.

This is the implementation layer of CTR DRGB mechanism as defined in SP800-90A and the functions are organized as closely as practical to the organization in SP800-90A. It is intended to be compiled as a separate module that is linked with a secure application so that both reside inside the same boundary [SP 800-90A 8.5]. The secure application in particular manages the accesses protected storage for the state of the DRBG instantiations, and supplies the implementation functions here with a valid pointer to the working state of the given instantiations (as a DRBG_STATE structure).

This DRBG mechanism implementation does not support prediction resistance. Thus *prediction_resistance_flag* is omitted from Instantiate_function(), Reseed_function(), Generate_function() argument lists [SP 800-90A 9.1, 9.2, 9.3], as well as from the working state data structure DRBG_STATE [SP 800-90A 9.1].

This DRBG mechanism implementation always uses the highest security strength of available in the block ciphers. Thus *requested_security_strength* parameter is omitted from Instantiate_function() and Generate_function() argument lists [SP 800-90A 9.1, 9.2, 9.3], as well as from the working state data structure DRBG_STATE [SP 800-90A 9.1].

Internal functions (ones without Crypt prefix) expect validated arguments and therefore use assertions instead of runtime parameter checks and mostly return void instead of a status value.

10
11  //** Derivation Functions
12  //*** Description
13  // The functions in this section are used to reduce the personalization input values
14  // to make them usable as input for reseeding and instantiation. The overall
15  // behavior is intended to produce the same results as described in SP800-90A,
16  // section 10.4.2 "Derivation Function Using a Block Cipher Algorithm
17  // (Block_Cipher_df)." The code is broken into several subroutines to deal with the
18  // fact that the data used for personalization may come in several separate blocks
19  // such as a Template hash and a proof value and a primary seed.
20
21  //*** Derivation Function Defines and Structures
22
23  #define     DF_COUNT (DRBG_KEY_SIZE_WORDS / DRBG_IV_SIZE_WORDS + 1)
24  #if DRBG_KEY_SIZE_BITS != 128 && DRBG_KEY_SIZE_BITS != 256
25  #   error "CryptRand.c only written for AES with 128- or 256-bit keys."
26  #endif
```

```
27  typedef struct
28  {
29      DRBG_KEY_SCHEDULE   keySchedule;
30      DRBG_IV             iv[DF_COUNT];
31      DRBG_IV             out1;
32      DRBG_IV             buf;
33      int                 contents;
34  } DF_STATE, *PDF_STATE;
```

10.2.16.1.1 DfCompute()

This function does the incremental update of the derivation function state. It encrypts the *iv* value and XOR's the results into each of the blocks of the output. This is equivalent to processing all of input data for each output block.

```
35  static void
36  DfCompute(
37      PDF_STATE        dfState
38      )
39  {
40      int              i;
41      int              iv;
42      crypt_uword_t   *pIv;
43      crypt_uword_t    temp[DRBG_IV_SIZE_WORDS] = {0};
44  //
45      for(iv = 0; iv < DF_COUNT; iv++)
46      {
47          pIv = (crypt_uword_t *)&dfState->iv[iv].words[0];
48          for(i = 0; i < DRBG_IV_SIZE_WORDS; i++)
49          {
50              temp[i] ^= pIv[i] ^ dfState->buf.words[i];
51          }
52          DRBG_ENCRYPT(&dfState->keySchedule, &temp, pIv);
53      }
54      for(i = 0; i < DRBG_IV_SIZE_WORDS; i++)
55          dfState->buf.words[i] = 0;
56      dfState->contents = 0;
57  }
```

10.2.16.1.2 DfStart()

This initializes the output blocks with an encrypted counter value and initializes the key schedule.

```
58  static void
59  DfStart(
60      PDF_STATE        dfState,
61      uint32_t         inputLength
62      )
63  {
64      BYTE            init[8];
65      int             i;
66      UINT32          drbgSeedSize = sizeof(DRBG_SEED);
67
68      const BYTE dfKey[DRBG_KEY_SIZE_BYTES] = {
69          0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07,
70          0x08, 0x09, 0x0a, 0x0b, 0x0c, 0x0d, 0x0e, 0x0f
71      #if DRBG_KEY_SIZE_BYTES > 16
72          ,0x10, 0x11, 0x12, 0x13, 0x14, 0x15, 0x16, 0x17,
73          0x18, 0x19, 0x1a, 0x1b, 0x1c, 0x1d, 0x1e, 0x1f
74      #endif
75      };
76      memset(dfState, 0, sizeof(DF_STATE));
```

 Copyright © TCG 2006-2020

```
77      DRBG_ENCRYPT_SETUP(&dfKey[0], DRBG_KEY_SIZE_BITS, &dfState->keySchedule);
78      // Create the first chaining values
79      for(i = 0; i < DF_COUNT; i++)
80          ((BYTE *)&dfState->iv[i])[3] = (BYTE)i;
81      DfCompute(dfState);
82      // initialize the first 64 bits of the IV in a way that doesn't depend
83      // on the size of the words used.
84      UINT32_TO_BYTE_ARRAY(inputLength, init);
85      UINT32_TO_BYTE_ARRAY(drbgSeedSize, &init[4]);
86      memcpy(&dfState->iv[0], init, 8);
87      dfState->contents = 4;
88  }
```

10.2.16.1.3 DfUpdate()

This updates the state with the input data. A byte at a time is moved into the state buffer until it is full and then that block is encrypted by DfCompute().

```
89  static void
90  DfUpdate(
91      PDF_STATE        dfState,
92      int              size,
93      const BYTE      *data
94      )
95  {
96      while(size > 0)
97      {
98          int         toFill = DRBG_IV_SIZE_BYTES - dfState->contents;
99          if(size < toFill)
100             toFill = size;
101         // Copy as many bytes as there are or until the state buffer is full
102         memcpy(&dfState->buf.bytes[dfState->contents], data, toFill);
103         // Reduce the size left by the amount copied
104         size -= toFill;
105         // Advance the data pointer by the amount copied
106         data += toFill;
107         // increase the buffer contents count by the amount copied
108         dfState->contents += toFill;
109         pAssert(dfState->contents <= DRBG_IV_SIZE_BYTES);
110         // If we have a full buffer, do a computation pass.
111         if(dfState->contents == DRBG_IV_SIZE_BYTES)
112             DfCompute(dfState);
113     }
114 }
```

10.2.16.1.4 DfEnd()

This function is called to get the result of the derivation function computation. If the buffer is not full, it is padded with zeros. The output buffer is structured to be the same as a DRBG_SEED value so that the function can return a pointer to the DRBG_SEED value in the DF_STATE structure.

```
115 static DRBG_SEED *
116 DfEnd(
117     PDF_STATE        dfState
118     )
119 {
120     // Since DfCompute is always called when a buffer is full, there is always
121     // space in the buffer for the terminator
122     dfState->buf.bytes[dfState->contents++] = 0x80;
123     // If the buffer is not full, pad with zeros
124     while(dfState->contents < DRBG_IV_SIZE_BYTES)
125         dfState->buf.bytes[dfState->contents++] = 0;
```

```
126     // Do a final state update
127     DfCompute(dfState);
128     return (DRBG_SEED *)&dfState->iv;
129 }
```

10.2.16.1.5 DfBuffer()

Function to take an input buffer and do the derivation function to produce a DRBG_SEED value that can be used in DRBG_Reseed();

```
130 static DRBG_SEED *
131 DfBuffer(
132     DRBG_SEED       *output,        // OUT: receives the result
133     int              size,          // IN: size of the buffer to add
134     BYTE            *buf            // IN: address of the buffer
135     )
136 {
137     DF_STATE        dfState;
138     if(size == 0 || buf == NULL)
139         return NULL;
140     // Initialize the derivation function
141     DfStart(&dfState, size);
142     DfUpdate(&dfState, size, buf);
143     DfEnd(&dfState);
144     memcpy(output, &dfState.iv[0], sizeof(DRBG_SEED));
145     return output;
146 }
```

10.2.16.1.6 DRBG_GetEntropy()

Even though this implementation never fails, it may get blocked indefinitely long in the call to get entropy from the platform (DRBG_GetEntropy32()). This function is only used during instantiation of the DRBG for manufacturing and on each start-up after an non-orderly shutdown.

Return Value	Meaning
TRUE(1)	requested entropy returned
FALSE(0)	entropy Failure

```
147 BOOL
148 DRBG_GetEntropy(
149     UINT32           requiredEntropy,   // IN: requested number of bytes of full
150                                         //     entropy
151     BYTE            *entropy            // OUT: buffer to return collected entropy
152     )
153 {
154 #if !USE_DEBUG_RNG
155
156     UINT32      obtainedEntropy;
157     INT32       returnedEntropy;
158
159 // If in debug mode, always use the self-test values for initialization
160     if(IsSelfTest())
161     {
162 #endif
163         // If doing simulated DRBG, then check to see if the
164         // entropyFailure condition is being tested
165         if(!IsEntropyBad())
166         {
167             // In self-test, the caller should be asking for exactly the seed
168             // size of entropy.
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
169                 pAssert(requiredEntropy == sizeof(DRBG_NistTestVector_Entropy));
170                 memcpy(entropy, DRBG_NistTestVector_Entropy,
171                        sizeof(DRBG_NistTestVector_Entropy));
172             }
173     #if !USE_DEBUG_RNG
174         }
175         else if(!IsEntropyBad())
176         {
177             // Collect entropy
178             // Note: In debug mode, the only "entropy" value ever returned
179             // is the value of the self-test vector.
180             for(returnedEntropy = 1, obtainedEntropy = 0;
181                 obtainedEntropy < requiredEntropy && !IsEntropyBad();
182                 obtainedEntropy += returnedEntropy)
183             {
184                 returnedEntropy = _plat__GetEntropy(&entropy[obtainedEntropy],
185                                                     requiredEntropy - obtainedEntropy);
186                 if(returnedEntropy <= 0)
187                     SetEntropyBad();
188             }
189         }
190     #endif
191         return !IsEntropyBad();
192     }
```

10.2.16.1.7 IncrementIv()

This function increments the IV value by 1. It is used by EncryptDRBG().

```
193     void
194     IncrementIv(
195         DRBG_IV         *iv
196         )
197     {
198         BYTE      *ivP = ((BYTE *)iv) + DRBG_IV_SIZE_BYTES;
199         while((--ivP >= (BYTE *)iv) && ((*ivP = ((*ivP + 1) & 0xFF)) == 0));
200     }
```

10.2.16.1.8 EncryptDRBG()

This does the encryption operation for the DRBG. It will encrypt the input state counter (IV) using the state key. Into the output buffer for as many times as it takes to generate the required number of bytes.

```
201     static BOOL
202     EncryptDRBG(
203         BYTE                 *dOut,
204         UINT32                dOutBytes,
205         DRBG_KEY_SCHEDULE    *keySchedule,
206         DRBG_IV              *iv,
207         UINT32               *lastValue      // Points to the last output value
208         )
209     {
210     #if FIPS_COMPLIANT
211     // For FIPS compliance, the DRBG has to do a continuous self-test to make sure that
212     // no two consecutive values are the same. This overhead is not incurred if the TPM
213     // is not required to be FIPS compliant
214     //
215         UINT32           temp[DRBG_IV_SIZE_BYTES / sizeof(UINT32)];
216         int              i;
217         BYTE            *p;
218
219         for(; dOutBytes > 0;)
220         {
```

```
221             // Increment the IV before each encryption (this is what makes this
222             // different from normal counter-mode encryption
223             IncrementIv(iv);
224             DRBG_ENCRYPT(keySchedule, iv, temp);
225     // Expect a 16 byte block
226     #if DRBG_IV_SIZE_BITS != 128
227     #error  "Unsuppored IV size in DRBG"
228     #endif
229             if((lastValue[0] == temp[0])
230                 && (lastValue[1] == temp[1])
231                 && (lastValue[2] == temp[2])
232                 && (lastValue[3] == temp[3])
233                 )
234             {
235                 LOG_FAILURE(FATAL_ERROR_ENTROPY);
236                 return FALSE;
237             }
238             lastValue[0] = temp[0];
239             lastValue[1] = temp[1];
240             lastValue[2] = temp[2];
241             lastValue[3] = temp[3];
242             i = MIN(dOutBytes, DRBG_IV_SIZE_BYTES);
243             dOutBytes -= i;
244             for(p = (BYTE *)temp; i > 0; i--)
245                 *dOut++ = *p++;
246         }
247     #else // version without continuous self-test
248         NOT_REFERENCED(lastValue);
249         for(; dOutBytes >= DRBG_IV_SIZE_BYTES;
250         dOut = &dOut[DRBG_IV_SIZE_BYTES], dOutBytes -= DRBG_IV_SIZE_BYTES)
251         {
252             // Increment the IV
253             IncrementIv(iv);
254             DRBG_ENCRYPT(keySchedule, iv, dOut);
255         }
256         // If there is a partial, generate into a block-sized
257         // temp buffer and copy to the output.
258         if(dOutBytes != 0)
259         {
260             BYTE        temp[DRBG_IV_SIZE_BYTES];
261             // Increment the IV
262             IncrementIv(iv);
263             DRBG_ENCRYPT(keySchedule, iv, temp);
264             memcpy(dOut, temp, dOutBytes);
265         }
266     #endif
267         return TRUE;
268     }
```

10.2.16.1.9 DRBG_Update()

This function performs the state update function. According to SP800-90A, a temp value is created by doing CTR mode encryption of *providedData* and replacing the key and IV with these values. The one difference is that, with counter mode, the IV is incremented after each block is encrypted and in this operation, the counter is incremented before each block is encrypted. This function implements an *optimized* version of the algorithm in that it does the update of the *drbgState*->seed in place and then *providedData* is XORed into *drbgState*->seed to complete the encryption of *providedData*. This works because the IV is the last thing that gets encrypted.

```
269     static BOOL
270     DRBG_Update(
271         DRBG_STATE          *drbgState,     // IN:OUT state to update
272         DRBG_KEY_SCHEDULE   *keySchedule,   // IN: the key schedule (optional)
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
273     DRBG_SEED           *providedData   // IN: additional data
274     )
275 {
276     UINT32               i;
277     BYTE                *temp = (BYTE *)&drbgState->seed;
278     DRBG_KEY            *key = pDRBG_KEY(&drbgState->seed);
279     DRBG_IV             *iv = pDRBG_IV(&drbgState->seed);
280     DRBG_KEY_SCHEDULE    localKeySchedule;
281 //
282     pAssert(drbgState->magic == DRBG_MAGIC);
283
284     // If an key schedule was not provided, make one
285     if(keySchedule == NULL)
286     {
287         if(DRBG_ENCRYPT_SETUP((BYTE *)key,
288             DRBG_KEY_SIZE_BITS, &localKeySchedule) != 0)
289         {
290             LOG_FAILURE(FATAL_ERROR_INTERNAL);
291             return FALSE;
292         }
293         keySchedule = &localKeySchedule;
294     }
295     // Encrypt the temp value
296
297     EncryptDRBG(temp, sizeof(DRBG_SEED), keySchedule, iv,
298                 drbgState->lastValue);
299     if(providedData != NULL)
300     {
301         BYTE         *pP = (BYTE *)providedData;
302         for(i = DRBG_SEED_SIZE_BYTES; i != 0; i--)
303             *temp++ ^= *pP++;
304     }
305     // Since temp points to the input key and IV, we are done and
306     // don't need to copy the resulting 'temp' to drbgState->seed
307     return TRUE;
308 }
```

10.2.16.1.10 DRBG_Reseed()

This function is used when reseeding of the DRBG is required. If entropy is provided, it is used in lieu of using hardware entropy.

NOTE: the provided entropy must be the required size.

Return Value	Meaning
TRUE(1)	reseed succeeded
FALSE(0)	reseed failed, probably due to the entropy generation

```
309 BOOL
310 DRBG_Reseed(
311     DRBG_STATE          *drbgState,        // IN: the state to update
312     DRBG_SEED           *providedEntropy,  // IN: entropy
313     DRBG_SEED           *additionalData    // IN:
314     )
315 {
316     DRBG_SEED            seed;
317
318     pAssert((drbgState != NULL) && (drbgState->magic == DRBG_MAGIC));
319
320     if(providedEntropy == NULL)
321     {
322         providedEntropy = &seed;
```

 Copyright © TCG 2006-2020

```
323             if(!DRBG_GetEntropy(sizeof(DRBG_SEED), (BYTE *)providedEntropy))
324                 return FALSE;
325         }
326         if(additionalData != NULL)
327         {
328             unsigned int          i;
329
330             // XOR the provided data into the provided entropy
331             for(i = 0; i < sizeof(DRBG_SEED); i++)
332                 ((BYTE *)providedEntropy)[i] ^= ((BYTE *)additionalData)[i];
333         }
334         DRBG_Update(drbgState, NULL, providedEntropy);
335
336         drbgState->reseedCounter = 1;
337
338         return TRUE;
339     }
```

10.2.16.1.11 DRBG_SelfTest()

This is run when the DRBG is instantiated and at startup

Return Value	Meaning
TRUE(1)	test OK
FALSE(0)	test failed

```
340     BOOL
341     DRBG_SelfTest(

10.2.16.2 Public Interface

10.2.16.2.1 Description

The functions in this section are the interface to the RNG. These are the functions that are used by TPM.lib.

10.2.16.2.2 CryptRandomStir()

This function is used to cause a reseed. A DRBG_SEED amount of entropy is collected from the hardware and then additional data is added.

Error Returns	Meaning
TPM_RC_NO_RESULT	failure of the entropy generator

```
404  LIB_EXPORT TPM_RC
405  CryptRandomStir(
406      UINT16           additionalDataSize,
407      BYTE            *additionalData
408      )
409  {
410  #if !USE_DEBUG_RNG
411      DRBG_SEED        tmpBuf;
412      DRBG_SEED        dfResult;
413  //
414      // All reseed with outside data starts with a buffer full of entropy
415      if(!DRBG_GetEntropy(sizeof(tmpBuf), (BYTE *)&tmpBuf))
416          return TPM_RC_NO_RESULT;
417
418      DRBG_Reseed(&drbgDefault, &tmpBuf,
419                  DfBuffer(&dfResult, additionalDataSize, additionalData));
420      drbgDefault.reseedCounter = 1;
```

 Copyright © TCG 2006-2020

```
421
422         return TPM_RC_SUCCESS;
423
424     #else
425         // If doing debug, use the input data as the initial setting for the RNG state
426         // so that the test can be reset at any time.
427         // Note: If this is called with a data size of 0 or less, nothing happens. The
428         // presumption is that, in a debug environment, the caller will have specific
429         // values for initialization, so this check is just a simple way to prevent
430         // inadvertent programming errors from screwing things up. This doesn't use an
431         // pAssert() because the non-debug version of this function will accept these
432         // parameters as meaning that there is no additionalData and only hardware
433         // entropy is used.
434         if((additionalDataSize > 0) && (additionalData != NULL))
435         {
436             memset(drbgDefault.seed.bytes, 0, sizeof(drbgDefault.seed.bytes));
437             memcpy(drbgDefault.seed.bytes, additionalData,
438                    MIN(additionalDataSize, sizeof(drbgDefault.seed.bytes)));
439         }
440         drbgDefault.reseedCounter = 1;
441
442         return TPM_RC_SUCCESS;
443     #endif
444     }
```

10.2.16.2.3 CryptRandomGenerate()

Generate a *randomSize* number or random bytes.

```
445     LIB_EXPORT UINT16
446     CryptRandomGenerate(
447         UINT16           randomSize,
448         BYTE            *buffer
449         )
450     {
451         return DRBG_Generate((RAND_STATE *)&drbgDefault, buffer, randomSize);
452     }
```

10.2.16.2.4 DRBG_InstantiateSeededKdf()

This function is used to instantiate a KDF-based RNG. This is used for derivations. This function always returns TRUE.

```
453     LIB_EXPORT BOOL
454     DRBG_InstantiateSeededKdf(
455         KDF_STATE       *state,          // OUT: buffer to hold the state
456         TPM_ALG_ID       hashAlg,        // IN: hash algorithm
457         TPM_ALG_ID       kdf,            // IN: the KDF to use
458         TPM2B           *seed,           // IN: the seed to use
459         const TPM2B     *label,          // IN: a label for the generation process.
460         TPM2B           *context,        // IN: the context value
461         UINT32           limit           // IN: Maximum number of bits from the KDF
462         )
463     {
464         state->magic = KDF_MAGIC;
465         state->limit = limit;
466         state->seed = seed;
467         state->hash = hashAlg;
468         state->kdf = kdf;
469         state->label = label;
470         state->context = context;
471         state->digestSize = CryptHashGetDigestSize(hashAlg);
472         state->counter = 0;
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
473     state->residual.t.size = 0;
474     return TRUE;
475 }
```

10.2.16.2.5 DRBG_AdditionalData()

Function to reseed the DRBG with additional entropy. This is normally called before computing the protection value of a primary key in the Endorsement hierarchy.

```
476 LIB_EXPORT void
477 DRBG_AdditionalData(
478     DRBG_STATE      *drbgState,     // IN:OUT state to update
479     TPM2B           *additionalData // IN: value to incorporate
480     )
481 {
482     DRBG_SEED        dfResult;
483     if(drbgState->magic == DRBG_MAGIC)
484     {
485         DfBuffer(&dfResult, additionalData->size, additionalData->buffer);
486         DRBG_Reseed(drbgState, &dfResult, NULL);
487     }
488 }
```

10.2.16.2.6 DRBG_InstantiateSeeded()

This function is used to instantiate a random number generator from seed values. The nominal use of this generator is to create sequences of pseudo-random numbers from a seed value.

Error Returns	Meaning
TPM_RC_FAILURE	DRBG self-test failure

```
489 LIB_EXPORT TPM_RC
490 DRBG_InstantiateSeeded(
491     DRBG_STATE      *drbgState,     // IN/OUT: buffer to hold the state
492     const TPM2B     *seed,          // IN: the seed to use
493     const TPM2B     *purpose,       // IN: a label for the generation process.
494     const TPM2B     *name,          // IN: name of the object
495     const TPM2B     *additional     // IN: additional data
496     )
497 {
498     DF_STATE         dfState;
499     int              totalInputSize;
500     // DRBG should have been tested, but...
501     if(!IsDrbgTested() && !DRBG_SelfTest())
502     {
503         LOG_FAILURE(FATAL_ERROR_SELF_TEST);
504         return TPM_RC_FAILURE;
505     }
506     // Initialize the DRBG state
507     memset(drbgState, 0, sizeof(DRBG_STATE));
508     drbgState->magic = DRBG_MAGIC;
509
510     // Size all of the values
511     totalInputSize = (seed != NULL) ? seed->size : 0;
512     totalInputSize += (purpose != NULL) ? purpose->size : 0;
513     totalInputSize += (name != NULL) ? name->size : 0;
514     totalInputSize += (additional != NULL) ? additional->size : 0;
515
516     // Initialize the derivation
517     DfStart(&dfState, totalInputSize);
518
```

 Copyright © TCG 2006-2020

```
519     // Run all the input strings through the derivation function
520     if(seed != NULL)
521         DfUpdate(&dfState, seed->size, seed->buffer);
522     if(purpose != NULL)
523         DfUpdate(&dfState, purpose->size, purpose->buffer);
524     if(name != NULL)
525         DfUpdate(&dfState, name->size, name->buffer);
526     if(additional != NULL)
527         DfUpdate(&dfState, additional->size, additional->buffer);
528
529     // Used the derivation function output as the "entropy" input. This is not
530     // how it is described in SP800-90A but this is the equivalent function
531     DRBG_Reseed(((DRBG_STATE *)drbgState), DfEnd(&dfState), NULL);
532
533     return TPM_RC_SUCCESS;
534 }
```

10.2.16.2.7 CryptRandStartup()

This function is called when TPM_Startup is executed. This function always returns TRUE.

```
535 LIB_EXPORT BOOL
536 CryptRandStartup(
537     void
538     )
539 {
540 #if ! _DRBG_STATE_SAVE
541     // If not saved in NV, re-instantiate on each startup
542     DRBG_Instantiate(&drbgDefault, 0, NULL);
543 #else
544     // If the running state is saved in NV, NV has to be loaded before it can
545     // be updated
546     if(go.drbgState.magic == DRBG_MAGIC)
547         DRBG_Reseed(&go.drbgState, NULL, NULL);
548     else
549         DRBG_Instantiate(&go.drbgState, 0, NULL);
550 #endif
551     return TRUE;
552 }
```

10.2.16.2.7.1 CryptRandInit()

This function is called when _TPM_Init() is being processed.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
553 LIB_EXPORT BOOL
554 CryptRandInit(
555     void
556     )
557 {
558 #if !USE_DEBUG_RNG
559     _plat__GetEntropy(NULL, 0);
560 #endif
561     return DRBG_SelfTest();
562 }
```

10.2.16.2.8 DRBG_Generate()

This function generates a random sequence according SP800-90A. If *random* is not NULL, then *randomSize* bytes of random values are generated. If *random* is NULL or *randomSize* is zero, then the function returns zero without generating any bits or updating the reseed counter. This function returns the number of bytes produced which could be less than the number requested if the request is too large ("too large" is implementation dependent.)

```
563 LIB_EXPORT UINT16
564 DRBG_Generate(
565     RAND_STATE      *state,
566     BYTE            *random,        // OUT: buffer to receive the random values
567     UINT16           randomSize     // IN: the number of bytes to generate
568     )
569 {
570     if(state == NULL)
571         state = (RAND_STATE *)&drbgDefault;
572     if(random == NULL)
573         return 0;
574
575     // If the caller used a KDF state, generate a sequence from the KDF not to
576     // exceed the limit.
577     if(state->kdf.magic == KDF_MAGIC)
578     {
579         KDF_STATE       *kdf = (KDF_STATE *)state;
580         UINT32           counter = (UINT32)kdf->counter;
581         INT32            bytesLeft = randomSize;
582 //
583         // If the number of bytes to be returned would put the generator
584         // over the limit, then return 0
585         if((((kdf->counter * kdf->digestSize) + randomSize) * 8) > kdf->limit)
586             return 0;
587         // Process partial and full blocks until all requested bytes provided
588         while(bytesLeft > 0)
589         {
590             // If there is any residual data in the buffer, copy it to the output
591             // buffer
592             if(kdf->residual.t.size > 0)
593             {
594                 INT32      size;
595 //
```

```
596                 // Don't use more of the residual than will fit or more than are
597                 // available
598                 size = MIN(kdf->residual.t.size, bytesLeft);
599
600                 // Copy some or all of the residual to the output. The residual is
601                 // at the end of the buffer. The residual might be a full buffer.
602                 MemoryCopy(random,
603                            &kdf->residual.t.buffer

```

10.2.16.2.9 DRBG_Instantiate()

This is CTR_DRBG_Instantiate_algorithm() from [SP 800-90A 10.2.1.3.1]. This is called when a the TPM DRBG is to be instantiated. This is called to instantiate a DRBG used by the TPM for normal operations.

Return Value	Meaning
TRUE(1)	instantiation succeeded
FALSE(0)	instantiation failed

```
697 LIB_EXPORT BOOL
698 DRBG_Instantiate(
699     DRBG_STATE      *drbgState,         // OUT: the instantiated value
700     UINT16           pSize,             // IN: Size of personalization string
701     BYTE            *personalization    // IN: The personalization string
702     )
703 {
704     DRBG_SEED        seed;
705     DRBG_SEED        dfResult;
706 //
707     pAssert((pSize == 0) || (pSize <= sizeof(seed)) || (personalization != NULL));
708     // If the DRBG has not been tested, test when doing an instantiation. Since
709     // Instantiation is called during self test, make sure we don't get stuck in a
710     // loop.
711     if(!IsDrbgTested() && !IsSelfTest() && !DRBG_SelfTest())
712         return FALSE;
713     // If doing a self test, DRBG_GetEntropy will return the NIST
```

```
714         // test vector value.
715         if(!DRBG_GetEntropy(sizeof(seed), (BYTE *)&seed))
716             return FALSE;
717         // set everything to zero
718         memset(drbgState, 0, sizeof(DRBG_STATE));
719         drbgState->magic = DRBG_MAGIC;
720
721         // Steps 1, 2, 3, 6, 7 of SP 800-90A 10.2.1.3.1 are exactly what
722         // reseeding does. So, do a reduction on the personalization value (if any)
723         // and do a reseed.
724         DRBG_Reseed(drbgState, &seed, DfBuffer(&dfResult, pSize, personalization));
725
726         return TRUE;
727     }
```

10.2.16.2.10 DRBG_Uninstantiate()

This is Uninstantiate_function() from [SP 800-90A 9.4].

Error Returns	Meaning
TPM_RC_VALUE	not a valid state

```
728     LIB_EXPORT TPM_RC
729     DRBG_Uninstantiate(
730         DRBG_STATE      *drbgState      // IN/OUT: working state to erase
731         )
732     {
733         if((drbgState == NULL) || (drbgState->magic != DRBG_MAGIC))
734             return TPM_RC_VALUE;
735         memset(drbgState, 0, sizeof(DRBG_STATE));
736         return TPM_RC_SUCCESS;
737     }
```

10.2.17 CryptRsa.c

10.2.17.1 Introduction

This file contains implementation of cryptographic primitives for RSA. Vendors may replace the implementation in this file with their own library functions.

10.2.17.2 Includes

Need this define to get the *private* defines for this function

```
1   #define CRYPT_RSA_C
2   #include "Tpm.h"
3   #if ALG_RSA
```

10.2.17.3 Obligatory Initialization Functions

10.2.17.3.1 CryptRsaInit()

Function called at _TPM_Init().

```
4   BOOL
5   CryptRsaInit(
6       void
7       )
8   {
9       return TRUE;
10  }
```

10.2.17.3.2 CryptRsaStartup()

Function called at TPM2_Startup()

```
11  BOOL
12  CryptRsaStartup(
13      void
14      )
15  {
16      return TRUE;
17  }
```

10.2.17.4 Internal Functions

10.2.17.4.1 RsaInitializeExponent()

This function initializes the bignum data structure that holds the private exponent. This function returns the pointer to the private exponent value so that it can be used in an initializer for a data declaration.

```
18  static privateExponent *
19  RsaInitializeExponent(
20      privateExponent       *Z
21      )
22  {
23      bigNum                *bn = (bigNum *)&Z->P;
24      int                    i;
25  //
```

```
26      for(i = 0; i < 5; i++)
27      {
28          bn[i] = (bigNum)&Z->entries[i];
29          BnInit(bn[i], BYTES_TO_CRYPT_WORDS(sizeof(Z->entries[0].d)));
30      }
31      return Z;
32  }
```

10.2.17.4.2 MakePgreaterThanQ()

This function swaps the pointers for P and Q if Q happens to be larger than Q.

```
33  static void
34  MakePgreaterThanQ(
35      privateExponent          *Z
36  )
37  {
38      if(BnUnsignedCmp(Z->P, Z->Q) < 0)
39      {
40          bigNum          bnT = Z->P;
41          Z->P = Z->Q;
42          Z->Q = bnT;
43      }
44  }
```

10.2.17.4.3 PackExponent()

This function takes the bignum private exponent and converts it into TPM2B form. In this form, the size field contains the overall size of the packed data. The buffer contains 5, equal sized values in P, Q, *dP*, *dQ*, *qInv* order. For example, if a key has a 2Kb public key, then the packed private key will contain 5, 1Kb values. This form makes it relatively easy to load and save the values without changing the normal unmarshaling to do anything more than allow a larger TPM2B for the private key. Also, when exporting the value, all that is needed is to change the size field of the private key in order to save just the P value.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure // The data is too big to fit

```
45  static BOOL
46  PackExponent(
47      TPM2B_PRIVATE_KEY_RSA       *packed,
48      privateExponent             *Z
49  )
50  {
51      int                         i;
52      UINT16                      primeSize = (UINT16)BITS_TO_BYTES(BnMsb(Z->P));
53      UINT16                      pS = primeSize;
54  //
55      pAssert((primeSize * 5) <= sizeof(packed->t.buffer));
56      packed->t.size = (primeSize * 5) + RSA_prime_flag;
57      for(i = 0; i < 5; i++)
58          if(!BnToBytes((bigNum)&Z->entries[i], &packed->t.buffer[primeSize * i], &pS))
59              return FALSE;
60      if(pS != primeSize)
61          return FALSE;
62      return TRUE;
63  }
```

 Copyright © TCG 2006-2020

10.2.17.4.4 UnpackExponent()

This function unpacks the private exponent from its TPM2B form into its bignum form.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	TPM2B is not the correct size

```
64  static BOOL
65  UnpackExponent(
66      TPM2B_PRIVATE_KEY_RSA       *b,
67      privateExponent             *Z
68  )
69  {
70          UINT16                 primeSize = b->t.size & ~RSA_prime_flag;
71          int                    i;
72          bigNum                *bn = &Z->P;
73  //
74      VERIFY(b->t.size & RSA_prime_flag);
75      RsaInitializeExponent(Z);
76      VERIFY((primeSize % 5) == 0);
77      primeSize /= 5;
78      for(i = 0; i < 5; i++)
79          VERIFY(BnFromBytes(bn[i], &b->t.buffer[primeSize * i], primeSize)
80                  != NULL);
81      MakePgreaterThanQ(Z);
82      return TRUE;
83  Error:
84      return FALSE;
85   }
```

10.2.17.4.5 ComputePrivateExponent()

This function computes the private exponent from the primes.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
86  static BOOL
87  ComputePrivateExponent(
88      bigNum                pubExp,         // IN: the public exponent
89      privateExponent      *Z               // IN/OUT: on input, has primes P and Q. On
90                                            //         output, has P, Q, dP, dQ, and pInv
91      )
92  {
93      BOOL                 pOK;
94      BOOL                 qOK;
95      BN_PRIME(pT);
96  //
97      // make p the larger value so that m2 is always less than p
98      MakePgreaterThanQ(Z);
99
100     //dP = (1/e) mod (p-1)
101     pOK = BnSubWord(pT, Z->P, 1);
102     pOK = pOK && BnModInverse(Z->dP, pubExp, pT);
103     //dQ = (1/e) mod (q-1)
104     qOK = BnSubWord(pT, Z->Q, 1);
105     qOK = qOK && BnModInverse(Z->dQ, pubExp, pT);
106     // qInv = (1/q) mod p
```

```
107         if(pOK && qOK)
108             pOK = qOK = BnModInverse(Z->qInv, Z->Q, Z->P);
109         if(!pOK)
110             BnSetWord(Z->P, 0);
111         if(!qOK)
112             BnSetWord(Z->Q, 0);
113         return pOK && qOK;
114     }
```

10.2.17.4.6 RsaPrivateKeyOp()

This function is called to do the exponentiation with the private key. Compile options allow use of the simple (but slow) private exponent, or the more complex but faster CRT method.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
115     static BOOL
116     RsaPrivateKeyOp(
117         bigNum               inOut, // IN/OUT: number to be exponentiated
118         privateExponent     *Z
119         )
120     {
121         BN_RSA(M1);
122         BN_RSA(M2);
123         BN_RSA(M);
124         BN_RSA(H);
125     //
126         MakePgreaterThanQ(Z);
127         // m1 = cdP mod p
128         VERIFY(BnModExp(M1, inOut, Z->dP, Z->P));
129         // m2 = cdQ mod q
130         VERIFY(BnModExp(M2, inOut, Z->dQ, Z->Q));
131         // h = qInv * (m1 - m2) mod p = qInv * (m1 + P - m2) mod P because Q < P
132         // so m2 < P
133         VERIFY(BnSub(H, Z->P, M2));
134         VERIFY(BnAdd(H, H, M1));
135         VERIFY(BnModMult(H, H, Z->qInv, Z->P));
136         // m = m2 + h * q
137         VERIFY(BnMult(M, H, Z->Q));
138         VERIFY(BnAdd(inOut, M2, M));
139         return TRUE;
140     Error:
141         return FALSE;
142     }
```

10.2.17.4.7 RSAEP()

This function performs the RSAEP operation defined in PKCS#1v2.1. It is an exponentiation of a value (*m*) with the public exponent (*e*), modulo the public (*n*).

Error Returns	Meaning
TPM_RC_VALUE	number to exponentiate is larger than the modulus

```
143     static TPM_RC
144     RSAEP(
145         TPM2B       *dInOut,        // IN: size of the encrypted block and the size of
146                                     //     the encrypted value. It must be the size of
```

```
147                                     //      the modulus.
148                                     // OUT: the encrypted data. Will receive the
149                                     //      decrypted value
150         OBJECT      *key            // IN: the key to use
151         )
152     {
153         TPM2B_TYPE(4BYTES, 4);
154         TPM2B_4BYTES        e2B;
155         UINT32              e = key->publicArea.parameters.rsaDetail.exponent;
156     //
157         if(e == 0)
158             e = RSA_DEFAULT_PUBLIC_EXPONENT;
159         UINT32_TO_BYTE_ARRAY(e, e2B.t.buffer);
160         e2B.t.size = 4;
161         return ModExpB(dInOut->size, dInOut->buffer, dInOut->size, dInOut->buffer,
162                        e2B.t.size, e2B.t.buffer, key->publicArea.unique.rsa.t.size,
163                        key->publicArea.unique.rsa.t.buffer);
164     }
```

10.2.17.4.8 RSADP()

This function performs the RSADP operation defined in PKCS#1v2.1. It is an exponentiation of a value (*c*) with the private exponent (*d*), modulo the public modulus (*n*). The decryption is in place.

This function also checks the size of the private key. If the size indicates that only a prime value is present, the key is converted to being a private exponent.

Error Returns	Meaning
TPM_RC_SIZE	the value to decrypt is larger than the modulus

```
165     static TPM_RC
166     RSADP(
167         TPM2B           *inOut,         // IN/OUT: the value to encrypt
168         OBJECT          *key            // IN: the key
169         )
170     {
171         BN_RSA_INITIALIZED(bnM, inOut);
172         NEW_PRIVATE_EXPONENT(Z);
173         if(UnsignedCompareB(inOut->size, inOut->buffer,
174                             key->publicArea.unique.rsa.t.size,
175                             key->publicArea.unique.rsa.t.buffer) >= 0)
176             return TPM_RC_SIZE;
177         // private key operation requires that private exponent be loaded
178         // During self-test, this might not be the case so load it up if it hasn't
179         // already done
180         // been done
181         if((key->sensitive.sensitive.rsa.t.size & RSA_prime_flag) == 0)
182         {
183             if(CryptRsaLoadPrivateExponent(&key->publicArea, &key->sensitive)
184                != TPM_RC_SUCCESS)
185                 return TPM_RC_BINDING;
186         }
187         VERIFY(UnpackExponent(&key->sensitive.sensitive.rsa, Z));
188         VERIFY(RsaPrivateKeyOp(bnM, Z));
189         VERIFY(BnTo2B(bnM, inOut, inOut->size));
190         return TPM_RC_SUCCESS;
191     Error:
192         return TPM_RC_FAILURE;
193     }
```

10.2.17.4.9 OaepEncode()

This function performs OAEP padding. The size of the buffer to receive the OAEP padded data must equal the size of the modulus

Error Returns	Meaning
TPM_RC_VALUE	*hashAlg* is not valid or message size is too large

```
194  static TPM_RC
195  OaepEncode(
196      TPM2B        *padded,         // OUT: the pad data
197      TPM_ALG_ID    hashAlg,        // IN: algorithm to use for padding
198      const TPM2B *label,           // IN: null-terminated string (may be NULL)
199      TPM2B        *message,        // IN: the message being padded
200      RAND_STATE   *rand            // IN: the random number generator to use
201      )
202  {
203      INT32         padLen;
204      INT32         dbSize;
205      INT32         i;
206      BYTE          mySeed[MAX_DIGEST_SIZE];
207      BYTE         *seed = mySeed;
208      UINT16        hLen = CryptHashGetDigestSize(hashAlg);
209      BYTE          mask[MAX_RSA_KEY_BYTES];
210      BYTE         *pp;
211      BYTE         *pm;
212      TPM_RC        retVal = TPM_RC_SUCCESS;
213
214      pAssert(padded != NULL && message != NULL);
215
216      // A value of zero is not allowed because the KDF can't produce a result
217      // if the digest size is zero.
218      if(hLen == 0)
219          return TPM_RC_VALUE;
220

```

10.2.17.4.10 OaepDecode()

This function performs OAEP padding checking. The size of the buffer to receive the recovered data. If the padding is not valid, the *dSize* size is set to zero and the function returns TPM_RC_VALUE.

The *dSize* parameter is used as an input to indicate the size available in the buffer. If insufficient space is available, the size is not changed and the return code is TPM_RC_VALUE.

Error Returns	Meaning
TPM_RC_VALUE	the value to decode was larger than the modulus, or the padding is wrong or the buffer to receive the results is too small

```
275     static TPM_RC
276     OaepDecode(

413         return TPM_RC_SUCCESS;
414     }
```

10.2.17.4.13 CryptRsaPssSaltSize()

This function computes the salt size used in PSS. It is broken out so that the X509 code can get the same value that is used by the encoding function in this module.

```
415     INT16
416     CryptRsaPssSaltSize(
417         INT16              hashSize,
418         INT16               outSize
419     )
420     {
421         INT16               saltSize;
422     //
423         // (Mask Length) = (outSize - hashSize - 1);
424         // Max saltSize is (Mask Length) - 1
425         saltSize = (outSize - hashSize - 1) - 1;
426         // Use the maximum salt size allowed by FIPS 186-4
427         if(saltSize > hashSize)
428             saltSize = hashSize;
429         else if(saltSize < 0)
430             saltSize = 0;
431         return saltSize;
432     }
```

10.2.17.4.14 PssEncode()

This function creates an encoded block of data that is the size of modulus. The function uses the maximum salt size that will fit in the encoded block.

Returns TPM_RC_SUCCESS or goes into failure mode.

```
433     static TPM_RC
434     PssEncode(
435         TPM2B           *out,       // OUT: the encoded buffer
436         TPM_ALG_ID       hashAlg,   // IN: hash algorithm for the encoding
437         TPM2B           *digest,    // IN: the digest
438         RAND_STATE      *rand       // IN: random number source
439         )
440     {
441         UINT32                hLen = CryptHashGetDigestSize(hashAlg);
442         BYTE                  salt[MAX_RSA_KEY_BYTES - 1];
443         UINT16                saltSize;
444         BYTE                 *ps = salt;
445         BYTE                 *pOut;
446         UINT16                mLen;
447         HASH_STATE            hashState;
448
449         // These are fatal errors indicating bad TPM firmware
450         pAssert(out != NULL && hLen > 0 && digest != NULL);

453         mLen = (UINT16)(out->size - hLen - 1);
454
455         // Set the salt size
456         saltSize = CryptRsaPssSaltSize((INT16)hLen, (INT16)out->size);
457
458     //using eOut for scratch space
```

 Copyright © TCG 2006-2020

```
459     // Set the first 8 bytes to zero
460     pOut = out->buffer;
461     memset(pOut, 0, 8);
462
463     // Get set the salt
464     DRBG_Generate(rand, salt, saltSize);
465     if(g_inFailureMode)
466         return TPM_RC_FAILURE;
467
468     // Create the hash of the pad || input hash || salt
469     CryptHashStart(&hashState, hashAlg);
470     CryptDigestUpdate(&hashState, 8, pOut);
471     CryptDigestUpdate2B(&hashState, digest);
472     CryptDigestUpdate(&hashState, saltSize, salt);
473     CryptHashEnd(&hashState, hLen, &pOut[out->size - hLen - 1]);
474
475     // Create a mask
476     if(CryptMGF1(mLen, pOut, hashAlg, hLen, &pOut[mLen]) != mLen)
477         FAIL(FATAL_ERROR_INTERNAL);
478
479     // Since this implementation uses key sizes that are all even multiples of
480     // 8, just need to make sure that the most significant bit is CLEAR
481     *pOut &= 0x7f;
482
483     // Before we mess up the pOut value, set the last byte to 0xbc
484     pOut[out->size - 1] = 0xbc;
485
486     // XOR a byte of 0x01 at the position just before where the salt will be XOR'ed
487     pOut = &pOut[mLen - saltSize - 1];
488     *pOut++ ^= 0x01;
489
490     // XOR the salt data into the buffer
491     for(; saltSize > 0; saltSize--)
492         *pOut++ ^= *ps++;
493
494     // and we are done
495     return TPM_RC_SUCCESS;
496 }
```

10.2.17.4.15 PssDecode()

This function checks that the PSS encoded block was built from the provided digest. If the check is successful, TPM_RC_SUCCESS is returned. Any other value indicates an error.

This implementation of PSS decoding is intended for the reference TPM implementation and is not at all generalized. It is used to check signatures over hashes and assumptions are made about the sizes of values. Those assumptions are enforce by this implementation. This implementation does allow for a variable size salt value to have been used by the creator of the signature.

Error Returns	Meaning
TPM_RC_SCHEME	*hashAlg* is not a supported hash algorithm
TPM_RC_VALUE	decode operation failed

```
497 static TPM_RC
498 PssDecode(
499     TPM_ALG_ID   hashAlg,        // IN: hash algorithm to use for the encoding
500     TPM2B       *dIn,            // In: the digest to compare
501     TPM2B       *eIn             // IN: the encoded data
502     )
503 {
504     UINT32           hLen = CryptHashGetDigestSize(hashAlg);
505     BYTE             mask[MAX_RSA_KEY_BYTES];
```

```
506         BYTE             *pm = mask;
507         BYTE             *pe;
508         BYTE              pad[8] = {0};

10.2.17.5 Externally Accessible Functions

10.2.17.5.1 CryptRsaSelectScheme()

This function is used by TPM2_RSA_Decrypt() and TPM2_RSA_Encrypt(). It sets up the rules to select a scheme between input and object default. This function assume the RSA object is loaded. If a default scheme is defined in object, the default scheme should be chosen, otherwise, the input scheme should be chosen. In the case that both the object and *scheme* are not TPM_ALG_NULL, then if the schemes are the same, the input scheme will be chosen. if the scheme are not compatible, a NULL pointer will be returned.

The return pointer may point to a TPM_ALG_NULL scheme.

```
728  TPMT_RSA_DECRYPT*
729  CryptRsaSelectScheme(
730      TPMI_DH_OBJECT       rsaHandle,     // IN: handle of an RSA key
731      TPMT_RSA_DECRYPT    *scheme         // IN: a sign or decrypt scheme
732      )
733  {
734      OBJECT              *rsaObject;
735      TPMT_ASYM_SCHEME    *keyScheme;
736      TPMT_RSA_DECRYPT    *retVal = NULL;
737
738      // Get sign object pointer
739      rsaObject = HandleToObject(rsaHandle);
740      keyScheme = &rsaObject->publicArea.parameters.asymDetail.scheme;
741
742      // if the default scheme of the object is TPM_ALG_NULL, then select the
743      // input scheme
744      if(keyScheme->scheme == TPM_ALG_NULL)
745      {
746          retVal = scheme;
747      }
748      // if the object scheme is not TPM_ALG_NULL and the input scheme is
749      // TPM_ALG_NULL, then select the default scheme of the object.
750      else if(scheme->scheme == TPM_ALG_NULL)
751      {
752          // if input scheme is NULL
753          retVal = (TPMT_RSA_DECRYPT *)keyScheme;
754      }
755      // get here if both the object scheme and the input scheme are
756      // not TPM_ALG_NULL. Need to insure that they are the same.
757      // IMPLEMENTATION NOTE: This could cause problems if future versions have
758      // schemes that have more values than just a hash algorithm. A new function
759      // (IsSchemeSame()) might be needed then.
760      else if(keyScheme->scheme == scheme->scheme
761              && keyScheme->details.anySig.hashAlg == scheme->details.anySig.hashAlg)
762      {
763          retVal = scheme;
764      }
765      // two different, incompatible schemes specified will return NULL
766      return retVal;
767  }
```

10.2.17.5.2 CryptRsaLoadPrivateExponent()

This function is called to generate the private exponent of an RSA key.

 Copyright © TCG 2006-2020

Error Returns	Meaning
TPM_RC_BINDING	public and private parts of *rsaKey* are not matched

```
768  TPM_RC
769  CryptRsaLoadPrivateExponent(
770      TPMT_PUBLIC            *publicArea,

809      return TPM_RC_SUCCESS;
810  Error:
811      return TPM_RC_BINDING;
812  }
```

10.2.17.5.3 CryptRsaEncrypt()

This is the entry point for encryption using RSA. Encryption is use of the public exponent. The padding parameter determines what padding will be used.

The *cOutSize* parameter must be at least as large as the size of the key.

If the padding is RSA_PAD_NONE, *dIn* is treated as a number. It must be lower in value than the key modulus.

 Copyright © TCG 2006-2020

NOTE: If *dIn* has fewer bytes than *cOut*, then we don't add low-order zeros to *dIn* to make it the size of the RSA key for the call to RSAEP. This is because the high order bytes of *dIn* might have a numeric value that is greater than the value of the key modulus. If this had low-order zeros added, it would have a numeric value larger than the modulus even though it started out with a lower numeric value.

Error Returns	Meaning
TPM_RC_VALUE	*cOutSize* is too small (must be the size of the modulus)
TPM_RC_SCHEME	*padType* is not a supported scheme

```
813  LIB_EXPORT TPM_RC
814  CryptRsaEncrypt(
815      TPM2B_PUBLIC_KEY_RSA        *cOut,          // OUT: the encrypted data

```

10.2.17.5.4 CryptRsaDecrypt()

This is the entry point for decryption using RSA. Decryption is use of the private exponent. The *padType* parameter determines what padding was used.

Error Returns	Meaning
TPM_RC_SIZE	*cInSize* is not the same as the size of the public modulus of *key*; or numeric value of the encrypted data is greater than the modulus
TPM_RC_VALUE	*dOutSize* is not large enough for the result
TPM_RC_SCHEME	*padType* is not supported

```
880 LIB_EXPORT TPM_RC
881 CryptRsaDecrypt(
882     TPM2B               *dOut,          // OUT: the decrypted data
883     TPM2B               *cIn,           // IN: the data to decrypt
884     OBJECT              *key,           // IN: the key to use for decryption
885     TPMT_RSA_DECRYPT    *scheme,        // IN: the padding scheme

```

10.2.18 CryptSmac.c

10.2.18.1 Introduction

This file contains the implementation of the message authentication codes based on a symmetric block cipher. These functions only use the single block encryption functions of the selected symmetric cryptographic library.

10.2.18.2 Includes, Defines, and Typedefs

```
1   #define _CRYPT_HASH_C_
2   #include "Tpm.h"
3   #if SMAC_IMPLEMENTED
```

10.2.18.2.1 CryptSmacStart()

Function to start an SMAC.

```
4   UINT16
5   CryptSmacStart(
6       HASH_STATE              *state,
7       TPMU_PUBLIC_PARMS       *keyParameters,
8       TPM_ALG_ID               macAlg,          // IN: the type of MAC
9       TPM2B                   *key
10  )
11  {
12      UINT16                  retVal = 0;
13  //
14      // Make sure that the key size is correct. This should have been checked
15      // at key load, but...
16      if(BITS_TO_BYTES(keyParameters->symDetail.sym.keyBits.sym) == key->size)
17      {
18          switch(macAlg)
19          {
20  #if ALG_CMAC
21              case ALG_CMAC_VALUE:
22                  retVal = CryptCmacStart(&state->state.smac, keyParameters,
23                                          macAlg, key);
24                  break;
25  #endif
26              default:
27                  break;
28          }
29      }
30      state->type = (retVal != 0) ? HASH_STATE_SMAC : HASH_STATE_EMPTY;
31      return retVal;
32  }
```

10.2.18.2.2 CryptMacStart()

Function to start either an HMAC or an SMAC. Cannot reuse the CryptHmacStart() function because of the difference in number of parameters.

```
33  UINT16
34  CryptMacStart(
35      HMAC_STATE              *state,
36      TPMU_PUBLIC_PARMS       *keyParameters,
37      TPM_ALG_ID               macAlg,          // IN: the type of MAC
38      TPM2B                   *key
```

```
39  )
40  {
41      MemorySet(state, 0, sizeof(HMAC_STATE));
42      if(CryptHashIsValidAlg(macAlg, FALSE))
43      {
44          return CryptHmacStart(state, macAlg, key->size, key->buffer);
45      }
46      else if(CryptSmacIsValidAlg(macAlg, FALSE))
47      {
48          return CryptSmacStart(&state->hashState, keyParameters, macAlg, key);
49      }
50      else
51          return 0;
52  }
```

10.2.18.2.3 CryptMacEnd()

Dispatch to the MAC end function using a size and buffer pointer.

```
53  UINT16
54  CryptMacEnd(
55      HMAC_STATE          *state,
56      UINT32               size,
57      BYTE                *buffer
58  )
59  {
60      UINT16              retVal = 0;
61      if(state->hashState.type == HASH_STATE_SMAC)
62          retVal = (state->hashState.state.smac.smacMethods.end)(
63                      &state->hashState.state.smac.state, size, buffer);
64      else if(state->hashState.type == HASH_STATE_HMAC)
65          retVal = CryptHmacEnd(state, size, buffer);
66      state->hashState.type = HASH_STATE_EMPTY;
67      return retVal;
68  }
```

10.2.18.2.4 CryptMacEnd2B()

Dispatch to the MAC end function using a 2B.

```
69  UINT16
70  CryptMacEnd2B (
71      HMAC_STATE          *state,
72      TPM2B               *data
73  )
74  {
75      return CryptMacEnd(state, data->size, data->buffer);
76  }
77  #endif // SMAC_IMPLEMENTED
```

10.2.19 CryptSym.c

10.2.19.1 Introduction

This file contains the implementation of the symmetric block cipher modes allowed for a TPM. These functions only use the single block encryption functions of the selected symmetric crypto library.

10.2.19.2 Includes, Defines, and Typedefs

```
1   #include "Tpm.h"
2   #include "CryptSym.h"
3   #define     KEY_BLOCK_SIZES(ALG, alg)                                              \
4   static const INT16       alg##KeyBlockSizes[] = {                               \
5                                  ALG##_KEY_SIZES_BITS, -1, ALG##_BLOCK_SIZES };
6   #if ALG_AES
7       KEY_BLOCK_SIZES(AES, aes);
8   #endif // ALG_AES
9   #if ALG_SM4
10      KEY_BLOCK_SIZES(SM4, sm4);
11  #endif
12  #if ALG_CAMELLIA
13      KEY_BLOCK_SIZES(CAMELLIA, camellia);
14  #endif
15  #if ALG_TDES
16      KEY_BLOCK_SIZES(TDES, tdes);
17  #endif
```

10.2.19.3 Initialization and Data Access Functions

10.2.19.3.1 CryptSymInit()

This function is called to do _TPM_Init() processing

```
18  BOOL
19  CryptSymInit(
20      void
21      )
22  {
23      return TRUE;
24  }
```

10.2.19.3.2 CryptSymStartup()

This function is called to do TPM2_Startup() processing

```
25  BOOL
26  CryptSymStartup(
27      void
28      )
29  {
30      return TRUE;
31  }
```

10.2.19.3.3 CryptGetSymmetricBlockSize()

This function returns the block size of the algorithm. The table of bit sizes has an entry for each allowed key size. The entry for a key size is 0 if the TPM does not implement that key size. The key size table is

delimited with a negative number (-1). After the delimiter is a list of block sizes with each entry corresponding to the key bit size. For most symmetric algorithms, the block size is the same regardless of the key size but this arrangement allows them to be different.

Return Value	Meaning
0	cipher not supported
0	the cipher block size in bytes

```
32  LIB_EXPORT INT16
33  CryptGetSymmetricBlockSize(
34      TPM_ALG_ID      symmetricAlg,   // IN: the symmetric algorithm
35      UINT16          keySizeInBits   // IN: the key size
36      )
37  {
38      const INT16    *sizes;
39      INT16           i;

10.2.21 RsaKeyCache.c

10.2.21.1 Introduction

This file contains the functions to implement the RSA key cache that can be used to speed up simulation.

Only one key is created for each supported key size and it is returned whenever a key of that size is requested.

If desired, the key cache can be populated from a file. This allows multiple TPM to run with the same RSA keys. Also, when doing simulation, the DRBG will use preset sequences so it is not too hard to repeat sequences for debug or profile or stress.

When the key cache is enabled, a call to CryptRsaGenerateKey() will call the GetCachedRsaKey(). If the cache is enabled and populated, then the cached key of the requested size is returned. If a key of the requested size is not available, the no key is loaded and the requested key will need to be generated. If the cache is not populated, the TPM will open a file that has the appropriate name for the type of keys required (CRT or no-CRT). If the file is the right size, it is used. If the file doesn't exist or the file does not have the correct size, the TMP will populate the cache with new keys of the required size and write the cache data to the file so that they will be available the next time.

Currently, if two simulations are being run with TPM's that have different RSA key sizes (e.g,, one with 1024 and 2048 and another with 2048 and 3072, then the files will not match for the both of them and they will both try to overwrite the other's cache file. I may try to do something about this if necessary.

10.2.21.2 Includes, Types, Locals, and Defines

```
1   #include "Tpm.h"
2   #if USE_RSA_KEY_CACHE
3   #include  <stdio.h>
4   #include "RsaKeyCache_fp.h"
5   #if CRT_FORMAT_RSA == YES
6   #define CACHE_FILE_NAME "RsaKeyCacheCrt.data"
7   #else
8   #define CACHE_FILE_NAME "RsaKeyCacheNoCrt.data"
9   #endif
10  typedef struct _RSA_KEY_CACHE_
11  {
12      TPM2B_PUBLIC_KEY_RSA        publicModulus;
13      TPM2B_PRIVATE_KEY_RSA       privateExponent;
14  } RSA_KEY_CACHE;
```

Determine the number of RSA key sizes for the cache

```
15  TPMI_RSA_KEY_BITS       SupportedRsaKeySizes[] = {
16  #if RSA_1024
17      1024,
18  #endif
19  #if RSA_2048
20      2048,
21  #endif
22  #if RSA_3072
23      3072,
24  #endif
25  #if RSA_4096
26      4096,
27  #endif
28      0
29  };
30
31  #define RSA_KEY_CACHE_ENTRIES (RSA_1024 + RSA_2048 + RSA_3072 + RSA_4096)
```

 Copyright © TCG 2006-2020

The key cache holds one entry for each of the supported key sizes

```
32  RSA_KEY_CACHE          s_rsaKeyCache[RSA_KEY_CACHE_ENTRIES];
33  // Indicates if the key cache is loaded. It can be loaded and enabled or disabled.
34  BOOL                   s_keyCacheLoaded = 0;
35
36  // Indicates if the key cache is enabled
37  int                    s_rsaKeyCacheEnabled = FALSE;
38
39  //*** RsaKeyCacheControl()
40  // Used to enable and disable the RSA key cache.
41  LIB_EXPORT void
42  RsaKeyCacheControl(
43      int                state
44      )
45  {
46      s_rsaKeyCacheEnabled = state;
47  }
```

10.2.21.2.1 InitializeKeyCache()

This will initialize the key cache and attempt to write it to a file for later use.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
48  static BOOL
49  InitializeKeyCache(
50      TPMT_PUBLIC         *publicArea,
51      TPMT_SENSITIVE      *sensitive,
52      RAND_STATE          *rand               // IN: if not NULL, the deterministic
53                                              //     RNG state
54      )
55  {
56      int                  index;
57      TPM_KEY_BITS         keySave = publicArea->parameters.rsaDetail.keyBits;
58      BOOL                 OK = TRUE;
59  //
60      s_rsaKeyCacheEnabled = FALSE;
61      for(index = 0; OK && index < RSA_KEY_CACHE_ENTRIES; index++)
62      {
63          publicArea->parameters.rsaDetail.keyBits
64              = SupportedRsaKeySizes[index];
65          OK = (CryptRsaGenerateKey(publicArea, sensitive, rand) == TPM_RC_SUCCESS);
66          if(OK)
67          {
68              s_rsaKeyCache[index].publicModulus = publicArea->unique.rsa;
69              s_rsaKeyCache[index].privateExponent = sensitive->sensitive.rsa;
70          }
71      }
72      publicArea->parameters.rsaDetail.keyBits = keySave;
73      s_keyCacheLoaded = OK;
74  #if SIMULATION && USE_RSA_KEY_CACHE && USE_KEY_CACHE_FILE
75      if(OK)
76      {
77          FILE                *cacheFile;
78          const char          *fn = CACHE_FILE_NAME;
79
80  #if defined _MSC_VER
81          if(fopen_s(&cacheFile, fn, "w+b") != 0)
82  #else
```

```
83          cacheFile = fopen(fn, "w+b");
84          if(NULL == cacheFile)
85  #endif
86          {
87              printf("Can't open %s for write.\n", fn);
88          }
89          else
90          {
91              fseek(cacheFile, 0, SEEK_SET);
92              if(fwrite(s_rsaKeyCache, 1, sizeof(s_rsaKeyCache), cacheFile)
93                 != sizeof(s_rsaKeyCache))
94              {
95                  printf("Error writing cache to %s.", fn);
96              }
97          }
98          if(cacheFile)
99              fclose(cacheFile);
100     }
101 #endif
102     return s_keyCacheLoaded;
103 }
```

10.2.21.2.2 KeyCacheLoaded()

Checks that key cache is loaded.

Return Value	Meaning
TRUE(1)	cache loaded
FALSE(0)	cache not loaded

```
104 static BOOL
105 KeyCacheLoaded(
106     TPMT_PUBLIC         *publicArea,
107     TPMT_SENSITIVE      *sensitive,

109                                             //     RNG state
110     )
111 {
112 #if SIMULATION && USE_RSA_KEY_CACHE && USE_KEY_CACHE_FILE
113     if(!s_keyCacheLoaded)
114     {
115         FILE            *cacheFile;
116         const char *     fn = CACHE_FILE_NAME;
117 #if defined _MSC_VER && 1
118         if(fopen_s(&cacheFile, fn, "r+b") == 0)
119 #else
120         cacheFile = fopen(fn, "r+b");
121         if(NULL != cacheFile)
122 #endif
123         {
124             fseek(cacheFile, 0L, SEEK_END);
125             if(ftell(cacheFile) == sizeof(s_rsaKeyCache))
126             {
127                 fseek(cacheFile, 0L, SEEK_SET);
128                 s_keyCacheLoaded = (
129                     fread(&s_rsaKeyCache, 1, sizeof(s_rsaKeyCache), cacheFile)
130                     == sizeof(s_rsaKeyCache));
131             }
132             fclose(cacheFile);
133         }
134     }
135 #endif
```

```
136     if(!s_keyCacheLoaded)
137         s_rsaKeyCacheEnabled = InitializeKeyCache(publicArea, sensitive, rand);
138     return s_keyCacheLoaded;
139 }
```

10.2.21.2.3 GetCachedRsaKey()

Return Value	Meaning
TRUE(1)	key loaded
FALSE(0)	key not loaded

```
140 BOOL
141 GetCachedRsaKey(
142     TPMT_PUBLIC         *publicArea,
143     TPMT_SENSITIVE      *sensitive,
144     RAND_STATE          *rand               // IN: if not NULL, the deterministic
145                                             //     RNG state
146     )
147 {
148     int                      keyBits = publicArea->parameters.rsaDetail.keyBits;
149     int                      index;
150 //
151     if(KeyCacheLoaded(publicArea, sensitive, rand))
152     {
153         for(index = 0; index < RSA_KEY_CACHE_ENTRIES; index++)

159                 return TRUE;
160             }
161         }
162         return FALSE;
163     }
164     return s_keyCacheLoaded;
165 }
166 #endif  // defined SIMULATION && defined USE_RSA_KEY_CACHE
```

10.2.22 Ticket.c

10.2.22.1 Introduction

This clause contains the functions used for ticket computations.

10.2.22.2 Includes

```
1   #include "Tpm.h"
```

10.2.22.3 Functions

10.2.22.3.1 TicketIsSafe()

This function indicates if producing a ticket is safe. It checks if the leading bytes of an input buffer is TPM_GENERATED_VALUE or its substring of canonical form. If so, it is not safe to produce ticket for an input buffer claiming to be TPM generated buffer

Return Value	Meaning
TRUE(1)	safe to produce ticket
FALSE(0)	not safe to produce ticket

```
2   BOOL
3   TicketIsSafe(
4       TPM2B           *buffer
5       )
6   {
7       TPM_GENERATED   valueToCompare = TPM_GENERATED_VALUE;
8       BYTE            bufferToCompare[sizeof(valueToCompare)];
9       BYTE            *marshalBuffer;
10  //
11      // If the buffer size is less than the size of TPM_GENERATED_VALUE, assume
12      // it is not safe to generate a ticket
13      if(buffer->size < sizeof(valueToCompare))
14          return FALSE;
15      marshalBuffer = bufferToCompare;
16      TPM_GENERATED_Marshal(&valueToCompare, &marshalBuffer, NULL);
17      if(MemoryEqual(buffer->buffer, bufferToCompare, sizeof(valueToCompare)))
18          return FALSE;
19      else
20          return TRUE;
21  }
```

10.2.22.3.2 TicketComputeVerified()

This function creates a TPMT_TK_VERIFIED ticket.

```
22  void
23  TicketComputeVerified(
24      TPMI_RH_HIERARCHY    hierarchy,     // IN: hierarchy constant for ticket
25      TPM2B_DIGEST        *digest,        // IN: digest
26      TPM2B_NAME          *keyName,       // IN: name of key that signed the values
27      TPMT_TK_VERIFIED    *ticket         // OUT: verified ticket
28      )
29  {
30      TPM2B_PROOF         *proof;
31      HMAC_STATE           hmacState;
```

 Copyright © TCG 2006-2020

```
32  //
33      // Fill in ticket fields
34      ticket->tag = TPM_ST_VERIFIED;
35      ticket->hierarchy = hierarchy;
36      proof = HierarchyGetProof(hierarchy);
37
38      // Start HMAC using the proof value of the hierarchy as the HMAC key
39      ticket->digest.t.size = CryptHmacStart2B(&hmacState, CONTEXT_INTEGRITY_HASH_ALG,
40                                               &proof->b);
41          //  TPM_ST_VERIFIED
42      CryptDigestUpdateInt(&hmacState, sizeof(TPM_ST), ticket->tag);
43          //  digest
44      CryptDigestUpdate2B(&hmacState.hashState, &digest->b);
45          // key name
46      CryptDigestUpdate2B(&hmacState.hashState, &keyName->b);
47          // done
48      CryptHmacEnd2B(&hmacState, &ticket->digest.b);
49
50      return;
51  }
```

10.2.22.3.3 TicketComputeAuth()

This function creates a TPMT_TK_AUTH ticket.

```
52  void
53  TicketComputeAuth(
54      TPM_ST               type,          // IN: the type of ticket.
55      TPMI_RH_HIERARCHY    hierarchy,     // IN: hierarchy constant for ticket
56      UINT64               timeout,       // IN: timeout
57      BOOL                 expiresOnReset,// IN: flag to indicate if ticket expires on

10.2.23.2 Unmarshaling Functions

10.2.23.2.1 ASN1UnmarshalContextInitialize()

Function does standard initialization of a context.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
6   BOOL
7   ASN1UnmarshalContextInitialize(
8       ASN1UnmarshalContext    *ctx,
9       INT16                    size,
10      BYTE                    *buffer
11  )
12  {
13      VERIFY(buffer != NULL);
14      VERIFY(size > 0);
15      ctx->buffer = buffer;
16      ctx->size = size;
17      ctx->offset = 0;
18      ctx->tag = 0xFF;
19      return TRUE;
20  Error:
21      return FALSE;
22  }
```

10.2.23.2.2 ASN1DecodeLength()

This function extracts the length of an element from *buffer* starting at *offset*.

Return Value	Meaning
>=0	the extracted length
<0	an error

```
23  INT16
24  ASN1DecodeLength(
25      ASN1UnmarshalContext        *ctx
26  )
27  {
28      BYTE                first;                  // Next octet in buffer
29      INT16               value;
30  //
31      VERIFY(ctx->offset < ctx->size);
32      first = NEXT_OCTET(ctx);
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
33      // If the number of octets of the entity is larger than 127, then the first octet
34      // is the number of octets in the length specifier.
35      if(first >= 0x80)
36      {
37          // Make sure that this length field is contained with the structure being
38          // parsed
39          CHECK_SIZE(ctx, (first & 0x7F));
40          if(first == 0x82)
41          {
42              // Two octets of size
43              // get the next value
44              value = (INT16)NEXT_OCTET(ctx);
45              // Make sure that the result will fit in an INT16
46              VERIFY(value < 0x0080);
47              // Shift up and add next octet
48              value = (value << 8) + NEXT_OCTET(ctx);
49          }
50          else if(first == 0x81)
51              value = NEXT_OCTET(ctx);
52          // Sizes larger than will fit in a INT16 are an error
53          else
54              goto Error;
55      }
56      else
57          value = first;
58      // Make sure that the size defined something within the current context
59      CHECK_SIZE(ctx, value);
60      return value;
61  Error:
62      ctx->size = -1;              // Makes everything fail from now on.
63      return -1;
64  }
```

10.2.23.2.3 ASN1NextTag()

This function extracts the next type from *buffer* starting at *offset*. It advances *offset* as it parses the type and the length of the type. It returns the length of the type. On return, the *length* octets starting at *offset* are the octets of the type.

Return Value	Meaning
>=0	the number of octets in *type*
<0	an error

```
65  INT16
66  ASN1NextTag(
67      ASN1UnmarshalContext    *ctx
68  )
69  {
70      // A tag to get?
71      VERIFY(ctx->offset < ctx->size);
72      // Get it
73      ctx->tag = NEXT_OCTET(ctx);
74      // Make sure that it is not an extended tag
75      VERIFY((ctx->tag & 0x1F) != 0x1F);
76      // Get the length field and return that
77      return ASN1DecodeLength(ctx);
78
79  Error:
80      // Attempt to read beyond the end of the context or an illegal tag
81      ctx->size = -1;          // Persistent failure
82      ctx->tag = 0xFF;
83      return -1;
```

 Copyright © TCG 2006-2020

```
84     }
```

10.2.23.2.4 ASN1GetBitStringValue()

Try to parse a bit string of up to 32 bits from a value that is expected to be a bit string. The bit string is left justified so that the MSb of the input is the MSb of the returned value. If there is a general parsing error, the context->size is set to -1.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
85     BOOL
86     ASN1GetBitStringValue(
87         ASN1UnmarshalContext        *ctx,
88         UINT32                      *val
89     )
90     {
91         int                     shift;
92         INT16                   length;
93         UINT32                  value = 0;
94         int                     inputBits;
95     //
96         length = ASN1NextTag(ctx);
97         VERIFY(length >= 1);
98         VERIFY(ctx->tag == ASN1_BITSTRING);
99         // Get the shift value for the bit field (how many bits to lop off of the end)
100        shift = NEXT_OCTET(ctx);
101        length--;
102        // Get the number of bits in the input
103        inputBits = (8 * length) - shift;
104        // the shift count has to make sense
105        VERIFY((shift < 8) && ((length > 0) || (shift == 0)));
106        // if there are any bytes left
107        for(; length > 1; length--)
108        {
109
110            // for all but the last octet, just shift and add the new octet
111            VERIFY((value & 0xFF000000) == 0); // can't loose significant bits
112            value = (value << 8) + NEXT_OCTET(ctx);
113
114        }
115        if(length == 1)
116        {
117            // for the last octet, just shift the accumulated value enough to
118            // accept the significant bits in the last octet and shift the last
119            // octet down
120            VERIFY(((value & (0xFF000000 << (8 - shift)))) == 0);
121            value = (value << (8 - shift)) + (NEXT_OCTET(ctx) >> shift);
122
123        }
124        // 'Left justify' the result
125        if(inputBits > 0)
126            value <<= (32 - inputBits);
127        *val = value;
128        return TRUE;
129    Error:
130        ctx->size = -1;
131        return FALSE;
132    }
```

10.2.23.3 Marshaling Functions

10.2.23.3.1 Introduction

Marshaling of an ASN.1 structure is accomplished from the bottom up. That is, the things that will be at the end of the structure are added last. To manage the collecting of the relative sizes, start a context for the outermost container, if there is one, and then placing items in from the bottom up. If the bottom-most item is also within a structure, create a nested context by calling ASN1StartMarshalingContext().

The context control structure contains a *buffer* pointer, an *offset*, an *end* and a stack. *offset* is the offset from the start of the buffer of the last added byte. When *offset* reaches 0, the buffer is full. *offset* is a signed value so that, when it becomes negative, there is an overflow. Only two functions are allowed to move bytes into the buffer: ASN1PushByte() and ASN1PushBytes(). These functions make sure that no data is written beyond the end of the buffer.

When a new context is started, the current value of *end* is pushed on the stack and *end* is set to 'offset. As bytes are added, offset gets smaller. At any time, the count of bytes in the current context is simply *end* - *offset*.

Since starting a new context involves setting *end* = *offset*, the number of bytes in the context starts at 0. The nominal way of ending a context is to use *end* - *offset* to set the length value, and then a tag is added to the buffer. Then the previous *end* value is popped meaning that the context just ended becomes a member of the now current context.

The nominal strategy for building a completed ASN.1 structure is to push everything into the buffer and then move everything to the start of the buffer. The move is simple as the size of the move is the initial *end* value minus the final *offset* value. The destination is *buffer* and the source is *buffer* + *offset*. As Skippy would say "Easy peasy, Joe."

It is not necessary to provide a buffer into which the data is placed. If no buffer is provided, then the marshaling process will return values needed for marshaling. On strategy for filling the buffer would be to execute the process for building the structure without using a buffer. This would return the overall size of the structure. Then that amount of data could be allocated for the buffer and the fill process executed again with the data going into the buffer. At the end, the data would be in its final resting place.

10.2.23.3.2 ASN1InitialializeMarshalContext()

This creates a structure for handling marshaling of an ASN.1 formatted data structure.

```
133 void
134 ASN1InitialializeMarshalContext(
135     ASN1MarshalContext      *ctx,
136     INT16                    length,
137     BYTE                    *buffer
138 )
139 {
140     ctx->buffer = buffer;
141     if(buffer)
142         ctx->offset = length;
143     else
144         ctx->offset = INT16_MAX;
145     ctx->end = ctx->offset;
146     ctx->depth = -1;
147 }
```

10.2.23.3.3 ASN1StartMarshalContext()

This starts a new constructed element. It is constructed on *top* of the value that was previously placed in the structure.

 Copyright © TCG 2006-2020

```
148 void
149 ASN1StartMarshalContext(
150     ASN1MarshalContext      *ctx
151 )
152 {
153     pAssert((ctx->depth + 1) < MAX_DEPTH);
154     ctx->depth++;
155     ctx->ends[ctx->depth] = ctx->end;
156     ctx->end = ctx->offset;
157 }
```

10.2.23.3.4 ASN1EndMarshalContext()

This function restores the end pointer for an encapsulating structure.

Return Value	Meaning
0	the size of the encapsulated structure that was just ended
0	an error

```
158 INT16
159 ASN1EndMarshalContext(
160     ASN1MarshalContext      *ctx
161 )
162 {
163     INT16                   length;
164     pAssert(ctx->depth >= 0);
165     length = ctx->end - ctx->offset;
166     ctx->end = ctx->ends[ctx->depth--];
167     if((ctx->depth == -1) && (ctx->buffer))
168     {
169         MemoryCopy(ctx->buffer, ctx->buffer + ctx->offset, ctx->end - ctx->offset);
170     }
171     return length;
172 }
```

10.2.23.3.5 ASN1EndEncapsulation()

This function puts a tag and length in the buffer. In this function, an embedded BIT_STRING is assumed to be a collection of octets. To indicate that all bits are used, a byte of zero is prepended. If a raw bit-string is needed, a new function like ASN1PushInteger() would be needed.

Return Value	Meaning
0	number of octets in the encapsulation
0	failure

```
173 UINT16
174 ASN1EndEncapsulation(
175     ASN1MarshalContext          *ctx,
176     BYTE                         tag
177 )
178 {
179     // only add a leading zero for an encapsulated BIT STRING
180     if (tag == ASN1_BITSTRING)
181         ASN1PushByte(ctx, 0);
182     ASN1PushTagAndLength(ctx, tag, ctx->end - ctx->offset);
183     return ASN1EndMarshalContext(ctx);
184 }
```

 Copyright © TCG 2006-2020

10.2.23.3.6 ASN1PushByte()

```
185 BOOL
186 ASN1PushByte(
187     ASN1MarshalContext          *ctx,
188     BYTE                         b
189 )
190 {
191     if(ctx->offset > 0)
192     {
193         ctx->offset -= 1;
194         if(ctx->buffer)
195             ctx->buffer[ctx->offset] = b;
196         return TRUE;
197     }
198     ctx->offset = -1;
199     return FALSE;
200 }
```

10.2.23.3.7 ASN1PushBytes()

Push some raw bytes onto the buffer. *count* cannot be zero.

Return Value	Meaning
0	count bytes
0	failure unless count was zero

```
201 INT16
202 ASN1PushBytes(
203     ASN1MarshalContext          *ctx,
204     INT16                        count,
205     const BYTE                  *buffer
206 )
207 {
208     // make sure that count is not negative which would mess up the math; and that
209     // if there is a count, there is a buffer
210     VERIFY((count >= 0) && ((buffer != NULL) || (count == 0)));
211     // back up the offset to determine where the new octets will get pushed
212     ctx->offset -= count;
213     // can't go negative
214     VERIFY(ctx->offset >= 0);
215     // if there are buffers, move the data, otherwise, assume that this is just a
216     // test.
217     if(count && buffer && ctx->buffer)
218         MemoryCopy(&ctx->buffer[ctx->offset], buffer, count);
219     return count;
220 Error:
221     ctx->offset = -1;
222     return 0;
223 }
```

10.2.23.3.8 ASN1PushNull()

Return Value	Meaning
0	count bytes
0	failure unless count was zero

```
224 INT16
```

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

```
225 ASN1PushNull(
226     ASN1MarshalContext      *ctx
227 )
228 {
229     ASN1PushByte(ctx, 0);
230     ASN1PushByte(ctx, ASN1_NULL);
231     return (ctx->offset >= 0) ? 2 : 0;
232 }
```

10.2.23.3.9 ASN1PushLength()

Push a length value. This will only handle length values that fit in an INT16.

Return Value	Meaning
0	number of bytes added
0	failure

```
233 INT16
234 ASN1PushLength(
235     ASN1MarshalContext          *ctx,
236     INT16                        len
237 )
238 {
239     UINT16                       start = ctx->offset;
240     VERIFY(len >= 0);
241     if(len <= 127)
242         ASN1PushByte(ctx, (BYTE)len);
243     else
244     {
245         ASN1PushByte(ctx, (BYTE)(len & 0xFF));
246         len >>= 8;
247         if(len == 0)
248             ASN1PushByte(ctx, 0x81);
249         else
250         {
251             ASN1PushByte(ctx, (BYTE)(len));
252             ASN1PushByte(ctx, 0x82);
253         }
254     }
255     goto Exit;
256 Error:
257     ctx->offset = -1;
258 Exit:
259     return (ctx->offset > 0) ? start - ctx->offset : 0;
260 }
```

10.2.23.3.10 ASN1PushTagAndLength()

Return Value	Meaning
0	number of bytes added
0	failure

```
261 INT16
262 ASN1PushTagAndLength(
263     ASN1MarshalContext          *ctx,
264     BYTE                         tag,
265     INT16                        length
266 )
267 {
```

```
268     INT16       bytes;
269     bytes = ASN1PushLength(ctx, length);
270     bytes += (INT16)ASN1PushByte(ctx, tag);
271     return (ctx->offset < 0) ? 0 : bytes;
272 }
```

10.2.23.3.11 ASN1PushTaggedOctetString()

This function will push a random octet string.

Return Value	Meaning
0	number of bytes added
0	failure

```
273 INT16
274 ASN1PushTaggedOctetString(
275     ASN1MarshalContext          *ctx,
276     INT16                        size,
277     const BYTE                  *string,
278     BYTE                         tag
279 )
280 {
281     ASN1PushBytes(ctx, size, string);
282     // PushTagAndLenght just tells how many octets it added so the total size of this
283     // element is the sum of those octets and input size.
284     size += ASN1PushTagAndLength(ctx, tag, size);
285     return size;
286 }
```

10.2.23.3.12 ASN1PushUINT()

This function pushes an native-endian integer value. This just changes a native-endian integer into a big-endian byte string and calls ASN1PushInteger(). That function will remove leading zeros and make sure that the number is positive.

Return Value	Meaning
0	count bytes
0	failure unless count was zero

```
287 INT16
288 ASN1PushUINT(
289     ASN1MarshalContext      *ctx,
290     UINT32                   integer
291 )
292 {
293     BYTE                    marshaled[4];
294     UINT32_TO_BYTE_ARRAY(integer, marshaled);
295     return ASN1PushInteger(ctx, 4, marshaled);
296 }
```

10.2.23.3.13 ASN1PushInteger

Push a big-endian integer on the end of the buffer

 Copyright © TCG 2006-2020

Return Value	Meaning
0	the number of bytes marshaled for the integer
0	failure

```
297     INT16
298     ASN1PushInteger(
299         ASN1MarshalContext  *ctx,           // IN/OUT: buffer context
300         INT16                iLen,          // IN: octets of the integer
301         BYTE                *integer        // IN: big-endian integer
302     )
303     {
304         // no leading 0's
305         while((*integer == 0) && (--iLen > 0))
306             integer++;
307         // Move the bytes to the buffer
308         ASN1PushBytes(ctx, iLen, integer);
309         // if needed, add a leading byte of 0 to make the number positive
310         if(*integer & 0x80)
311             iLen += (INT16)ASN1PushByte(ctx, 0);
312         // PushTagAndLenght just tells how many octets it added so the total size of this
313         // element is the sum of those octets and the adjusted input size.
314         iLen +=  ASN1PushTagAndLength(ctx, ASN1_INTEGER, iLen);
315         return iLen;
316     }
```

10.2.23.3.14 ASN1PushOID()

This function is used to add an OID. An OID is 0x06 followed by a byte of size followed by size bytes. This is used to avoid having to do anything special in the definition of an OID.

Return Value	Meaning
0	the number of bytes marshaled for the integer
0	failure

```
317     INT16
318     ASN1PushOID(
319         ASN1MarshalContext          *ctx,
320         const BYTE                  *OID
321     )
322     {
323         if((*OID == ASN1_OBJECT_IDENTIFIER) && ((OID[1] & 0x80) == 0))
324         {
325             return ASN1PushBytes(ctx, OID[1] + 2, OID);
326         }
327         ctx->offset = -1;
328         return 0;
329     }
```

10.2.24 X509_ECC.c

6  #include "CryptHash_fp.h"
```

10.2.24.2 Functions

10.2.24.2.1 X509PushPoint()

This seems like it might be used more than once so...

Return Value	Meaning
0	number of bytes added
0	failure

```
7   INT16
8   X509PushPoint(
9       ASN1MarshalContext      *ctx,
10      TPMS_ECC_POINT          *p
11  )
12  {
13      // Push a bit string containing the public key. For now, push the x, and y
14      // coordinates of the public point, bottom up
15      ASN1StartMarshalContext(ctx); // BIT STRING
16      {
17          ASN1PushBytes(ctx, p->y.t.size, p->y.t.buffer);
18          ASN1PushBytes(ctx, p->x.t.size, p->x.t.buffer);
19          ASN1PushByte(ctx, 0x04);
20      }
21      return ASN1EndEncapsulation(ctx, ASN1_BITSTRING); // Ends BIT STRING
22  }
```

10.2.24.2.2 X509AddSigningAlgorithmECC()

This creates the singing algorithm data.

Return Value	Meaning
0	number of bytes added
0	failure

```
23  INT16
24  X509AddSigningAlgorithmECC(
25      OBJECT              *signKey,
26      TPMT_SIG_SCHEME     *scheme,
27      ASN1MarshalContext  *ctx
28  )
29  {
30      PHASH_DEF            hashDef = CryptGetHashDef(scheme->details.any.hashAlg);
31  //
32      NOT_REFERENCED(signKey);
```

 Copyright © TCG 2006-2020

```
33      // If the desired hashAlg definition wasn't found...
34      if(hashDef->hashAlg != scheme->details.any.hashAlg)
35          return 0;
36
37      switch(scheme->scheme)
38      {
39          case ALG_ECDSA_VALUE:
40              // Make sure that we have an OID for this hash and ECC
41              if((hashDef->ECDSA)[0] != ASN1_OBJECT_IDENTIFIER)
42                  break;
43              // if this is just an implementation check, indicate that this
44              // combination is supported
45              if(!ctx)
46                  return 1;
47              ASN1StartMarshalContext(ctx);
48              ASN1PushOID(ctx, hashDef->ECDSA);
49              return ASN1EndEncapsulation(ctx, ASN1_CONSTRUCTED_SEQUENCE);
50          default:
51              break;
52      }
53      return 0;
54  }
```

10.2.24.2.3 X509AddPublicECC()

This function will add the *publicKey* description to the DER data. If ctx is NULL, then no data is transferred and this function will indicate if the TPM has the values for DER-encoding of the public key.

Return Value	Meaning
0	number of bytes added
0	failure

```
55  INT16
56  X509AddPublicECC(
57      OBJECT                  *object,
58      ASN1MarshalContext      *ctx
59  )
60  {

10.2.26.2 Unmarshaling Functions

10.2.26.2.1 X509FindExtensionByOID()

This will search a list of X509 extensions to find an extension with the requested OID. If the extension is found, the output context (*ctx*) is set up to point to the OID in the extension.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure (could be catastrophic)

```
16 BOOL
17 X509FindExtensionByOID(
18     ASN1UnmarshalContext    *ctxIn,         // IN: the context to search
19     ASN1UnmarshalContext    *ctx,           // OUT: the extension context
20     const BYTE              *OID            // IN: oid to search for
21 )
22 {
23     INT16                length;
24 //
25     pAssert(ctxIn != NULL);
26     // Make the search non-destructive of the input if ctx provided. Otherwise, use
27     // the provided context.
28     if (ctx == NULL)
29         ctx = ctxIn;
30     // if the provide search context is different from the context of the extension,
31     // then copy the search context to the search context.
32     else if(ctx != ctxIn)
33         *ctx = *ctxIn;
34     // Now, search in the extension context
35     for(;ctx->size > ctx->offset; ctx->offset += length)
36     {
37         VERIFY((length = ASN1NextTag(ctx)) >= 0);
38         // If this is not a constructed sequence, then it doesn't belong
39         // in the extensions.
40         VERIFY(ctx->tag == ASN1_CONSTRUCTED_SEQUENCE);
41         // Make sure that this entry could hold the OID
42         if (length >= OID_SIZE(OID))
43         {
44             // See if this is a match for the provided object identifier.
```

 Copyright © TCG 2006-2020

```
45              if (MemoryEqual(OID, &(ctx->buffer[ctx->offset]), OID_SIZE(OID)))
46              {
47                  // Return with ' ctx' set to point to the start of the OID with the
size
48                  // set to be the size of the SEQUENCE
49                  ctx->buffer += ctx->offset;
50                  ctx->offset = 0;
51                  ctx->size = length;
52                  return TRUE;
53              }
54          }
55      }
56      VERIFY(ctx->offset == ctx->size);
57      return FALSE;

60      ctx->size = -1;
61      return FALSE;
62  }
```

10.2.26.2.2 X509GetExtensionBits()

This function will extract a bit field from an extension. If the extension doesn't contain a bit string, it will fail.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
63  UINT32
64  X509GetExtensionBits(
65      ASN1UnmarshalContext            *ctx,
66      UINT32                          *value
67  )
68  {
69      INT16               length;
70  //
71      while(((length = ASN1NextTag(ctx)) > 0) && (ctx->size > ctx->offset))
72      {
73          // Since this is an extension, the extension value will be in an OCTET STRING
74          if(ctx->tag == ASN1_OCTET_STRING)
75          {
76              return ASN1GetBitStringValue(ctx, value);
77          }
78          ctx->offset += length;
79      }
80      ctx->size = -1;
81      return FALSE;
82  }
```

10.2.26.2.3 X509ProcessExtensions()

This function is used to process the TPMA_OBJECT and KeyUsage() extensions. It is not in the CertifyX509.c code because it makes the code harder to follow.

Error Returns	Meaning
TPM_RCS_ATTRIBUTES	the attributes of object are not consistent with the extension setting
TPM_RC_VALUE	problem parsing the extensions

```
83   TPM_RC
84   X509ProcessExtensions(
85       OBJECT              *object,        // IN: The object with the attributes to
86                                           //      check
87       stringRef           *extension      // IN: The start and length of the extensions
88   )
89   {

13
14  #define NUM_AC  (sizeof(ac) / sizeof(acCapabilities))
15  #endif // 1 The simulated AC data
```

10.2.27.1.1 AcToCapabilities()

This function returns a pointer to a list of AC capabilities.

```
16  TPML_AC_CAPABILITIES *
17  AcToCapabilities(
18      TPMI_RH_AC      component       // IN: component
19  )
20  {
21      UINT32          index;
22  //
23      for(index = 0; index < NUM_AC; index++)
24      {
25          if(ac[index].ac == component)
26              return ac[index].acData;
27      }
28      return NULL;
29  }
```

10.2.27.1.2 AcIsAccessible()

Function to determine if an AC handle references an actual AC

Return Value	Meaning

```
30  BOOL
31  AcIsAccessible(
32      TPM_HANDLE          acHandle
33      )
34  {
35      // In this implementation, the AC exists if there are some capabilities to go
36      // with the handle
37      return AcToCapabilities(acHandle) != NULL;
38  }
```

10.2.27.1.3 AcCapabilitiesGet()

This function returns a list of capabilities associated with an AC

Return Value	Meaning
YES	if there are more handles available
NO	all the available handles has been returned

```
39  TPMI_YES_NO
40  AcCapabilitiesGet(
41      TPMI_RH_AC              component,      // IN: the component
42      TPM_AT                  type,           // IN: start capability type
43      TPML_AC_CAPABILITIES   *capabilityList // OUT: list of handle
44  )
45  {
46      TPMI_YES_NO             more = NO;
47      UINT32                  i;
48      TPML_AC_CAPABILITIES   *capabilities = AcToCapabilities(component);
49
50      pAssert(HandleGetType(component) == TPM_HT_AC);
51
52      // Initialize output handle list
53      capabilityList->count = 0;
54
55      if(capabilities != NULL)
56      {
57          // Find the first capability less than or equal to type
58          for(i = 0; i < capabilities->count; i++)
59          {
60              if(capabilities->acCapabilities[i].tag >= type)
61              {
62                  // copy the capabilities until we run out or fill the list
63                  for(; (capabilityList->count < MAX_AC_CAPABILITIES)
64                      && (i < capabilities->count); i++)
65                  {
66                      capabilityList->acCapabilities[capabilityList->count]
67                          = capabilities->acCapabilities[i];
68                      capabilityList->count++;
69                  }
70                  more = i < capabilities->count;
71              }
72          }
73      }
74      return more;
75  }
```

10.2.27.1.4 AcSendObject()

Stub to handle sending of an AC object

Error Returns	Meaning

```
76  TPM_RC
77  AcSendObject(
78      TPM_HANDLE           acHandle,       // IN: Handle of AC receiving object
79      OBJECT              *object,         // IN: object structure to send
80      TPMS_AC_OUTPUT      *acDataOut       // OUT: results of operation
81  )
82  {
83      NOT_REFERENCED(object);
84      NOT_REFERENCED(acHandle);
85      acDataOut->tag = TPM_AT_ERROR;   // indicate that the response contains an
86                                       // error code
87      acDataOut->data = TPM_AE_NONE;   // but there is no error.
88
```

```
89          return TPM_RC_SUCCESS;
90      }
```

Annex A
(informative)
Implementation Dependent

A.1 Introduction

This header file contains definitions that are used to define a TPM profile. The values are chosen by the manufacturer. The values here are chosen to represent a full featured TPM so that all of the TPM's capabilities can be simulated and tested. This file would change based on the implementation.

The file listed below was generated by an automated tool using three documents as inputs. They are:

1) The TCG_Algorithm Registery,
2) Part 2 of this specification, and
3) A purpose-built document that contains vendor-specific information in tables.

All of the values in this file have #ifdef 'guards' so that they may be defined in a command line.Additionally, TpmBuildSwitches.h allows an additional file to be specified in the compiler command line and preset any of these values.

A.2 TpmProfile.h

```
1  #ifndef _TPM_PROFILE_H_
2  #define _TPM_PROFILE_H_

Annex B
(informative)
Library-Specific

B.1 Introduction

This clause contains the files that are specific to a cryptographic library used by the TPM code.

Three categories are defined for cryptographic functions:

1) big number math (asymmetric cryptography),
2) symmetric ciphers, and
3) hash functions.

The code is structured to make it possible to use different libraries for different categories. For example, one might choose to use OpenSSL for its math library, but use a different library for hashing and symmetric cryptography. Since OpenSSL supports all three categories, it might be more typical to combine libraries of specific functions; that is, one library might only contain block ciphers while another supports big number math.

B.2 OpenSSL-Specific Files

B.2.1. Introduction

The following files are specific to a port that uses the OpenSSL library for cryptographic functions.

B.2.2. Header Files

B.2.2.1. TpmToOsslHash.h

B.2.2.1.1. Introduction

This header file is used to *splice* the OpenSSL hash code into the TPM code.

```
1   #ifndef HASH_LIB_DEFINED
2   #define HASH_LIB_DEFINED
3   #define HASH_LIB_OSSL
4   #include <openssl/evp.h>
5   #include <openssl/sha.h>
6   #include <openssl/sm3.h>
7   #include <openssl/ossl_typ.h>
```

B.2.2.1.2. Links to the OpenSSL HASH code

Redefine the internal name used for each of the hash state structures to the name used by the library. These defines need to be known in all parts of the TPM so that the structure sizes can be properly computed when needed.

```
8   #define tpmHashStateSHA1_t         SHA_CTX
9   #define tpmHashStateSHA256_t       SHA256_CTX
10  #define tpmHashStateSHA384_t       SHA512_CTX
11  #define tpmHashStateSHA512_t       SHA512_CTX
12  #define tpmHashStateSM3_256_t      SM3_CTX
```

The defines below are only needed when compiling CryptHash.c or CryptSmac.c. This isolation is primarily to avoid name space collision. However, if there is a real collision, it will likely show up when the linker tries to put things together.

```
13  #ifdef _CRYPT_HASH_C_
14  typedef BYTE          *PBYTE;
15  typedef const BYTE    *PCBYTE;
```

Define the interface between CryptHash.c to the functions provided by the library. For each method, define the calling parameters of the method and then define how the method is invoked in CryptHash.c.

All hashes are required to have the same calling sequence. If they don't, create a simple adaptation function that converts from the **standard** form of the call to the form used by the specific hash (and then send a nasty letter to the person who wrote the hash function for the library).

The macro that calls the method also defines how the parameters get swizzled between the default form (in CryptHash.c)and the library form.

```
16  #define HASH_ALIGNMENT  RADIX_BYTES
```

Initialize the hash context

```
17  #define HASH_START_METHOD_DEF   void (HASH_START_METHOD)(PANY_HASH_STATE state)
18  #define HASH_START(hashState)                                                  \
19                  ((hashState)->def->method.start)(&(hashState)->state);
```

Add data to the hash

```
20  #define HASH_DATA_METHOD_DEF                                                   \
21                  void (HASH_DATA_METHOD)(PANY_HASH_STATE state,                 \
22                                          PCBYTE buffer,                         \
23                                          size_t size)
24  #define HASH_DATA(hashState, dInSize, dIn)                                     \
25                  ((hashState)->def->method.data)(&(hashState)->state, dIn, dInSize)
```

Finalize the hash and get the digest

```
26  #define HASH_END_METHOD_DEF                                                    \
27                  void (HASH_END_METHOD)(BYTE *buffer, PANY_HASH_STATE state)
28  #define HASH_END(hashState, buffer)                                            \
29                  ((hashState)->def->method.end)(buffer, &(hashState)->state)
```

Copy the hash context

NOTE: For import, export, and copy, memcpy() is used since there is no reformatting necessary between the internal and external forms.

```
30  #define HASH_STATE_COPY_METHOD_DEF                                             \
31                  void (HASH_STATE_COPY_METHOD)(PANY_HASH_STATE to,              \
32                                                PCANY_HASH_STATE from,           \
33                                                size_t size)
34  #define HASH_STATE_COPY(hashStateOut, hashStateIn)                             \
35                  ((hashStateIn)->def->method.copy)(&(hashStateOut)->state,      \
36                                                &(hashStateIn)->state,           \
37                                                (hashStateIn)->def->contextSize)
```

Copy (with reformatting when necessary) an internal hash structure to an external blob

```
38  #define  HASH_STATE_EXPORT_METHOD_DEF                                          \
39                  void (HASH_STATE_EXPORT_METHOD)(BYTE *to,                      \
40                                              PCANY_HASH_STATE from,             \
41                                              size_t size)
42  #define  HASH_STATE_EXPORT(to, hashStateFrom)                                  \

44                          (&(((BYTE *)(to))[offsetof(HASH_STATE, state)]),       \
45                           &(hashStateFrom)->state,                              \
46                           (hashStateFrom)->def->contextSize)
```

Copy from an external blob to an internal formate (with reformatting when necessary

```
47  #define  HASH_STATE_IMPORT_METHOD_DEF                                          \
48                  void (HASH_STATE_IMPORT_METHOD)(PANY_HASH_STATE to,            \
49                                                  const BYTE *from,              \
50                                                   size_t size)
51  #define  HASH_STATE_IMPORT(hashStateTo, from)                                  \
52                  ((hashStateTo)->def->method.copyIn)                            \
53                          (&(hashStateTo)->state,                                \
54                           &(((const BYTE *)(from))[offsetof(HASH_STATE, state)]),\
55                           (hashStateTo)->def->contextSize)
```

Function aliases. The code in CryptHash.c uses the internal designation for the functions. These need to be translated to the function names of the library.

```
56  #define tpmHashStart_SHA1           SHA1_Init   // external name of the
57                                                  // initialization method
```

```
58   #define tpmHashData_SHA1              SHA1_Update

83   #define tpmHashEnd_SM3_256            sm3_final
84   #define tpmHashStateCopy_SM3_256      memcpy
85   #define tpmHashStateExport_SM3_256    memcpy
86   #define tpmHashStateImport_SM3_256    memcpy
87   #endif // _CRYPT_HASH_C_
88   #define LibHashInit()
```

This definition would change if there were something to report

```
89   #define HashLibSimulationEnd()
90   #endif // HASH_LIB_DEFINED
```

B.2.2.2. TpmToOsslMath.h

B.2.2.2.1. Introduction

This file contains the structure definitions used for ECC in the LibTomCrypt() version of the code. These definitions would change, based on the library. The ECC-related structures that cross the TPM interface are defined in TpmTypes.h

```
1   #ifndef MATH_LIB_DEFINED
2   #define MATH_LIB_DEFINED
3   #define MATH_LIB_OSSL
4   #include <openssl/evp.h>
5   #include <openssl/ec.h>
6   #if OPENSSL_VERSION_NUMBER >= 0x10200000L
7       // Check the bignum_st definition in crypto/bn/bn_lcl.h and either update the
8       // version check or provide the new definition for this version.
9   #   error Untested OpenSSL version
10  #elif OPENSSL_VERSION_NUMBER >= 0x10100000L
11      // from crypto/bn/bn_lcl.h
12      struct bignum_st {
13          BN_ULONG *d;                /* Pointer to an array of 'BN_BITS2' bit
14                                      * chunks. */
15          int top;                    /* Index of last used d +1. */
16                                      /* The next are internal book keeping for
bn_expand. */
17          int dmax;                   /* Size of the d array. */
18          int neg;                    /* one if the number is negative */
19          int flags;
20      };
21  #endif // OPENSSL_VERSION_NUMBER
22  #include <openssl/bn.h>
```

B.2.2.2.2. Macros and Defines

Make sure that the library is using the correct size for a crypt word

```
23  #if    defined THIRTY_TWO_BIT && (RADIX_BITS != 32)   \
24      || ((defined SIXTY_FOUR_BIT_LONG || defined SIXTY_FOUR_BIT) \
25          && (RADIX_BITS != 64))
26  #   error Ossl library is using different radix
27  #endif
```

Allocate a local BIGNUM value. For the allocation, a *bigNum* structure is created as is a local BIGNUM. The *bigNum* is initialized and then the BIGNUM is set to reference the local value.

```
28  #define BIG_VAR(name, bits)                                         \
29      BN_VAR(name##Bn, (bits));                                       \
30      BIGNUM          _##name;                                        \
31      BIGNUM          *name = BigInitialized(&_##name,                \
32                                  BnInit(name##Bn,                    \
33                                  BYTES_TO_CRYPT_WORDS(sizeof(_##name##Bn.d))))
```

Allocate a BIGNUM and initialize with the values in a *bigNum* initializer

```
34  #define BIG_INITIALIZED(name, initializer)                      \
35      BIGNUM           _##name;                                   \
36      BIGNUM          *name = BigInitialized(&_##name, initializer)
37  typedef struct
38  {
39      const ECC_CURVE_DATA    *C;     // the TPM curve values
40      EC_GROUP                *G;     // group parameters
```

```
41      BN_CTX                  *CTX;   // the context for the math (this might not be
42                                      // the context in which the curve was created>;
43  } OSSL_CURVE_DATA;
44  typedef OSSL_CURVE_DATA      *bigCurve;
45  #define AccessCurveData(E)      ((E)->C)
46  #include "TpmToOsslSupport_fp.h"
```

Start and end a context within which the OpenSSL memory management works

```
47  #define OSSL_ENTER()     BN_CTX          *CTX = OsslContextEnter()
48  #define OSSL_LEAVE()     OsslContextLeave(CTX)
```

Start and end a context that spans multiple ECC functions. This is used so that the group for the curve can persist across multiple frames.

```
49  #define CURVE_INITIALIZED(name, initializer)                        \
50      OSSL_CURVE_DATA      _##name;                                   \
51      bigCurve             name =  BnCurveInitialize(&_##name, initializer)
52  #define CURVE_FREE(name)               BnCurveFree(name)
```

Start and end a local stack frame within the context of the curve frame

```
53  #define ECC_ENTER()      BN_CTX          *CTX = OsslPushContext(E->CTX)
54  #define ECC_LEAVE()      OsslPopContext(CTX)
55  #define BN_NEW()         BnNewVariable(CTX)
```

This definition would change if there were something to report

```
56  #define MathLibSimulationEnd()
57  #endif // MATH_LIB_DEFINED
```

 Copyright © TCG 2006-2020

B.2.2.3. TpmToOsslSym.h

B.2.2.3.1. Introduction

This header file is used to *splice* the OpenSSL library into the TPM code.

The support required of a library are a hash module, a block cipher module and portions of a big number library. All of the library-dependent headers should have the same guard to that only the first one gets defined.

```
1   #ifndef SYM_LIB_DEFINED
2   #define SYM_LIB_DEFINED
3   #define SYM_LIB_OSSL
4   #include <openssl/aes.h>
5   #include <openssl/des.h>
6   #include <openssl/sm4.h>
7   #include <openssl/camellia.h>
8   #include <openssl/bn.h>
9   #include <openssl/ossl_typ.h>
```

B.2.2.3.2. Links to the OpenSSL symmetric algorithms

The Crypt functions that call the block encryption function use the parameters in the order:

a) *keySchedule*

b) in buffer

c) out buffer Since open SSL uses the order in *encryptoCall_t* above, need to swizzle the values to the order required by the library.

```
10  #define SWIZZLE(keySchedule, in, out)                                          \
11      (const BYTE *)(in), (BYTE *)(out), (void *)(keySchedule)
```

Define the order of parameters to the library functions that do block encryption and decryption.

```
12  typedef void(*TpmCryptSetSymKeyCall_t)(
13      const BYTE  *in,
14      BYTE        *out,
15      void *keySchedule
16      );
17  #define SYM_ALIGNMENT   RADIX_BYTES
```

B.2.2.3.3. Links to the OpenSSL AES code

Macros to set up the encryption/decryption key schedules

AES:

```
18  #define TpmCryptSetEncryptKeyAES(key, keySizeInBits, schedule)                 \
19      AES_set_encrypt_key((key), (keySizeInBits), (tpmKeyScheduleAES *)(schedule))
20  #define TpmCryptSetDecryptKeyAES(key, keySizeInBits, schedule)                 \
21      AES_set_decrypt_key((key), (keySizeInBits), (tpmKeyScheduleAES *)(schedule))
```

Macros to alias encryption calls to specific algorithms. This should be used sparingly. Currently, only used by CryptSym.c and CryptRand.c

When using these calls, to call the AES block encryption code, the caller should use: TpmCryptEncryptAES(SWIZZLE(*keySchedule*, in, out));

```
22    #define TpmCryptEncryptAES            AES_encrypt
23    #define TpmCryptDecryptAES            AES_decrypt
24    #define tpmKeyScheduleAES             AES_KEY
```

B.2.2.3.4. Links to the OpenSSL DES code

```
25    #if ALG_TDES
26    #include "TpmToOsslDesSupport_fp.h"
27    #endif
28    #define TpmCryptSetEncryptKeyTDES(key, keySizeInBits, schedule)                      \
29        TDES_set_encrypt_key((key), (keySizeInBits), (tpmKeyScheduleTDES *)(schedule))
30    #define TpmCryptSetDecryptKeyTDES(key, keySizeInBits, schedule)                      \
31        TDES_set_encrypt_key((key), (keySizeInBits), (tpmKeyScheduleTDES *)(schedule))
```

Macros to alias encryption calls to specific algorithms. This should be used sparingly. Currently, only used by CryptRand.c

```
32    #define TpmCryptEncryptTDES           TDES_encrypt
33    #define TpmCryptDecryptTDES           TDES_decrypt
34    #define tpmKeyScheduleTDES            DES_key_schedule
```

B.2.2.3.5. Links to the OpenSSL SM4 code

Macros to set up the encryption/decryption key schedules

```
35    #define TpmCryptSetEncryptKeySM4(key, keySizeInBits, schedule)                       \
36        SM4_set_key((key), (tpmKeyScheduleSM4 *)(schedule))
37    #define TpmCryptSetDecryptKeySM4(key, keySizeInBits, schedule)                       \
38        SM4_set_key((key), (tpmKeyScheduleSM4 *)(schedule))
```

Macros to alias encryption calls to specific algorithms. This should be used sparingly.

```
39    #define TpmCryptEncryptSM4            SM4_encrypt
40    #define TpmCryptDecryptSM4            SM4_decrypt
41    #define tpmKeyScheduleSM4             SM4_KEY
```

B.2.2.3.6. Links to the OpenSSL CAMELLIA code

Macros to set up the encryption/decryption key schedules

```
42    #define TpmCryptSetEncryptKeyCAMELLIA(key, keySizeInBits, schedule)                  \
43        Camellia_set_key((key), (keySizeInBits), (tpmKeyScheduleCAMELLIA *)(schedule))
44    #define TpmCryptSetDecryptKeyCAMELLIA(key, keySizeInBits, schedule)                  \
45        Camellia_set_key((key), (keySizeInBits), (tpmKeyScheduleCAMELLIA *)(schedule))
```

Macros to alias encryption calls to specific algorithms. This should be used sparingly.

```
46    #define TpmCryptEncryptCAMELLIA            Camellia_encrypt
47    #define TpmCryptDecryptCAMELLIA            Camellia_decrypt
48    #define tpmKeyScheduleCAMELLIA             CAMELLIA_KEY
```

Forward reference

```
49    typedef union tpmCryptKeySchedule_t tpmCryptKeySchedule_t;
```

This definition would change if there were something to report

```
50    #define SymLibSimulationEnd()
51    #endif // SYM_LIB_DEFINED
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

B.2.3. Source Files

B.2.3.1. TpmToOsslDesSupport.c

B.2.3.1.1. Introduction

The functions in this file are used for initialization of the interface to the OpenSSL library.

B.2.3.1.2. Defines and Includes

```
1   #include "Tpm.h"
2   #if (defined SYM_LIB_OSSL) && ALG_TDES
```

B.2.3.1.3. Functions

B.2.3.1.3.1. TDES_set_encyrpt_key()

This function makes creation of a TDES key look like the creation of a key for any of the other OpenSSL block ciphers. It will create three key schedules, one for each of the DES keys. If there are only two keys, then the third schedule is a copy of the first.

```
3   void
4   TDES_set_encrypt_key(
5       const BYTE                    *key,
6       UINT16                         keySizeInBits,
7       tpmKeyScheduleTDES            *keySchedule
8       )
9   {
10      DES_set_key_unchecked((const DES_cblock *)key, &keySchedule[0]);
11      DES_set_key_unchecked((const DES_cblock *)&key[8], &keySchedule[1]);
12      // If is two-key, copy the schedule for K1 into K3, otherwise, compute the
13      // the schedule for K3
14      if(keySizeInBits == 128)
15          keySchedule[2] = keySchedule[0];
16      else
17          DES_set_key_unchecked((const DES_cblock *)&key[16],
18                                &keySchedule[2]);
19  }
```

B.2.3.1.3.2. TDES_encyrpt()

The TPM code uses one key schedule. For TDES, the schedule contains three schedules. OpenSSL wants the schedules referenced separately. This function does that.

```
20  void TDES_encrypt(
21      const BYTE                *in,
22      BYTE                      *out,
23      tpmKeyScheduleTDES        *ks
24      )
25  {
26      DES_ecb3_encrypt((const DES_cblock *)in, (DES_cblock *)out,
27                       &ks[0], &ks[1], &ks[2],
28                       DES_ENCRYPT);
29  }
```

 Copyright © TCG 2006-2020

B.2.3.1.3.3. TDES_decrypt()

As with TDES_encypt() this function bridges between the TPM single schedule model and the OpenSSL three schedule model.

```
30  void TDES_decrypt(
31      const BYTE          *in,
32      BYTE                *out,
33      tpmKeyScheduleTDES   *ks
34      )
35  {
36      DES_ecb3_encrypt((const_DES_cblock *)in, (DES_cblock *)out,
37                       &ks[0], &ks[1], &ks[2],
38                       DES_DECRYPT);
39  }
40  #endif // SYM_LIB_OSSL
```

B.2.3.2. TpmToOsslMath.c

B.2.3.2.1. Introduction

The functions in this file provide the low-level interface between the TPM code and the big number and elliptic curve math routines in OpenSSL.

Most math on big numbers require a context. The context contains the memory in which OpenSSL creates and manages the big number values. When a OpenSSL math function will be called that modifies a BIGNUM value, that value must be created in an OpenSSL context. The first line of code in such a function must be: OSSL_ENTER(); and the last operation before returning must be OSSL_LEAVE(). OpenSSL variables can then be created with BnNewVariable(). Constant values to be used by OpenSSL are created from the *bigNum* values passed to the functions in this file. Space for the BIGNUM control block is allocated in the stack of the function and then it is initialized by calling BigInitialized(). That function sets up the values in the BIGNUM structure and sets the data pointer to point to the data in the bignum_t. This is only used when the value is known to be a constant in the called function.

Because the allocations of constants is on the local stack and the OSSL_ENTER()/OSSL_LEAVE() pair flushes everything created in OpenSSL memory, there should be no chance of a memory leak.

B.2.3.2.2. Includes and Defines

```
1  #include "Tpm.h"
2  #ifdef MATH_LIB_OSSL
3  #include "TpmToOsslMath_fp.h"
```

B.2.3.2.3. Functions

B.2.3.2.3.1. OsslToTpmBn()

This function converts an OpenSSL BIGNUM to a TPM bignum. In this implementation it is assumed that OpenSSL uses a different control structure but the same data layout -- an array of native-endian words in little-endian order.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure because value will not fit or OpenSSL variable doesn't exist

```
4  BOOL
5  OsslToTpmBn(
6      bigNum          bn,
7      BIGNUM          *osslBn
8      )
9  {
10     VERIFY(osslBn != NULL);
11     // If the bn is NULL, it means that an output value pointer was NULL meaning that
12     // the results is simply to be discarded.
13     if(bn != NULL)
14     {
15         int         i;
16     //
17         VERIFY((unsigned)osslBn->top <= BnGetAllocated(bn));
18         for(i = 0; i < osslBn->top; i++)
19             bn->d[i] = osslBn->d[i];
20         BnSetTop(bn, osslBn->top);
21     }
22     return TRUE;
```

 Copyright © TCG 2006-2020

```
23  Error:
24      return FALSE;
25  }
```

B.2.3.2.3.2. BigInitialized()

This function initializes an OSSL BIGNUM from a TPM *bigConst*. Do not use this for values that are passed to OpenSLL when they are not declared as const in the function prototype. Instead, use BnNewVariable().

```
26  BIGNUM *
27  BigInitialized(
28      BIGNUM              *toInit,
29      bigConst             initializer
30      )
31  {
32      if(initializer == NULL)
33          FAIL(FATAL_ERROR_PARAMETER);
34      if(toInit == NULL || initializer == NULL)
35          return NULL;
36      toInit->d = (BN_ULONG *)&initializer->d[0];
37      toInit->dmax = (int)initializer->allocated;
38      toInit->top = (int)initializer->size;
39      toInit->neg = 0;
40      toInit->flags = 0;
41      return toInit;
42  }
43  #ifndef OSSL_DEBUG
44  #   define BIGNUM_PRINT(label, bn, eol)
45  #   define DEBUG_PRINT(x)
46  #else
47  #   define DEBUG_PRINT(x)   printf("%s", x)
48  #   define BIGNUM_PRINT(label, bn, eol) BIGNUM_print((label), (bn), (eol))
```

B.2.3.2.3.3. BIGNUM_print()

```
49  static void
50  BIGNUM_print(
51      const char      *label,
52      const BIGNUM    *a,
53      BOOL             eol
54      )
55  {
56      BN_ULONG        *d;
57      int              i;
58      int              notZero = FALSE;
59
60      if(label != NULL)
61          printf("%s", label);
62      if(a == NULL)
63      {
64          printf("NULL");
65          goto done;
66      }
67      if (a->neg)
68          printf("-");
69      for(i = a->top, d = &a->d[i - 1]; i > 0; i--)
70      {
71          int         j;
72          BN_ULONG    l = *d--;
73          for(j = BN_BITS2 - 8; j >= 0; j -= 8)
74          {
75              BYTE    b = (BYTE)((l >> j) & 0xFF);
```

```
76                notZero = notZero || (b != 0);
77                if(notZero)
78                    printf("%02x", b);
79            }
80            if(!notZero)
81                printf("0");
82        }
83    done:
84        if(eol)
85            printf("\n");
86        return;
87    }
88    #endif
```

B.2.3.2.3.4. BnNewVariable()

This function allocates a new variable in the provided context. If the context does not exist or the allocation fails, it is a catastrophic failure.

```
89    static BIGNUM *
90    BnNewVariable(
91        BN_CTX          *CTX
92    )
93    {
94        BIGNUM          *new;
95    //
96        // This check is intended to protect against calling this function without
97        // having initialized the CTX.
98        if((CTX == NULL) || ((new = BN_CTX_get(CTX)) == NULL))
99            FAIL(FATAL_ERROR_ALLOCATION);
100       return new;
101   }
102   #if LIBRARY_COMPATIBILITY_CHECK
```

B.2.3.2.3.5. MathLibraryCompatibilityCheck()

```
103   BOOL
104   MathLibraryCompatibilityCheck(
105       void
106       )
107   {

B.2.3.2.3.6. BnModMult()

This function does a modular multiply. It first does a multiply and then a divide and returns the remainder of the divide.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
131 LIB_EXPORT BOOL
132 BnModMult(
133     bigNum              result,
134     bigConst            op1,
135     bigConst            op2,
136     bigConst            modulus
137     )
138 {
139     OSSL_ENTER();
140     BOOL                OK = TRUE;
141     BIGNUM              *bnResult = BN_NEW();
142     BIGNUM              *bnTemp = BN_NEW();
143     BIG_INITIALIZED(bnOp1, op1);
144     BIG_INITIALIZED(bnOp2, op2);
145     BIG_INITIALIZED(bnMod, modulus);
146 //
147     VERIFY(BN_mul(bnTemp, bnOp1, bnOp2, CTX));
148     VERIFY(BN_div(NULL, bnResult, bnTemp, bnMod, CTX));
149     VERIFY(OsslToTpmBn(result, bnResult));
150     goto Exit;
151 Error:
152     OK = FALSE;
153 Exit:
154     OSSL_LEAVE();
155     return OK;
156 }
```

B.2.3.2.3.7. BnMult()

Multiplies two numbers

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
157 LIB_EXPORT BOOL
158 BnMult(
159     bigNum               result,
160     bigConst             multiplicand,
161     bigConst             multiplier
162     )
163 {
164     OSSL_ENTER();
165     BIGNUM              *bnTemp = BN_NEW();
166     BOOL                 OK = TRUE;
167     BIG_INITIALIZED(bnA, multiplicand);
168     BIG_INITIALIZED(bnB, multiplier);
169 //
```

```
170         VERIFY(BN_mul(bnTemp, bnA, bnB, CTX));
171         VERIFY(OsslToTpmBn(result, bnTemp));
172         goto Exit;
173     Error:
174         OK = FALSE;
175     Exit:
176         OSSL_LEAVE();
177         return OK;
178     }
```

B.2.3.2.3.8. BnDiv()

This function divides two *bigNum* values. The function returns FALSE if there is an error in the operation.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
179     LIB_EXPORT BOOL
180     BnDiv(
181         bigNum                 quotient,
182         bigNum                 remainder,
183         bigConst               dividend,
184         bigConst               divisor
185         )
186     {
187         OSSL_ENTER();
188         BIGNUM                *bnQ = BN_NEW();

190         BOOL                   OK = TRUE;
191         BIG_INITIALIZED(bnDend, dividend);
192         BIG_INITIALIZED(bnSor, divisor);
193     //
194         if(BnEqualZero(divisor))
195             FAIL(FATAL_ERROR_DIVIDE_ZERO);
196         VERIFY(BN_div(bnQ, bnR, bnDend, bnSor, CTX));
197         VERIFY(OsslToTpmBn(quotient, bnQ));
198         VERIFY(OsslToTpmBn(remainder, bnR));
199         DEBUG_PRINT("In BnDiv:\n");
200         BIGNUM_PRINT("   bnDividend: ", bnDend, TRUE);
201         BIGNUM_PRINT("    bnDivisor: ", bnSor, TRUE);
202         BIGNUM_PRINT("   bnQuotient: ", bnQ, TRUE);
203         BIGNUM_PRINT("  bnRemainder: ", bnR, TRUE);
204         goto Exit;
205     Error:
206         OK = FALSE;
207     Exit:
208         OSSL_LEAVE();
209         return OK;
210     }
211     #if ALG_RSA
```

B.2.3.2.3.9. BnGcd()

Get the greatest common divisor of two numbers

 Copyright © TCG 2006-2020

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
212 LIB_EXPORT BOOL
213 BnGcd(
214     bigNum      gcd,            // OUT: the common divisor
215     bigConst    number1,        // IN:
216     bigConst    number2         // IN:
217     )
218 {
219     OSSL_ENTER();
220     BIGNUM              *bnGcd = BN_NEW();
221     BOOL                 OK = TRUE;
222     BIG_INITIALIZED(bn1, number1);
223     BIG_INITIALIZED(bn2, number2);
224 //
225     VERIFY(BN_gcd(bnGcd, bn1, bn2, CTX));
226     VERIFY(OsslToTpmBn(gcd, bnGcd));
227     goto Exit;
228 Error:
229     OK = FALSE;
230 Exit:
231     OSSL_LEAVE();
232     return OK;
233 }
```

B.2.3.2.3.10. BnModExp()

Do modular exponentiation using *bigNum* values. The conversion from a bignum_t to a *bigNum* is trivial as they are based on the same structure

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
234 LIB_EXPORT BOOL
235 BnModExp(
236     bigNum               result,         // OUT: the result
237     bigConst             number,         // IN: number to exponentiate
238     bigConst             exponent,       // IN:
239     bigConst             modulus         // IN:
240     )
241 {
242     OSSL_ENTER();
243     BIGNUM              *bnResult = BN_NEW();
244     BOOL                 OK = TRUE;
245     BIG_INITIALIZED(bnN, number);
246     BIG_INITIALIZED(bnE, exponent);
247     BIG_INITIALIZED(bnM, modulus);
248 //
249     VERIFY(BN_mod_exp(bnResult, bnN, bnE, bnM, CTX));
250     VERIFY(OsslToTpmBn(result, bnResult));
251     goto Exit;
252 Error:
253     OK = FALSE;
254 Exit:
255     OSSL_LEAVE();
256     return OK;
257 }
```

 Copyright © TCG 2006-2020

B.2.3.2.3.11. BnModInverse()

Modular multiplicative inverse

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
258  LIB_EXPORT BOOL
259  BnModInverse(
260      bigNum              result,
261      bigConst            number,
262      bigConst            modulus
263      )
264  {
265      OSSL_ENTER();
266      BIGNUM             *bnResult = BN_NEW();
267      BOOL               OK = TRUE;
268      BIG_INITIALIZED(bnN, number);
269      BIG_INITIALIZED(bnM, modulus);
270  //
271      VERIFY(BN_mod_inverse(bnResult, bnN, bnM, CTX) != NULL);
272      VERIFY(OsslToTpmBn(result, bnResult));
273      goto Exit;
274  Error:
275      OK = FALSE;
276  Exit:
277      OSSL_LEAVE();
278      return OK;
279  }
280  #endif // ALG_RSA
281  #if ALG_ECC
```

B.2.3.2.3.12. PointFromOssl()

Function to copy the point result from an OSSL function to a *bigNum*

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation

```
282  static BOOL
283  PointFromOssl(
284      bigPoint          pOut,      // OUT: resulting point
285      EC_POINT         *pIn,       // IN: the point to return
286      bigCurve          E          // IN: the curve
287      )
288  {
289      BIGNUM          *x = NULL;
290      BIGNUM          *y = NULL;
291      BOOL             OK;
292      BN_CTX_start(E->CTX);
293  //
294      x = BN_CTX_get(E->CTX);
295      y = BN_CTX_get(E->CTX);
296
297      if(y == NULL)
298          FAIL(FATAL_ERROR_ALLOCATION);
299      // If this returns false, then the point is at infinity
300      OK = EC_POINT_get_affine_coordinates(E->G, pIn, x, y, E->CTX);
```

 Copyright © TCG 2006-2020

```
301     if(OK)
302     {
303         OsslToTpmBn(pOut->x, x);
304         OsslToTpmBn(pOut->y, y);
305         BnSetWord(pOut->z, 1);
306     }
307     else
308         BnSetWord(pOut->z, 0);
309     BN_CTX_end(E->CTX);
310     return OK;
311 }
```

B.2.3.2.3.13. EcPointInitialized()

Allocate and initialize a point.

```
312 static EC_POINT *
313 EcPointInitialized(
314     pointConst          initializer,
315     bigCurve            E
316     )
317 {
318     EC_POINT            *P = NULL;
319
320     if(initializer != NULL)
321     {
322         BIG_INITIALIZED(bnX, initializer->x);
323         BIG_INITIALIZED(bnY, initializer->y);
324         P = EC_POINT_new(E->G);
325         if(E == NULL)
326             FAIL(FATAL_ERROR_ALLOCATION);
327         if(!EC_POINT_set_affine_coordinates(E->G, P, bnX, bnY, E->CTX))
328             P = NULL;
329     }
330     return P;
331 }
```

B.2.3.2.3.14. BnCurveInitialize()

This function initializes the OpenSSL curve information structure. This structure points to the TPM-defined values for the curve, to the context for the number values in the frame, and to the OpenSSL-defined group values.

Return Value	Meaning
NULL	the TPM_ECC_CURVE is not valid or there was a problem in in initializing the curve data
non-NULL	points to *E*

```
332 LIB_EXPORT bigCurve
333 BnCurveInitialize(
334     bigCurve          E,            // IN: curve structure to initialize
335     TPM_ECC_CURVE     curveId       // IN: curve identifier
336 )
337 {
338     const ECC_CURVE_DATA    *C = GetCurveData(curveId);
339     if(C == NULL)
340         E = NULL;
341     if(E != NULL)
342     {
343         // This creates the OpenSSL memory context that stays in effect as long as the
344         // curve (E) is defined.
```

```
345         OSSL_ENTER();                          // if the allocation fails, the TPM fails
346         EC_POINT                 *P = NULL;
347         BIG_INITIALIZED(bnP, C->prime);
348         BIG_INITIALIZED(bnA, C->a);
349         BIG_INITIALIZED(bnB, C->b);
350         BIG_INITIALIZED(bnX, C->base.x);
351         BIG_INITIALIZED(bnY, C->base.y);
352         BIG_INITIALIZED(bnN, C->order);
353         BIG_INITIALIZED(bnH, C->h);
354     //
355         E->C = C;
356         E->CTX = CTX;
357
358         // initialize EC group, associate a generator point and initialize the point
359         // from the parameter data
360         // Create a group structure
361         E->G = EC_GROUP_new_curve_GFp(bnP, bnA, bnB, CTX);
362         VERIFY(E->G != NULL);
363
364         // Allocate a point in the group that will be used in setting the
365         // generator. This is not needed after the generator is set.
366         P = EC_POINT_new(E->G);
367         VERIFY(P != NULL);
368
369         // Need to use this in case Montgomery method is being used
370         VERIFY(EC_POINT_set_affine_coordinates(E->G, P, bnX, bnY, CTX));
371         // Now set the generator
372         VERIFY(EC_GROUP_set_generator(E->G, P, bnN, bnH));
373
374         EC_POINT_free(P);
375         goto Exit;
376 Error:
377         EC_POINT_free(P);
378         BnCurveFree(E);
379         E = NULL;
380     }
381 Exit:
382     return E;
383 }
```

B.2.3.2.3.15. BnCurveFree()

This function will free the allocated components of the curve and end the frame in which the curve data exists

```
384 LIB_EXPORT void
385 BnCurveFree(
386     bigCurve                     E
387 )
388 {
389     if(E)
390     {
391         EC_GROUP_free(E->G);
392         OsslContextLeave(E->CTX);
393     }
394 }
```

B.2.3.2.3.16. BnEccModMult()

This function does a point multiply of the form R = [d]S

Copyright © TCG 2006-2020

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation; treat as result being point at infinity

```
395 LIB_EXPORT BOOL
396 BnEccModMult(
397     bigPoint            R,          // OUT: computed point
398     pointConst          S,          // IN: point to multiply by 'd' (optional)
399     bigConst            d,          // IN: scalar for [d]S
400     bigCurve            E
401     )
402 {
403     EC_POINT           *pR = EC_POINT_new(E->G);
404     EC_POINT           *pS = EcPointInitialized(S, E);
405     BIG_INITIALIZED(bnD, d);
406
407     if(S == NULL)
408         EC_POINT_mul(E->G, pR, bnD, NULL, NULL, E->CTX);
409     else
410         EC_POINT_mul(E->G, pR, NULL, pS, bnD, E->CTX);
411     PointFromOssl(R, pR, E);
412     EC_POINT_free(pR);
413     EC_POINT_free(pS);
414     return !BnEqualZero(R->z);
415 }
```

B.2.3.2.3.17. BnEccModMult2()

This function does a point multiply of the form R = [d]G + [u]Q

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation; treat as result being point at infinity

```
416 LIB_EXPORT BOOL
417 BnEccModMult2(
418     bigPoint            R,          // OUT: computed point

438         points[0] = pS;
439         points[1] = pQ;
440         scalars[0] = bnD;
441         scalars[1] = bnU;
```

```
442             EC_POINTs_mul(E->G, pR, NULL, 2, points, scalars, E->CTX);
443         }
444         PointFromOssl(R, pR, E);
445         EC_POINT_free(pR);
446         EC_POINT_free(pS);
447         EC_POINT_free(pQ);
448         return !BnEqualZero(R->z);
449     }
```

B.2.3.2.4. BnEccAdd()

This function does addition of two points.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure in operation; treat as result being point at infinity

```
450     LIB_EXPORT BOOL
451     BnEccAdd(
452         bigPoint             R,          // OUT: computed point
453         pointConst           S,          // IN: point to multiply by 'd'
454         pointConst           Q,          // IN: second point
455         bigCurve             E           // IN: curve
456         )
457     {
458         EC_POINT            *pR = EC_POINT_new(E->G);
459         EC_POINT            *pS = EcPointInitialized(S, E);
460         EC_POINT            *pQ = EcPointInitialized(Q, E);
461     //
462         EC_POINT_add(E->G, pR, pS, pQ, E->CTX);
463
464         PointFromOssl(R, pR, E);
465         EC_POINT_free(pR);
466         EC_POINT_free(pS);
467         EC_POINT_free(pQ);
468         return !BnEqualZero(R->z);
469     }
470     #endif // ALG_ECC
471     #endif // MATHLIB OSSL
```

B.2.3.3. TpmToOsslSupport.c

B.2.3.3.1. Introduction

The functions in this file are used for initialization of the interface to the OpenSSL library.

B.2.3.3.2. Defines and Includes

```
1    #include "Tpm.h"
2    #if defined(HASH_LIB_OSSL) || defined(MATH_LIB_OSSL) || defined(SYM_LIB_OSSL)
```

Used to pass the pointers to the correct sub-keys

```
3    typedef const BYTE *desKeyPointers[3];
```

B.2.3.3.2.1. SupportLibInit()

This does any initialization required by the support library.

```
4    LIB_EXPORT int
5    SupportLibInit(
6        void
7        )
8    {
9        return TRUE;
10   }
```

B.2.3.3.2.2. OsslContextEnter()

This function is used to initialize an OpenSSL context at the start of a function that will call to an OpenSSL math function.

```
11   BN_CTX *
12   OsslContextEnter(
13       void
14       )
15   {
16       BN_CTX              *CTX = BN_CTX_new();
17   //
18       return OsslPushContext(CTX);
19   }
```

B.2.3.3.2.3. OsslContextLeave()

This is the companion function to OsslContextEnter().

```
20   void
21   OsslContextLeave(
22       BN_CTX          *CTX
23       )
24   {
25       OsslPopContext(CTX);
26       BN_CTX_free(CTX);
27   }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

B.2.3.3.2.4. OsslPushContext()

This function is used to create a frame in a context. All values allocated within this context after the frame is started will be automatically freed when the context (OsslPopContext()

```
28  BN_CTX *
29  OsslPushContext(
30      BN_CTX          *CTX
31      )
32  {
33      if(CTX == NULL)
34          FAIL(FATAL_ERROR_ALLOCATION);
35      BN_CTX_start(CTX);
36      return CTX;
37  }
```

B.2.3.3.2.5. OsslPopContext()

This is the companion function to OsslPushContext().

```
38  void
39  OsslPopContext(
40      BN_CTX          *CTX
41      )
42  {
43      // BN_CTX_end can't be called with NULL. It will blow up.
44      if(CTX != NULL)
45          BN_CTX_end(CTX);
46  }
47  #endif // HASH_LIB_OSSL || MATH_LIB_OSSL || SYM_LIB_OSSL
```

Annex C
(informative)
Simulation Environment

C.1 Introduction

These files are used to simulate some of the implementation-dependent hardware of a TPM. These files are provided to allow creation of a simulation environment for the TPM. These files are not expected to be part of a hardware TPM implementation.

C.2 Cancel.c

C.2.1. Description

This module simulates the cancel pins on the TPM.

C.2.2. Includes, Typedefs, Structures, and Defines

```
1   #include "Platform.h"
```

C.2.3. Functions

C.2.3.1. _plat__IsCanceled()

Check if the cancel flag is set

Return Value	Meaning
TRUE(1)	if cancel flag is set
FALSE(0)	if cancel flag is not set

```
2   LIB_EXPORT int
3   _plat__IsCanceled(
4       void
5       )
6   {
7       // return cancel flag
8       return s_isCanceled;
9   }
```

C.2.3.2. _plat__SetCancel()

Set cancel flag.

```
10  LIB_EXPORT void
11  _plat__SetCancel(
12      void
13      )
14  {
15      s_isCanceled = TRUE;
16      return;
17  }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

C.2.3.3. _plat__ClearCancel()

Clear cancel flag

```
18  LIB_EXPORT void
19  _plat__ClearCancel(
20      void
21      )
22  {
23      s_isCanceled = FALSE;
24      return;
25  }
```

C.3 Clock.c

C.3.1. Description

This file contains the routines that are used by the simulator to mimic a hardware clock on a TPM.

In this implementation, all the time values are measured in millisecond. However, the precision of the clock functions may be implementation dependent.

C.3.2. Includes and Data Definitions

```
1   #include <assert.h>
2   #include "Platform.h"
3   #include "TpmFail_fp.h"
```

C.3.3. Simulator Functions

C.3.3.1. Introduction

This set of functions is intended to be called by the simulator environment in order to simulate hardware events.

C.3.3.2. _plat__TimerReset()

This function sets current system clock time as t0 for counting TPM time. This function is called at a power on event to reset the clock. When the clock is reset, the indication that the clock was stopped is also set.

```
4   LIB_EXPORT void
5   _plat__TimerReset(
6       void
7       )
8   {
9       s_lastSystemTime = 0;
10      s_tpmTime = 0;
11      s_adjustRate = CLOCK_NOMINAL;
12      s_timerReset = TRUE;
13      s_timerStopped = TRUE;
14      return;
15  }
```

C.3.3.3. _plat__TimerRestart()

This function should be called in order to simulate the restart of the timer should it be stopped while power is still applied.

```
16  LIB_EXPORT void
17  _plat__TimerRestart(
18      void
19      )
20  {
21      s_timerStopped = TRUE;
22      return;
23  }
```

C.3.4. Functions Used by TPM

C.3.4.1. Introduction

These functions are called by the TPM code. They should be replaced by appropriated hardware functions.

```
24  #include <time.h>
25  clock_t     debugTime;
26
27  //*** _plat__RealTime()
28  // This is another, probably futile, attempt to define a portable function
29  // that will return a 64-bit clock value that has mSec resolution.
30  LIB_EXPORT uint64_t
31  _plat__RealTime(
32      void
33  )
34  {
35      clock64_t           time;
36  #ifdef _MSC_VER
37      struct _timeb       sysTime;
38  //
39      _ftime_s(&sysTime);
40      time = (clock64_t)(sysTime.time) * 1000 + sysTime.millitm;
41      // set the time back by one hour if daylight savings
42      if(sysTime.dstflag)
43          time -= 1000 * 60 * 60;  // mSec/sec * sec/min * min/hour = ms/hour
44  #else
45      // hopefully, this will work with most UNIX systems
46      struct timespec     systime;
47  //
48      clock_gettime(CLOCK_MONOTONIC, &systime);
49      time = (clock64_t)systime.tv_sec * 1000 + (systime.tv_nsec / 1000000);
50  #endif
51      return time;
52  }
```

C.3.4.2. _plat__TimerRead()

This function provides access to the tick timer of the platform. The TPM code uses this value to drive the TPM Clock.

The tick timer is supposed to run when power is applied to the device. This timer should not be reset by time events including _TPM_Init(). It should only be reset when TPM power is re-applied.

If the TPM is run in a protected environment, that environment may provide the tick time to the TPM as long as the time provided by the environment is not allowed to go backwards. If the time provided by the system can go backwards during a power discontinuity, then the _plat__Signal_PowerOn() should call _plat__TimerReset().

```
53  LIB_EXPORT uint64_t
54  _plat__TimerRead(
55      void
56      )
57  {
58  #ifdef HARDWARE_CLOCK
59  #error      "need a defintion for reading the hardware clock"
60      return HARDWARE_CLOCK
61  #else
62      clock64_t          timeDiff;
63      clock64_t          adjustedTimeDiff;
64      clock64_t          timeNow;
```

 Copyright © TCG 2006-2020

```
65      clock64_t          readjustedTimeDiff;
66
67      // This produces a timeNow that is basically locked to the system clock.
68      timeNow = _plat__RealTime();
69
70      // if this hasn't been initialized, initialize it
71      if(s_lastSystemTime == 0)
72      {
73          s_lastSystemTime = timeNow;
74          debugTime = clock();
75          s_lastReportedTime = 0;
76          s_realTimePrevious = 0;
77      }
78      // The system time can bounce around and that's OK as long as we don't allow
79      // time to go backwards. When the time does appear to go backwards, set
80      // lastSystemTime to be the new value and then update the reported time.
81      if(timeNow < s_lastReportedTime)
82          s_lastSystemTime = timeNow;
83      s_lastReportedTime = s_lastReportedTime + timeNow - s_lastSystemTime;
84      s_lastSystemTime = timeNow;
85      timeNow = s_lastReportedTime;
86
87      // The code above produces a timeNow that is similar to the value returned
88      // by Clock(). The difference is that timeNow does not max out, and it is
89      // at a ms. rate rather than at a CLOCKS_PER_SEC rate. The code below
90      // uses that value and does the rate adjustment on the time value.
91      // If there is no difference in time, then skip all the computations
92      if(s_realTimePrevious >= timeNow)
93          return s_tpmTime;
94      // Compute the amount of time since the last update of the system clock
95      timeDiff = timeNow - s_realTimePrevious;
96
97      // Do the time rate adjustment and conversion from CLOCKS_PER_SEC to mSec
98      adjustedTimeDiff = (timeDiff * CLOCK_NOMINAL) / ((uint64_t)s_adjustRate);
99
100     // update the TPM time with the adjusted timeDiff
101     s_tpmTime += (clock64_t)adjustedTimeDiff;
102
103     // Might have some rounding error that would loose CLOCKS. See what is not
104     // being used. As mentioned above, this could result in putting back more than
105     // is taken out. Here, we are trying to recreate timeDiff.
106     readjustedTimeDiff = (adjustedTimeDiff * (uint64_t)s_adjustRate )
107                                 / CLOCK_NOMINAL;
108
109     // adjusted is now converted back to being the amount we should advance the
110     // previous sampled time. It should always be less than or equal to timeDiff.
111     // That is, we could not have use more time than we started with.
112     s_realTimePrevious = s_realTimePrevious + readjustedTimeDiff;
113
114 #ifdef  DEBUGGING_TIME
115     // Put this in so that TPM time will pass much faster than real time when
116     // doing debug.
117     // A value of 1000 for DEBUG_TIME_MULTIPLER will make each ms into a second
118     // A good value might be 100
119     return (s_tpmTime * DEBUG_TIME_MULTIPLIER);
120 #endif
121     return s_tpmTime;
122 #endif
123 }
```

C.3.4.3. _plat__TimerWasReset()

This function is used to interrogate the flag indicating if the tick timer has been reset.

If the *resetFlag* parameter is SET, then the flag will be CLEAR before the function returns.

 Copyright © TCG 2006-2020

```
124 LIB_EXPORT int
125 _plat__TimerWasReset(
126    void
127     )
128 {
129     int           retVal = s_timerReset;
130     s_timerReset = FALSE;
131     return retVal;
132 }
```

C.3.4.4. _plat__TimerWasStopped()

This function is used to interrogate the flag indicating if the tick timer has been stopped. If so, this is typically a reason to roll the nonce.

This function will CLEAR the *s_timerStopped* flag before returning. This provides functionality that is similar to status register that is cleared when read. This is the model used here because it is the one that has the most impact on the TPM code as the flag can only be accessed by one entity in the TPM. Any other implementation of the hardware can be made to look like a read-once register.

```
133 LIB_EXPORT int
134 _plat__TimerWasStopped(
135     void
136     )
137 {
138     int           retVal = s_timerStopped;
139     s_timerStopped = FALSE;
140     return retVal;
141 }
```

C.3.4.5. _plat__ClockAdjustRate()

Adjust the clock rate

```
142 LIB_EXPORT void
143 _plat__ClockAdjustRate(
144     int                adjust         // IN: the adjust number.  It could be positive
145                                       //     or negative
146     )
147 {
148     // We expect the caller should only use a fixed set of constant values to
149     // adjust the rate
150     switch(adjust)
151     {
152         case CLOCK_ADJUST_COARSE:
153             s_adjustRate += CLOCK_ADJUST_COARSE;
154             break;
155         case -CLOCK_ADJUST_COARSE:
156             s_adjustRate -= CLOCK_ADJUST_COARSE;
157             break;
158         case CLOCK_ADJUST_MEDIUM:
159             s_adjustRate += CLOCK_ADJUST_MEDIUM;
160             break;
161         case -CLOCK_ADJUST_MEDIUM:
162             s_adjustRate -= CLOCK_ADJUST_MEDIUM;
163             break;
164         case CLOCK_ADJUST_FINE:
165             s_adjustRate += CLOCK_ADJUST_FINE;
166             break;
167         case -CLOCK_ADJUST_FINE:
168             s_adjustRate -= CLOCK_ADJUST_FINE;
169             break;
```

 Copyright © TCG 2006-2020

```
170             default:
171                 // ignore any other values;
172                 break;
173         }
174
175         if(s_adjustRate > (CLOCK_NOMINAL + CLOCK_ADJUST_LIMIT))
176             s_adjustRate = CLOCK_NOMINAL + CLOCK_ADJUST_LIMIT;
177         if(s_adjustRate < (CLOCK_NOMINAL - CLOCK_ADJUST_LIMIT))
178             s_adjustRate = CLOCK_NOMINAL - CLOCK_ADJUST_LIMIT;
179
180         return;
181     }
```

C.4 Entropy.c

C.4.1. Includes and Local Values

```
1   #define _CRT_RAND_S
2   #include <stdlib.h>
3   #include <memory.h>
4   #include <time.h>
5   #include "Platform.h"
6   #ifdef _MSC_VER
7   #include <process.h>
8   #else
9   #include <unistd.h>
10  #endif
```

This is the last 32-bits of hardware entropy produced. We have to check to see that two consecutive 32-bit values are not the same because (according to FIPS 140-2, annex C

"If each call to a RNG produces blocks of n bits (where n > 15), the first n-bit block generated after power-up, initialization, or reset shall not be used, but shall be saved for comparison with the next n-bit block to be generated. Each subsequent generation of an n-bit block shall be compared with the previously generated block. The test shall fail if any two compared n-bit blocks are equal."

```
11  extern uint32_t        lastEntropy;
12
13  //** Functions
14
15  //*** rand32()
16  // Local function to get a 32-bit random number
17  static uint32_t
18  rand32(
19      void
20  )
21  {
22      uint32_t    rndNum = rand();
23  #if RAND_MAX < UINT16_MAX
24      // If the maximum value of the random number is a 15-bit number, then shift it up
25      // 15 bits, get 15 more bits, shift that up 2 and then XOR in another value to get
26      // a full 32 bits.
27      rndNum = (rndNum << 15) ^ rand();
28      rndNum = (rndNum << 2) ^ rand();
29  #elif RAND_MAX == UINT16_MAX
30      // If the maximum size is 16-bits, shift it and add another 16 bits
31      rndNum = (rndNum << 16) ^ rand();
32  #elif RAND_MAX < UINT32_MAX
33      // If 31 bits, then shift 1 and include another random value to get the extra bit
34      rndNum = (rndNum << 1) ^ rand();
35  #endif
36      return rndNum;
37  }
```

C.4.1.1. _plat__GetEntropy()

This function is used to get available hardware entropy. In a hardware implementation of this function, there would be no call to the system to get entropy.

 Copyright © TCG 2006-2020

Return Value	Meaning
0	hardware failure of the entropy generator, this is sticky
0	the returned amount of entropy (bytes)

```
38 LIB_EXPORT int32_t
39 _plat__GetEntropy(
40     unsigned char        *entropy,           // output buffer
41     uint32_t              amount             // amount requested
42 )
43 {
44     uint32_t             rndNum;
45     int32_t              ret;
46 //
47     if(amount == 0)
48     {
49         // Seed the platform entropy source if the entropy source is software. There
50         // is no reason to put a guard macro (#if or #ifdef) around this code because
51         // this code would not be here if someone was changing it for a system with
52         // actual hardware.
53         //
54         // NOTE 1: The following command does not provide proper cryptographic
55         // entropy. Its primary purpose to make sure that different instances of the
56         // simulator, possibly started by a script on the same machine, are seeded
57         // differently. Vendors of the actual TPMs need to ensure availability of
58         // proper entropy using their platform-specific means.
59         //
60         // NOTE 2: In debug builds by default the reference implementation will seed
61         // its RNG deterministically (without using any platform provided randomness).
62         // See the USE_DEBUG_RNG macro and DRBG_GetEntropy() function.
63 #ifdef _MSC_VER
64         srand((unsigned)_plat__RealTime() ^ _getpid());
65 #else
66         srand((unsigned)_plat__RealTime() ^ getpid());
67 #endif
68         lastEntropy = rand32();
69         ret = 0;
70     }
71     else
72     {
73         rndNum = rand32();
74         if(rndNum == lastEntropy)
75         {
76             ret = -1;
77         }
78         else
79         {
80             lastEntropy = rndNum;
81             // Each process will have its random number generator initialized
82             // according to the process id and the initialization time. This is not a
83             // lot of entropy so, to add a bit more, XOR the current time value into
84             // the returned entropy value.
85             // NOTE: the reason for including the time here rather than have it in
86             // in the value assigned to lastEntropy is that rand() could be broken and
87             // using the time would in the lastEntropy value would hide this.
88             rndNum ^= (uint32_t)_plat__RealTime();
89
90             // Only provide entropy 32 bits at a time to test the ability
91             // of the caller to deal with partial results.
92             ret = MIN(amount, sizeof(rndNum));
93             memcpy(entropy, &rndNum, ret);
94         }
95     }
96     return ret;
```

```

C.5 LocalityPlat.c

C.5.1. Includes

```
1   #include "Platform.h"
```

C.5.2. Functions

C.5.2.1. _plat__LocalityGet()

Get the most recent command locality in locality value form. This is an integer value for locality and not a locality structure The locality can be 0-4 or 32-255. 5-31 is not allowed.

```
2   LIB_EXPORT unsigned char
3   _plat__LocalityGet(
4       void
5       )
6   {
7       return s_locality;
8   }
```

C.5.2.2. _plat__LocalitySet()

Set the most recent command locality in locality value form

```
9   LIB_EXPORT void
10  _plat__LocalitySet(
11      unsigned char    locality
12      )
13  {
14      if(locality > 4 && locality < 32)
15          locality = 0;
16      s_locality = locality;
17      return;
18  }
```

C.6 NVMem.c

C.6.1. Description

This file contains the NV read and write access methods. This implementation uses RAM/file and does not manage the RAM/file as NV blocks. The implementation may become more sophisticated over time.

C.6.2. Includes and Local

```
1  #include <memory.h>
2  #include <string.h>
3  #include <assert.h>
4  #include "Platform.h"
5  #if FILE_BACKED_NV
6  #   include          <stdio.h>
7  FILE                  *s_NvFile = NULL;
8  int                    s_NeedsManufacture = FALSE;
9  #endif
10
11 //**Functions
12
13 #if FILE_BACKED_NV
14
15 //*** NvFileOpen()
16 // This function opens the file used to hold the NV image.
17 //  Return Type: int
18 //  >= 0        success
19 //  -1          error
20 static int
21 NvFileOpen(
22     const char       *mode
23 )
24 {
25 #if defined(NV_FILE_PATH)
26 #   define TO_STRING(s) TO_STRING_IMPL(s)
27 #   define TO_STRING_IMPL(s) #s
28     const char* s_NvFilePath = TO_STRING(NV_FILE_PATH);
29 #   undef TO_STRING
30 #   undef TO_STRING_IMPL
31 #else
32     const char* s_NvFilePath = "NVChip";
33 #endif
34
35     // Try to open an exist NVChip file for read/write
36 #   if defined _MSC_VER && 1
37     if(fopen_s(&s_NvFile, s_NvFilePath, mode) != 0)
38         s_NvFile = NULL;
39 #   else
40     s_NvFile = fopen(s_NvFilePath, mode);
41 #   endif
42     return (s_NvFile == NULL) ? -1 : 0;
43 }
```

C.6.2.1. NvFileCommit()

Write all of the contents of the NV image to a file.

Return Value	Meaning
TRUE(1)	success
FALSE(0)	failure

```
44  static int
45  NvFileCommit(
46      void
47  )
48  {
49      int          OK;
50      // If NV file is not available, return failure
51      if(s_NvFile == NULL)
52          return 1;
53      // Write RAM data to NV
54      fseek(s_NvFile, 0, SEEK_SET);
55      OK = (NV_MEMORY_SIZE == fwrite(s_NV, 1, NV_MEMORY_SIZE, s_NvFile));
56      OK = OK && (0 == fflush(s_NvFile));
57      assert(OK);
58      return OK;
59  }
```

C.6.2.2. NvFileSize()

This function gets the size of the NV file and puts the file pointer were desired using the seek method values. SEEK_SET => beginning; SEEK_CUR => current position and SEEK_END => to the end of the file.

```
60  static long
61  NvFileSize(
62      int          leaveAt
63  )
64  {
65      long     fileSize;
66      long     filePos = ftell(s_NvFile);
67  //
68      assert(NULL != s_NvFile);
69
70      fseek(s_NvFile, 0, SEEK_END);
71      fileSize = ftell(s_NvFile);
72      switch(leaveAt)
73      {
74          case SEEK_SET:
75              filePos = 0;
76          case SEEK_CUR:
77              fseek(s_NvFile, filePos, SEEK_SET);
78              break;
79          case SEEK_END:
80              break;
81          default:
82              assert(FALSE);
83              break;
84      }
85      return fileSize;
86  }
87  #endif
```

C.6.2.3. _plat__NvErrors()

This function is used by the simulator to set the error flags in the NV subsystem to simulate an error in the NV loading process

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
88  LIB_EXPORT void
89  _plat__NvErrors(
90      int                 recoverable,
91      int                 unrecoverable
92      )
93  {
94      s_NV_unrecoverable = unrecoverable;
95      s_NV_recoverable = recoverable;
96  }
```

C.6.2.4. _plat__NVEnable()

Enable NV memory.

This version just pulls in data from a file. In a real TPM, with NV on chip, this function would verify the integrity of the saved context. If the NV memory was not on chip but was in something like RPMB, the NV state would be read in, decrypted and integrity checked.

The recovery from an integrity failure depends on where the error occurred. It it was in the state that is discarded by TPM Reset, then the error is recoverable if the TPM is reset. Otherwise, the TPM must go into failure mode.

Return Value	Meaning
0	if success
0	if receive recoverable error
<0	if unrecoverable error

```
97  LIB_EXPORT int
98  _plat__NVEnable(
99      void                *platParameter  // IN: platform specific parameters
100     )
101 {
102     NOT_REFERENCED(platParameter);          // to keep compiler quiet
103 //
104     // Start assuming everything is OK
105     s_NV_unrecoverable = FALSE;
106     s_NV_recoverable = FALSE;
107 #if FILE_BACKED_NV
108     if(s_NvFile != NULL)
109         return 0;
110     // Initialize all the bytes in the ram copy of the NV
111     _plat__NvMemoryClear(0, NV_MEMORY_SIZE);
112
113     // If the file exists
114     if(NvFileOpen("r+b") >= 0)
115     {
116         long    fileSize = NvFileSize(SEEK_SET);    // get the file size and leave the
117                                                     // file pointer at the start
118 //
119         // If the size is right, read the data
120         if (NV_MEMORY_SIZE == fileSize)
121         {
122             s_NeedsManufacture =
123                 fread(s_NV, 1, NV_MEMORY_SIZE, s_NvFile) != NV_MEMORY_SIZE;
124         }
125         else
126         {
127             NvFileCommit();     // for any other size, initialize it
128             s_NeedsManufacture = TRUE;
129         }
130     }
```

```
131         // If NVChip file does not exist, try to create it for read/write.
132         else if(NvFileOpen("w+b") >= 0)
133         {
134             NvFileCommit();              // Initialize the file
135             s_NeedsManufacture = TRUE;
136         }
137         assert(NULL != s_NvFile);        // Just in case we are broken for some reason.
138     #endif
139         // NV contents have been initialized and the error checks have been performed. For
140         // simulation purposes, use the signaling interface to indicate if an error is
141         // to be simulated and the type of the error.
142         if(s_NV_unrecoverable)
143             return -1;
144         return s_NV_recoverable;
145     }
```

C.6.2.5. _plat__NVDisable()

Disable NV memory

```
146     LIB_EXPORT void
147     _plat__NVDisable(
148         int                 delete           // IN: If TRUE, delete the NV contents.
149         )
150     {
151     #if  FILE_BACKED_NV
152         if(NULL != s_NvFile)
153         {
154             fclose(s_NvFile);    // Close NV file
155             // Alternative to deleting the file is to set its size to 0. This will not
156             // match the NV size so the TPM will need to be remanufactured.
157             if(delete)
158             {
159                 // Open for writing at the start. Sets the size to zero.
160                 if(NvFileOpen("w") >= 0)
161                 {
162                     fflush(s_NvFile);
163                     fclose(s_NvFile);
164                 }
165             }
166         }
167         s_NvFile = NULL;        // Set file handle to NULL
168     #endif
169         return;
170     }
```

C.6.2.6. _plat__IsNvAvailable()

Check if NV is available

Return Value	Meaning
0	NV is available
1	NV is not available due to write failure
2	NV is not available due to rate limit

```
171     LIB_EXPORT int
172     _plat__IsNvAvailable(
173         void
174         )
175     {
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
176     int         retVal = 0;
177     // NV is not available if the TPM is in failure mode
178     if(!s_NvIsAvailable)
179         retVal = 1;
180 #if FILE_BACKED_NV
181     else
182         retVal = (s_NvFile == NULL);
183 #endif
184     return retVal;
185 }
```

C.6.2.7. _plat__NvMemoryRead()

Function: Read a chunk of NV memory

```
186 LIB_EXPORT void
187 _plat__NvMemoryRead(
188     unsigned int     startOffset,    // IN: read start
189     unsigned int     size,           // IN: size of bytes to read
190     void            *data            // OUT: data buffer
191     )
192 {
193     assert(startOffset + size <= NV_MEMORY_SIZE);
194     memcpy(data, &s_NV[startOffset], size);      // Copy data from RAM
195     return;
196 }
```

C.6.2.8. _plat__NvIsDifferent()

This function checks to see if the NV is different from the test value. This is so that NV will not be written if it has not changed.

Return Value	Meaning
TRUE(1)	the NV location is different from the test value
FALSE(0)	the NV location is the same as the test value

```
197 LIB_EXPORT int
198 _plat__NvIsDifferent(
199     unsigned int     startOffset,    // IN: read start
200     unsigned int     size,           // IN: size of bytes to read
201     void            *data            // IN: data buffer
202     )
203 {
204     return (memcmp(&s_NV[startOffset], data, size) != 0);
205 }
```

C.6.2.9. _plat__NvMemoryWrite()

This function is used to update NV memory. The **write** is to a memory copy of NV. At the end of the current command, any changes are written to the actual NV memory.

NOTE: A useful optimization would be for this code to compare the current contents of NV with the local copy and note the blocks that have changed. Then only write those blocks when _plat__NvCommit() is called.

```
206 LIB_EXPORT int
207 _plat__NvMemoryWrite(
208     unsigned int     startOffset,    // IN: write start
209     unsigned int     size,           // IN: size of bytes to write
210     void            *data            // OUT: data buffer
```

 Copyright © TCG 2006-2020

```
211         )
212     {
213         if(startOffset + size <= NV_MEMORY_SIZE)
214         {
215             memcpy(&s_NV[startOffset], data, size);     // Copy the data to the NV image
216             return TRUE;
217         }
218         return FALSE;
219     }
```

C.6.2.10. _plat__NvMemoryClear()

Function is used to set a range of NV memory bytes to an implementation-dependent value. The value represents the erase state of the memory.

```
220     LIB_EXPORT void
221     _plat__NvMemoryClear(
222         unsigned int     start,          // IN: clear start
223         unsigned int     size            // IN: number of bytes to clear
224         )
225     {
226         assert(start + size <= NV_MEMORY_SIZE);
227         // In this implementation, assume that the erase value for NV is all 1s
228         memset(&s_NV[start], 0xff, size);
229     }
```

C.6.2.11. _plat__NvMemoryMove()

Function: Move a chunk of NV memory from source to destination This function should ensure that if there overlap, the original data is copied before it is written

```
230     LIB_EXPORT void
231     _plat__NvMemoryMove(
232         unsigned int     sourceOffset,   // IN: source offset
233         unsigned int     destOffset,     // IN: destination offset
234         unsigned int     size            // IN: size of data being moved
235         )
236     {
237         assert(sourceOffset + size <= NV_MEMORY_SIZE);
238         assert(destOffset + size <= NV_MEMORY_SIZE);
239         memmove(&s_NV[destOffset], &s_NV[sourceOffset], size);      // Move data in RAM
240         return;
241     }
```

C.6.2.12. _plat__NvCommit()

This function writes the local copy of NV to NV for permanent store. It will write NV_MEMORY_SIZE bytes to NV. If a file is use, the entire file is written.

Return Value	Meaning
0	NV write success
non-0	NV write fail

```
242     LIB_EXPORT int
243     _plat__NvCommit(
244         void
245         )
246     {
247     #if FILE_BACKED_NV
```

```
248         return (NvFileCommit() ? 0 : 1);
249     #else
250         return 0;
251     #endif
252     }
```

C.6.2.13. _plat__SetNvAvail()

Set the current NV state to available. This function is for testing purpose only. It is not part of the platform NV logic

```
253     LIB_EXPORT void
254     _plat__SetNvAvail(
255         void
256         )
257     {
258         s_NvIsAvailable = TRUE;
259         return;
260     }
```

C.6.2.14. _plat__ClearNvAvail()

Set the current NV state to unavailable. This function is for testing purpose only. It is not part of the platform NV logic

```
261     LIB_EXPORT void
262     _plat__ClearNvAvail(
263         void
264         )
265     {
266         s_NvIsAvailable = FALSE;
267         return;
268     }
```

C.6.2.15. _plat__NVNeedsManufacture()

This function is used by the simulator to determine when the TPM's NV state needs to be manufactured.

```
269     LIB_EXPORT int
270     _plat__NVNeedsManufacture(
271         void
272         )
273     {
274     #if FILE_BACKED_NV
275         return s_NeedsManufacture;
276     #else
277         return FALSE;
278     #endif
279     }
```

C.7 PowerPlat.c

C.7.1. Includes and Function Prototypes

```
1  #include     "Platform.h"
2  #include     "_TPM_Init_fp.h"
```

C.7.2. Functions

C.7.2.1. _plat__Signal_PowerOn()

Signal platform power on

```
3  LIB_EXPORT int
4  _plat__Signal_PowerOn(
5      void
6      )
7  {
8      // Reset the timer
9      _plat__TimerReset();
10
11    // Need to indicate that we lost power
12     s_powerLost = TRUE;
13
14     return 0;
15 }
```

C.7.2.2. _plat__WasPowerLost()

Test whether power was lost before a _TPM_Init().

This function will clear the **hardware** indication of power loss before return. This means that there can only be one spot in the TPM code where this value gets read. This method is used here as it is the most difficult to manage in the TPM code and, if the hardware actually works this way, it is hard to make it look like anything else. So, the burden is placed on the TPM code rather than the platform code

Return Value	Meaning
TRUE(1)	power was lost
FALSE(0)	power was not lost

```
16 LIB_EXPORT int
17 _plat__WasPowerLost(
18     void
19     )
20 {
21     int          retVal = s_powerLost;
22     s_powerLost = FALSE;
23     return retVal;
24 }
```

C.7.2.3. _plat_Signal_Reset()

This a TPM reset without a power loss.

```
25 LIB_EXPORT int
26 _plat__Signal_Reset(
```

 Copyright © TCG 2006-2020

```
27      void
28      )
29  {
30      // Initialize locality
31      s_locality = 0;
32
33      // Command cancel
34      s_isCanceled = FALSE;
35
36      _TPM_Init();
37
38      // if we are doing reset but did not have a power failure, then we should
39      // not need to reload NV ...
40
41      return 0;
42  }
```

C.7.2.4. _plat__Signal_PowerOff()

Signal platform power off

```
43  LIB_EXPORT void
44  _plat__Signal_PowerOff(
45      void
46      )
47  {
48      // Prepare NV memory for power off

C.9 PlatformData.c

C.9.1. Description

This file will instance the TPM variables that are not stack allocated. The descriptions for these variables are in Global.h for this project.

C.9.2. Includes

```
1   #define _PLATFORM_DATA_C_
2   #include    "Platform.h"
```

 Copyright © TCG 2006-2020

C.10 PPPlat.c

C.10.1. Description

This module simulates the physical presence interface pins on the TPM.

C.10.2. Includes

```
1    #include "Platform.h"
```

C.10.3. Functions

C.10.3.1. _plat__PhysicalPresenceAsserted()

Check if physical presence is signaled

Return Value	Meaning
TRUE(1)	if physical presence is signaled
FALSE(0)	if physical presence is not signaled

```
2    LIB_EXPORT int
3    _plat__PhysicalPresenceAsserted(
4        void
5        )
6    {
7        // Do not know how to check physical presence without real hardware.
8        // so always return TRUE;
9        return s_physicalPresence;
10   }
```

C.10.3.2. _plat__Signal_PhysicalPresenceOn()

Signal physical presence on

```
11   LIB_EXPORT void
12   _plat__Signal_PhysicalPresenceOn(
13       void
14       )
15   {
16       s_physicalPresence = TRUE;
17       return;
18   }
```

C.10.3.3. _plat__Signal_PhysicalPresenceOff()

Signal physical presence off

```
19   LIB_EXPORT void
20   _plat__Signal_PhysicalPresenceOff(
21       void
22       )
23   {
24       s_physicalPresence = FALSE;
25       return;
26   }
```

C.11 RunCommand.c

C.11.1. Introduction

This module provides the platform specific entry and fail processing. The _plat__RunCommand() function is used to call to ExecuteCommand() in the TPM code. This function does whatever processing is necessary to set up the platform in anticipation of the call to the TPM including setup for error processing.

The _plat__Fail() function is called when there is a failure in the TPM. The TPM code will have set the flag to indicate that the TPM is in failure mode. This call will then recursively call ExecuteCommand() in order to build the failure mode response. When ExecuteCommand() returns to _plat__Fail(), the platform will do some platform specif operation to return to the environment in which the TPM is executing. For a simulator, setjmp/longjmp is used. For an OS, a system exit to the OS would be appropriate.

C.11.2. Includes and locals

```
1   #include "Platform.h"
2   #include <setjmp.h>
3   #include "ExecCommand_fp.h"
4   jmp_buf             s_jumpBuffer;
5
6   //** Functions
7
8   //***_plat__RunCommand()
9   // This version of RunCommand will set up a jum_buf and call ExecuteCommand(). If
10  // the command executes without failing, it will return and RunCommand will return.
11  // If there is a failure in the command, then _plat__Fail() is called and it will
12  // longjump back to RunCommand which will call ExecuteCommand again. However, this
13  // time, the TPM will be in failure mode so ExecuteCommand will simply build
14  // a failure response and return.
15  LIB_EXPORT void
16  _plat__RunCommand(
17      uint32_t         requestSize,    // IN: command buffer size
18      unsigned char   *request,        // IN: command buffer
19      uint32_t        *responseSize,   // IN/OUT: response buffer size
20      unsigned char   **response       // IN/OUT: response buffer
21      )
22  {
23      setjmp(s_jumpBuffer);
24      ExecuteCommand(requestSize, request, responseSize, response);
25  }
```

C.11.2.1. _plat__Fail()

This is the platform depended failure exit for the TPM.

```
26  LIB_EXPORT NORETURN void
27  _plat__Fail(
28      void
29      )
30  {
31      longjmp(&s_jumpBuffer[0], 1);
32  }
```

C.12 Unique.c

C.12.1. Introduction

In some implementations of the TPM, the hardware can provide a secret value to the TPM. This secret value is statistically unique to the instance of the TPM. Typical uses of this value are to provide personalization to the random number generation and as a shared secret between the TPM and the manufacturer.

C.12.2. Includes

```
1  #include "Platform.h"
2  const char notReallyUnique[] =
3  "This is not really a unique value. A real unique value should"
4  " be generated by the platform.";
5
6  //** _plat__GetUnique()
7  // This function is used to access the platform-specific unique value.
8  // This function places the unique value in the provided buffer ('b')
9  // and returns the number of bytes transferred. The function will not
10 // copy more data than 'bSize'.
11 // NOTE: If a platform unique value has unequal distribution of uniqueness
12 // and 'bSize' is smaller than the size of the unique value, the 'bSize'
13 // portion with the most uniqueness should be returned.
14 LIB_EXPORT uint32_t
15 _plat__GetUnique(
16     uint32_t             which,          // authorities (0) or details
17     uint32_t             bSize,          // size of the buffer
18     unsigned char       *b               // output buffer
19     )
20 {
21     const char          *from = notReallyUnique;
22     uint32_t             retVal = 0;
23
24     if(which == 0) // the authorities value
25     {
26         for(retVal = 0;
27         *from != 0 && retVal < bSize;
28             retVal++)
29         {
30             *b++ = *from++;
31         }
32     }
33     else
34     {
35 #define uSize  sizeof(notReallyUnique)
36         b = &b[((bSize < uSize) ? bSize : uSize) - 1];
37         for(retVal = 0;
38         *from != 0 && retVal < bSize;
39             retVal++)
40         {
41             *b-- = *from++;
42         }
43     }
44     return retVal;
45 }
```

C.13 DebugHelpers.c

C.13.1. Description

This file contains the NV read and write access methods. This implementation uses RAM/file and does not manage the RAM/file as NV blocks. The implementation may become more sophisticated over time.

C.13.2. Includes and Local

```
1   #include <stdio.h>
2   #include <time.h>
3   #include "Platform.h"
4   #if CERTIFYX509_DEBUG
5   FILE                *fDebug = NULL;
6   const char          *debugFileName = "DebugFile.txt";
7
8   static FILE *
9   fileOpen(
10      const char        *fn,
11      const char        *mode
12  )
13  {
14      FILE         *f;
15  #   if defined _MSC_VER
16      if(fopen_s(&f, fn, mode) != 0)
17          f = NULL;
18  #   else
19      f = fopen(fn, "w");
20  #   endif
21      return f;
22  }
```

C.13.2.1. DebugFileOpen()

This function opens the file used to hold the debug data.

Return Value	Meaning
0	success
0	error

```
23  int
24  DebugFileOpen(
25      void
26  )
27  {
28      time_t                  t = time(NULL);
29  //
30      // Get current date and time.
31  #   if defined _MSC_VER
32      char                 timeString[100];
33      ctime_s(timeString, (size_t)sizeof(timeString), &t);
34  #   else
35      char                *timeString;
36      timeString = ctime(&t);
37  #   endif
38      // Try to open the debug file
39      fDebug = fileOpen(debugFileName, "w");
40      if(fDebug)
41      {
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

```
42          fprintf(fDebug, "%s\n", timeString);
43          fclose(fDebug);
44          return 0;
45      }
46      return -1;
47  }
```

C.13.2.2. DebugFileClose()

```
48  void
49  DebugFileClose(
50      void
51  )
52  {
53      if(fDebug)
54          fclose(fDebug);
55  }
```

C.13.2.3. DebugDumpBuffer()

```
56  void
57  DebugDumpBuffer(
58      int                size,
59      unsigned char      *buf,
60      const char         *identifier
61  )
62  {
63      int                i;
64  //
65      FILE *f = fileOpen(debugFileName, "a");
66      if(!f)
67          return;
68      if(identifier)
69          fprintf(fDebug, "%s\n", identifier);
70      if(buf)
71      {
72          for(i = 0; i < size; i++)
73          {
74              if(((i % 16) == 0) && (i))
75                  fprintf(fDebug, "\n");
76              fprintf(fDebug, " %02X", buf[i]);
77          }
78          if((size % 16) != 0)
79              fprintf(fDebug, "\n");
80      }
81      fclose(f);
82  }
83  #endif // CERTIFYX509_DEBUG
```

C.16.2. Functions

C.16.2.1. ActSignal()

Function called when there is an ACT event to signal or unsignal

```
2   static void
3   ActSignal(
4       P_ACT_DATA          actData,
5       int                 on
6   )
7   {
8       if(actData == NULL)
9           return;
10      // If this is to turn a signal on, don't do anything if it is already on. If this
11      // is to turn the signal off, do it anyway because this might be for
12      // initialization.
13      if(on && (actData->signaled == TRUE))
14          return;
15      actData->signaled = (uint8_t)on;
16
17      // If there is an action, then replace the "Do something" with the correct action.
18      // It should test 'on' to see if it is turning the signal on or off.
19      switch(actData->number)
20      {
21  #if RH_ACT_0
22          case 0: // Do something
23              return;

83              case 0xF: // Do something
84                  return;
85  #endif
86              default:
87                  return;
88      }
89  }
```

C.16.2.2. ActGetDataPointer()

```
90  static P_ACT_DATA
91  ActGetDataPointer(
92      uint32_t            act
93  )
94  {
95
96  #define RETURN_ACT_POINTER(N)  if(0x##N == act) return &ACT_##N;
97
98      FOR_EACH_ACT(RETURN_ACT_POINTER)
99
100     return (P_ACT_DATA)NULL;
101 }
```

C.16.2.3. _plat__ACT_GetImplemented()

This function tests to see if an ACT is implemented. It is a belt and suspenders function because the TPM should not be calling to to manipulate an ACT that is not implemented. However, this could help the simulator code which doesn't necessarily know if an ACT is implemented or not.

```
102 LIB_EXPORT int
103 _plat__ACT_GetImplemented(
104     uint32_t            act
```

```
105     )
106     {
107         return (ActGetDataPointer(act) != NULL);
108     }
```

C.16.2.4. _plat__ACT_GetRemaining()

This function returns the remaining time. If an update is pending, *newValue* is returned. Otherwise, the current counter value is returned. Note that since the timers keep running, the returned value can get stale immediately. The actual count value will be no greater than the returned value.

```
109     LIB_EXPORT uint32_t
110     _plat__ACT_GetRemaining(
111         uint32_t             act              //IN: the ACT selector
112     )
113     {
114         P_ACT_DATA               actData = ActGetDataPointer(act);
115         uint32_t                 remain;
116     //
117         if(actData == NULL)
118             return 0;
119         remain = actData->remaining;
120         if(actData->pending)
121             remain = actData->newValue;
122         return remain;
123     }
```

C.16.2.5. _plat__ACT_GetSignaled()

```
124     LIB_EXPORT int
125     _plat__ACT_GetSignaled(
126         uint32_t             act         //IN: number of ACT to check
127     )
128     {
129         P_ACT_DATA               actData = ActGetDataPointer(act);
130     //
131         if(actData == NULL)
132             return 0;
133         return (int )actData->signaled;
134     }
```

C.16.2.6. _plat__ACT_SetSignaled()

```
135     LIB_EXPORT void
136     _plat__ACT_SetSignaled(
137         uint32_t             act,
138         int                  on
139     )
140     {
141         ActSignal(ActGetDataPointer(act), on);
142     }
```

C.16.2.7. _plat__ACT_GetPending()

```
143     LIB_EXPORT int
144     _plat__ACT_GetPending(
145         uint32_t             act         //IN: number of ACT to check
146     )
147     {
148         P_ACT_DATA               actData = ActGetDataPointer(act);
```

 Copyright © TCG 2006-2020

```
149 //
150     if(actData == NULL)
151         return 0;
152     return (int )actData->pending;
153 }
```

C.16.2.8. _plat__ACT_UpdateCounter()

This function is used to write the *newValue* for the counter. If an update is pending, then no update occurs and the function returns FALSE. If *setSignaled* is TRUE, then the ACT signaled state is SET and if *newValue* is 0, nothing is posted.

```
154 LIB_EXPORT int
155 _plat__ACT_UpdateCounter(
156     uint32_t            act,        // IN: ACT to update
157     uint32_t            newValue   // IN: the value to post
158 )
159 {
160     P_ACT_DATA          actData = ActGetDataPointer(act);
161  //
162     if(actData == NULL)
163         // actData doesn't exist but pretend update is pending rather than indicate
164         // that a retry is necessary.
165         return TRUE;
166     // if an update is pending then return FALSE so that there will be a retry
167     if(actData->pending != 0)
168         return FALSE;
169     actData->newValue = newValue;
170     actData->pending = TRUE;
171
172     return TRUE;
173 }
```

C.16.2.9. _plat__ACT_EnableTicks()

This enables and disables the processing of the once-per-second ticks. This should be turned off (*enable* = FALSE) by _TPM_Init() and turned on (*enable* = TRUE) by TPM2_Startup() after all the initializations have completed.

```
174 LIB_EXPORT void
175 _plat__ACT_EnableTicks(
176     int             enable
177 )
178 {
179     actTicksAllowed = enable;
180 }
```

C.16.2.10. ActDecrement()

If *newValue* is non-zero it is copied to *remaining* and then *newValue* is set to zero. Then *remaining* is decremented by one if it is not already zero. If the value is decremented to zero, then the associated event is signaled. If setting *remaining* causes it to be greater than 1, then the signal associated with the ACT is turned off.

```
181 static void
182 ActDecrement(
183     P_ACT_DATA              actData
184 )
185 {
186     // Check to see if there is an update pending
```

```
187         if(actData->pending)
188         {
189             // If this update will cause the count to go from non-zero to zero, set
190             // the newValue to 1 so that it will timeout when decremented below.
191             if((actData->newValue == 0) && (actData->remaining != 0))
192                 actData->newValue = 1;
193             actData->remaining = actData->newValue;
194
195             // Update processed
196             actData->pending = 0;
197         }
198         // no update so countdown if the count is non-zero but not max
199         if((actData->remaining != 0) && (actData->remaining != UINT32_MAX))
200         {
201             // If this countdown causes the count to go to zero, then turn the signal for
202             // the ACT on.
203             if((actData->remaining -= 1) == 0)
204                 ActSignal(actData, TRUE);
205         }
206         // If the current value of the counter is non-zero, then the signal should be
207         // off.
208         if(actData->signaled && (actData->remaining > 0))
209                 ActSignal(actData, FALSE);
210     }
```

C.16.2.11._plat__ACT_Tick()

This processes the once-per-second clock tick from the hardware. This is set up for the simulator to use the control interface to send ticks to the TPM. These ticks do not have to be on a per second basis. They can be as slow or as fast as desired so that the simulation can be tested.

```
211     LIB_EXPORT void
212     _plat__ACT_Tick(
213         void
214     )
215     {
216         // Ticks processing is turned off at certain times just to make sure that nothing
217         // strange is happening before pointers and things are
218         if(actTicksAllowed)
219         {
220             // Handle the update for each counter.
221     #define DECREMENT_COUNT(N)    ActDecrement(&ACT_##N);
222
223             FOR_EACH_ACT(DECREMENT_COUNT)
224         }
225     }
```

C.16.2.12.ActZero()

This function initializes a single ACT

```
226     static void
227     ActZero(
228         uint32_t        act,
229         P_ACT_DATA      actData
230     )
231     {
232         actData->remaining = 0;
233         actData->newValue = 0;
234         actData->pending = 0;
235         actData->number = (uint8_t)act;
236         ActSignal(actData, FALSE);
```

```
237 }
```

C.16.2.13._plat__ACT_Initialize()

This function initializes the ACT hardware and data structures

```
238 LIB_EXPORT int
239 _plat__ACT_Initialize(
240     void
241 )
242 {
243     actTicksAllowed = 0;
244 #define ZERO_ACT(N)  ActZero(0x##N, &ACT_##N);
245     FOR_EACH_ACT(ZERO_ACT)
246
247     return TRUE;
248 }
```

C.17 PlatformClock.h

This file contains the instance data for the Platform module. It is collected in this file so that the state of the module is easier to manage.

```
1   #ifndef _PLATFORM_CLOCK_H_
2   #define _PLATFORM_CLOCK_H_
3   #ifdef _MSC_VER
4   #include <sys/types.h>
5   #include <sys/timeb.h>
6   #else
7   #include <sys/time.h>
8   #include <time.h>
9   #endif
```

CLOCK_NOMINAL is the number of hardware ticks per *mS*. A value of 300000 means that the nominal clock rate used to drive the hardware clock is 30 MHz. The adjustment rates are used to determine the conversion of the hardware ticks to internal hardware clock value. In practice, we would expect that there woudl be a hardware register will accumulated *mS*. It would be incremented by the output of a pre-scaler. The pre-scaler would divide the ticks from the clock by some value that would compensate for the difference between clock time and real time. The code in Clock does the emulation of this function.

```
10  #define     CLOCK_NOMINAL           30000
```

A 1% change in rate is 300 counts

```
11  #define     CLOCK_ADJUST_COARSE     300
```

A 0.1% change in rate is 30 counts

```
12  #define     CLOCK_ADJUST_MEDIUM     30
```

A minimum change in rate is 1 count

```
13  #define     CLOCK_ADJUST_FINE       1
```

The clock tolerance is +/-15% (4500 counts) Allow some guard band (16.7%)

```
14  #define     CLOCK_ADJUST_LIMIT      5000
15  #endif // _PLATFORM_CLOCK_H_
```

Annex D
(informative)
Remote Procedure Interface

D.1 Introduction

These files provide an RPC interface for a TPM simulation.

The simulation uses two ports: a command port and a hardware simulation port. Only TPM commands defined in TPM 2.0 Part 3 are sent to the TPM on the command port. The hardware simulation port is used to simulate hardware events such as power on/off and locality; and indications such as _TPM_HashStart.

D.2 TpmTcpProtocol.h

D.2.1. Introduction

TPM commands are communicated as BYTE streams on a TCP connection. The TPM command protocol is enveloped with the interface protocol described in this file. The command is indicated by a UINT32 with one of the values below. Most commands take no parameters return no TPM errors. In these cases the TPM interface protocol acknowledges that command processing is completed by returning a UINT32=0. The command TPM_SIGNAL_HASH_DATA takes a UINT32-prepended variable length BYTE array and the interface protocol acknowledges command completion with a UINT32=0. Most TPM commands are enveloped using the TPM_SEND_COMMAND interface command. The parameters are as indicated below. The interface layer also appends a UIN32=0 to the TPM response for regularity.

D.2.2. Typedefs and Defines

```
1   #ifndef      TCP_TPM_PROTOCOL_H
2   #define      TCP_TPM_PROTOCOL_H
```

D.2.3. TPM Commands

All commands acknowledge processing by returning a UINT32 == 0 except where noted

```
3   #define TPM_SIGNAL_POWER_ON         1
4   #define TPM_SIGNAL_POWER_OFF        2
5   #define TPM_SIGNAL_PHYS_PRES_ON     3
6   #define TPM_SIGNAL_PHYS_PRES_OFF    4
7   #define TPM_SIGNAL_HASH_START       5
8   #define TPM_SIGNAL_HASH_DATA        6
9           // {UINT32 BufferSize, BYTE[BufferSize] Buffer}
10  #define TPM_SIGNAL_HASH_END         7
11  #define TPM_SEND_COMMAND            8
12          // {BYTE Locality, UINT32 InBufferSize, BYTE[InBufferSize] InBuffer} ->
13          //     {UINT32 OutBufferSize, BYTE[OutBufferSize] OutBuffer}
14  #define TPM_SIGNAL_CANCEL_ON        9
15  #define TPM_SIGNAL_CANCEL_OFF       10
16  #define TPM_SIGNAL_NV_ON            11
17  #define TPM_SIGNAL_NV_OFF           12

241
242         return 0;
243     }
```

D.3.2.3. PlatformSignalService()

This function starts a new thread waiting for platform signals. Platform signals are processed one at a time in the order in which they are received.

```
244     int
245     PlatformSignalService(
246         int                 PortNumber
247         )
248     {
249     #if defined(_MSC_VER)
250         HANDLE                  hPlatformSvc;
251         int                     ThreadId;
252         int                     port = PortNumber;
253     //
254         // Create service thread for platform signals
255         hPlatformSvc = CreateThread(NULL, 0,
256                                     (LPTHREAD_START_ROUTINE)PlatformSvcRoutine,
257                                     (LPVOID)(INT_PTR)port, 0, (LPDWORD)&ThreadId);
258         if(hPlatformSvc == NULL)
259         {
260             printf("Thread Creation failed\n");
261             return -1;
262         }
263         return 0;
264     #else
265         pthread_t               thread_id;
266         int                     ret;
267         int                     port = PortNumber;
268
269         ret = pthread_create(&thread_id, NULL, (void*)PlatformSvcRoutine,
270                              (LPVOID)(INT_PTR)port);
271         if (ret == -1)
272         {
273             printf("pthread_create failed: %s", strerror(ret));
274         }
275         return ret;
276     #endif // _MSC_VER
277     }
```

D.3.2.4. RegularCommandService()

This function services regular commands.

```
278     int
279     RegularCommandService(
280         int                 PortNumber
281         )
282     {
283         SOCKET                  listenSocket;
284         SOCKET                  serverSocket;
285         struct                  sockaddr_in HerAddress;
286         int                     res;
287         socklen_t               length;
```

 Copyright © TCG 2006-2020

```
288     BOOL                    continueServing;
289 //
290     res = CreateSocket(PortNumber, &listenSocket);
291     if(res != 0)
292     {
293         printf("Create platform service socket fail\n");
294         return res;
295     }
296     // Loop accepting connections one-by-one until we are killed or asked to stop
297     // Note the TPM command service is single-threaded so we don't listen for
298     // a new connection until the prior connection drops.
299     do
300     {
301         printf("TPM command server listening on port %d\n", PortNumber);
302
303         // blocking accept
304         length = sizeof(HerAddress);
305         serverSocket = accept(listenSocket,
306                               (struct sockaddr*) &HerAddress,
307                               &length);
308         if(serverSocket == INVALID_SOCKET)
309         {
310             printf("Accept error.  Error is 0x%x\n", WSAGetLastError());
311             return -1;
312         }
313         printf("Client accepted\n");
314
315         // normal behavior on client disconnection is to wait for a new client
316         // to connect
317         continueServing = TpmServer(serverSocket);
318         closesocket(serverSocket);
319     } while(continueServing);
320     return 0;
321 }
322 #if RH_ACT_0
```

D.3.2.5. SimulatorTimeServiceRoutine()

This function is called to service the time *ticks*.

```
323 static DWORD WINAPI
324 SimulatorTimeServiceRoutine(
325     LPVOID          notUsed
326 )
327 {
328     // All time is in ms
329     const INT64   tick = 1000;
330     UINT64  prevTime = _plat__RealTime();
331     INT64   timeout = tick;
332
333     (void)notUsed;
334
335     while (TRUE)

349             // or no ticks at all, it Sleep() was interrupted prematurely.
350             while (prevTime < curTime - tick / 2)
351             {
352                 //printf("%05lld | %05lld\n",
353                 //       prevTime % 100000, (curTime - tick / 2) % 100000);
354                 _plat__ACT_Tick();
355                 prevTime += (UINT64)tick;
356             }
357             // Adjust the next timeout to keep the average interval of one second
358             timeout = tick + (prevTime - curTime);
359             //prevTime = curTime;
360             //printf("%04lld | c:%05lld | p:%05llu\n",
361             //          timeout, curTime % 100000, prevTime);
362         }
363         return 0;
364     }
```

D.3.2.6. ActTimeService()

This function starts a new thread waiting to wait for time ticks.

Return Value	Meaning
==0	success
!=0	failure

```
365     static int
366     ActTimeService(
367         void
368     )
369     {
370         static BOOL          running = FALSE;
371         int                  ret = 0;
372         if(!running)
373         {
374     #if defined(_MSC_VER)
375             HANDLE               hThr;
376             int                  ThreadId;
377         //
378             printf("Starting ACT thread...\n");
379             //  Don't allow ticks to be processed before TPM is manufactured.
380             _plat__ACT_EnableTicks(FALSE);
381
382             // Create service thread for ACT internal timer
383             hThr = CreateThread(NULL, 0,
384                 (LPTHREAD_START_ROUTINE)SimulatorTimeServiceRoutine,
385                                 (LPVOID)(INT_PTR)NULL, 0, (LPDWORD)&ThreadId);
386             if(hThr != NULL)
387                 CloseHandle(hThr);
388             else
389                 ret = -1;
390     #else
391             pthread_t            thread_id;
392     //
393             ret = pthread_create(&thread_id, NULL, (void*)PlatformSvcRoutine,
394                 (LPVOID)(INT_PTR)NULL);
395     #endif // _MSC_VER
396
397             if(ret != 0)
398                 printf("ACT thread Creation failed\n");
399             else
```

```
400                 running = TRUE;
401         }
402         return ret;
403     }
404     #endif // RH_ACT_0
```

D.3.2.7. StartTcpServer()

This is the main entry-point to the TCP server. The server listens on port specified.

Note that there is no way to specify the network interface in this implementation.

```
405     int
406     StartTcpServer(
407         int                 PortNumber
408         )
409     {
410         int                     res;
411     //
412     #if RH_ACT_0 || 1
413         // Start the Time Service routine
414         res = ActTimeService();
415         if(res != 0)
416         {
417             printf("TimeService failed\n");
418             return res;
419         }
420     #endif
421
422         // Start Platform Signal Processing Service
423         res = PlatformSignalService(PortNumber + 1);
424         if(res != 0)
425         {
426             printf("PlatformSignalService failed\n");
427             return res;
428         }
429         // Start Regular/DRTM TPM command service
430         res = RegularCommandService(PortNumber);
431         if(res != 0)
432         {
433             printf("RegularCommandService failed\n");
434             return res;
435         }
436         return 0;
437     }
```

D.3.2.8. ReadBytes()

This function reads the indicated number of bytes (*NumBytes*) into buffer from the indicated socket.

```
438     BOOL
439     ReadBytes(
440         SOCKET           s,
441         char            *buffer,
442         int              NumBytes
443         )
444     {
445         int                     res;
446         int                     numGot = 0;
447     //
448         while(numGot < NumBytes)
449         {
450             res = recv(s, buffer + numGot, NumBytes - numGot, 0);
```

```
451         if(res == -1)
452         {
453             printf("Receive error.  Error is 0x%x\n", WSAGetLastError());
454             return FALSE;
455         }
456         if(res == 0)
457         {
458             return FALSE;
459         }
460         numGot += res;
461     }
462     return TRUE;
463 }
```

D.3.2.9. WriteBytes()

This function will send the indicated number of bytes (*NumBytes*) to the indicated socket

```
464 BOOL
465 WriteBytes(
466     SOCKET           s,
467     char            *buffer,
468     int              NumBytes
469     )
470 {
471     int                 res;
472     int                 numSent = 0;
473 //
474     while(numSent < NumBytes)
475     {
476         res = send(s, buffer + numSent, NumBytes - numSent, 0);
477         if(res == -1)
478         {
479             if(WSAGetLastError() == 0x2745)
480             {
481                 printf("Client disconnected\n");
482             }
483             else
484             {
485                 printf("Send error.  Error is 0x%x\n", WSAGetLastError());
486             }
487             return FALSE;
488         }
489         numSent += res;
490     }
491     return TRUE;
492 }
```

D.3.2.10. WriteUINT32()

Send 4 byte integer

```
493 BOOL
494 WriteUINT32(
495     SOCKET           s,
496     uint32_t         val
497     )
498 {
499     UINT32 netVal = htonl(val);
500 //
501     return WriteBytes(s, (char*)&netVal, 4);
502 }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

D.3.2.11. ReadUINT32()

Function to read 4 byte integer from socket.

```
503  BOOL
504  ReadUINT32(
505      SOCKET           s,
506      UINT32          *val
507  )
508  {
509      UINT32 netVal;
510  //
511      if (!ReadBytes(s, (char*)&netVal, 4))
512          return FALSE;
513      *val = ntohl(netVal);
514      return TRUE;
515  }
```

D.3.2.12. ReadVarBytes()

Get a UINT32-length-prepended binary array. Note that the 4-byte length is in network byte order (big-endian).

```
516  BOOL
517  ReadVarBytes(
518      SOCKET           s,
519      char            *buffer,
520      uint32_t        *BytesReceived,
521      int              MaxLen
522      )
523  {
524      int                     length;
525      BOOL                    res;
526  //
527      res = ReadBytes(s, (char*)&length, 4);
528      if(!res) return res;
529      length = ntohl(length);
530      *BytesReceived = length;
531      if(length > MaxLen)
532      {
533          printf("Buffer too big.  Client says %d\n", length);
534          return FALSE;
535      }
536      if(length == 0) return TRUE;
537      res = ReadBytes(s, buffer, length);
538      if(!res) return res;
539      return TRUE;
540  }
```

D.3.2.13. WriteVarBytes()

Send a UINT32-length-prepended binary array. Note that the 4-byte length is in network byte order (big-endian).

```
541  BOOL
542  WriteVarBytes(
543      SOCKET           s,
544      char            *buffer,
545      int              BytesToSend
546      )
547  {
548      uint32_t                netLength = htonl(BytesToSend);
```

```
549     BOOL res;
550 //
551     res = WriteBytes(s, (char*)&netLength, 4);
552     if(!res)
553         return res;
554     res = WriteBytes(s, buffer, BytesToSend);
555     if(!res)
556         return res;
557     return TRUE;
558 }
```

D.3.2.14. TpmServer()

Processing incoming TPM command requests using the protocol / interface defined above.

```
559 BOOL
560 TpmServer(
561     SOCKET           s
562     )
563 {
564     uint32_t              length;

D.4 TPMCmdp.c

D.4.1. Description

This file contains the functions that process the commands received on the control port or the command port of the simulator. The control port is used to allow simulation of hardware events (such as, _TPM_Hash_Start()) to test the simulated TPM's reaction to those events. This improves code coverage of the testing.

33 //** Functions
34
35 //*** Signal_PowerOn()
36 // This function processes a power-on indication. Among other things, it
37 // calls the _TPM_Init() handler.
38 void
39 _rpc__Signal_PowerOn(
40     BOOL        isReset
41     )
42 {
43     // if power is on and this is not a call to do TPM reset then return
44     if(s_isPowerOn && !isReset)
45         return;
46     // If this is a reset but power is not on, then return
47     if(isReset && !s_isPowerOn)
48         return;
49     // Unless this is just a reset, pass power on signal to platform
50     if(!isReset)
51         _plat__Signal_PowerOn();
```

 Copyright © TCG 2006-2020

```
52      // Power on and reset both lead to _TPM_Init()
53      _plat__Signal_Reset();
54
55      // Set state as power on
56      s_isPowerOn = TRUE;
57  }
```

D.4.2.1. Signal_Restart()

This function processes the clock restart indication. All it does is call the platform function.

```
58  void
59  _rpc__Signal_Restart(
60      void
61      )
62  {
63      _plat__TimerRestart();
64  }
```

D.4.2.2. Signal_PowerOff()

This function processes the power off indication. Its primary function is to set a flag indicating that the next power on indication should cause _TPM_Init() to be called.

```
65  void
66  _rpc__Signal_PowerOff(
67      void
68      )
69  {
70      if(s_isPowerOn)
71          // Pass power off signal to platform
72          _plat__Signal_PowerOff();
73      // This could be redundant, but...
74      s_isPowerOn = FALSE;
75
76      return;
77  }
```

D.4.2.3. _rpc__ForceFailureMode()

This function is used to debug the Failure Mode logic of the TPM. It will set a flag in the TPM code such that the next call to TPM2_SelfTest() will result in a failure, putting the TPM into Failure Mode.

```
78  void
79  _rpc__ForceFailureMode(
80      void
81      )
82  {
83      SetForceFailureMode();
84      return;
85  }
```

D.4.2.4. _rpc__Signal_PhysicalPresenceOn()

This function is called to simulate activation of the physical presence **pin**.

```
86  void
87  _rpc__Signal_PhysicalPresenceOn(
88      void
```

```
89      )
90  {
91      // If TPM power is on
92      if(s_isPowerOn)
93          // Pass physical presence on to platform
94          _plat__Signal_PhysicalPresenceOn();
95      return;
96  }
```

D.4.2.5. _rpc__Signal_PhysicalPresenceOff()

This function is called to simulate deactivation of the physical presence **pin**.

```
97  void
98  _rpc__Signal_PhysicalPresenceOff(
99      void
100     )
101 {
102     // If TPM is power on
103     if(s_isPowerOn)
104         // Pass physical presence off to platform
105         _plat__Signal_PhysicalPresenceOff();
106     return;
107 }
```

D.4.2.6. _rpc__Signal_Hash_Start()

This function is called to simulate a _TPM_Hash_Start() event. It will call

```
108 void
109 _rpc__Signal_Hash_Start(
110     void
111     )
112 {
113     // If TPM power is on
114     if(s_isPowerOn)
115         // Pass _TPM_Hash_Start signal to TPM
116         _TPM_Hash_Start();
117     return;
118 }
```

D.4.2.7. _rpc__Signal_Hash_Data()

This function is called to simulate a _TPM_Hash_Data() event.

```
119 void
120 _rpc__Signal_Hash_Data(
121     _IN_BUFFER       input
122     )
123 {
124     // If TPM power is on
125     if(s_isPowerOn)
126         // Pass _TPM_Hash_Data signal to TPM
127         _TPM_Hash_Data(input.BufferSize, input.Buffer);
128     return;
129 }
```

D.4.2.8. _rpc__Signal_HashEnd()

This function is called to simulate a _TPM_Hash_End() event.

```
130 void
131 _rpc__Signal_HashEnd(
132     void
133     )
134 {
135     // If TPM power is on
136     if(s_isPowerOn)
137         // Pass _TPM_HashEnd signal to TPM
138         _TPM_Hash_End();
139     return;
140 }
```

D.4.2.9. _rpc__Send_Command()

This is the interface to the TPM code.

```
141 void
142 _rpc__Send_Command(
143     unsigned char    locality,
144     _IN_BUFFER       request,
145     _OUT_BUFFER     *response
146     )
147 {
148     // If TPM is power off, reject any commands.
149     if(!s_isPowerOn)
150     {
151         response->BufferSize = 0;
152         return;
153     }
154     // Set the locality of the command so that it doesn't change during the command
155     _plat__LocalitySet(locality);
156     // Do implementation-specific command dispatch
157     _plat__RunCommand(request.BufferSize, request.Buffer,
158                       &response->BufferSize, &response->Buffer);
159     return;
160 }
```

D.4.2.10. _rpc__Signal_CancelOn()

This function is used to turn on the indication to cancel a command in process. An executing command is not interrupted. The command code may periodically check this indication to see if it should abort the current command processing and returned TPM_RC_CANCELLED.

```
161 void
162 _rpc__Signal_CancelOn(
163     void
164     )
165 {
166     // If TPM power is on
167     if(s_isPowerOn)
168         // Set the platform canceling flag.
169         _plat__SetCancel();
170     return;
171 }
```

D.4.2.11. _rpc__Signal_CancelOff()

This function is used to turn off the indication to cancel a command in process.

```
172 void
173 _rpc__Signal_CancelOff(
```

 Copyright © TCG 2006-2020

```
174         void
175         )
176     {
177         // If TPM power is on
178         if(s_isPowerOn)
179             // Set the platform canceling flag.
180             _plat__ClearCancel();
181         return;
182     }
```

D.4.2.12. _rpc__Signal_NvOn()

In a system where the NV memory used by the TPM is not within the TPM, the NV may not always be available. This function turns on the indicator that indicates that NV is available.

```
183     void
184     _rpc__Signal_NvOn(
185         void
186         )
187     {
188         // If TPM power is on
189         if(s_isPowerOn)
190             // Make the NV available
191             _plat__SetNvAvail();
192         return;
193     }
```

D.4.2.13. _rpc__Signal_NvOff()

This function is used to set the indication that NV memory is no longer available.

```
194     void
195     _rpc__Signal_NvOff(
196         void
197         )
198     {
199         // If TPM power is on
200         if(s_isPowerOn)
201             // Make NV not available
202             _plat__ClearNvAvail();
203         return;
204     }
205     void RsaKeyCacheControl(int state);
```

D.4.2.14. _rpc__RsaKeyCacheControl()

This function is used to enable/disable the use of the RSA key cache during simulation.

```
206     void
207     _rpc__RsaKeyCacheControl(
208         int              state
209         )
210     {
211     #if USE_RSA_KEY_CACHE
212         RsaKeyCacheControl(state);
213     #else
214         NOT_REFERENCED(state);
215     #endif
216         return;
217     }
218     #define TPM_RH_ACT_0        0x40000110
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

D.4.2.15. _rpc__ACT_GetSignaled()

This function is used to count the ACT second tick.

```
219 BOOL
220 _rpc__ACT_GetSignaled(
221     UINT32 actHandle
222 )
223 {
224     // If TPM power is on
225     if (s_isPowerOn)
226         // Query the platform
227         return _plat__ACT_GetSignaled(actHandle - TPM_RH_ACT_0);
228     return FALSE;
229 }
```

D.5 TPMCmds.c

D.5.1. Description

This file contains the entry point for the simulator.

D.5.2. Includes, Defines, Data Definitions, and Function Prototypes

```

Information about command line arguments (does not include program name)

```
32  static uint32_t     s_ArgsMask = 0;     // Bit mask of unmatched command line args
33  static int          s_Argc = 0;
34  static const char **s_Argv = NULL;
35
36  //** Functions
37
38  #if DEBUG
39  //*** Assert()
40  // This function implements a run-time assertion.
41  // Computation of its parameters must not result in any side effects, as these
42  // computations will be stripped from the release builds.
43  static void Assert (BOOL cond, const char* msg)
44  {
45      if (cond)
46          return;
47      fputs(msg, stderr);
48      exit(2);
49  }
50  #else
51  #define Assert(cond, msg)
```

```
52  #endif
```

D.5.2.1. Usage()

This function prints the proper calling sequence for the simulator.

```
53  static void
54  Usage(
55      const char          *programName
56  )
57  {
58      fprintf(stderr, "%s\n\n", PURPOSE);
59      fprintf(stderr, "Usage:  %s [PortNum] [opts]\n\n"
60          "Starts the TPM server listening on TCP port PortNum (by default %d).\n\n"
61          "An option can be in the short form (one letter preceded with '-' or '/')\n"
62          "or in the full form (preceded with '--' or no option marker at all).\n"
63          "Possible options are:\n"
64          "   -h (--help) or ? - print this message\n"
65          "   -m (--manufacture) - forces NV state of the TPM simulator to be "
66          "(re)manufactured\n",
67          programName, DEFAULT_TPM_PORT);
68      exit(1);
69  }
```

D.5.2.2. CmdLineParser_Init()

This function initializes command line option parser.

```
70  static BOOL
71  CmdLineParser_Init(
72      int argc,
73      char *argv[],
74      int maxOpts
75      )
76  {
77      if (argc == 1)
78          return FALSE;
79
80      if (maxOpts && (argc - 1) > maxOpts)
81      {
82          fprintf(stderr, "No more than %d options can be specified\n\n", maxOpts);
83          Usage(argv[0]);
84      }
85
86      s_Argc = argc - 1;
87      s_Argv = (const char**)(argv + 1);
88      s_ArgsMask = (1 << s_Argc) - 1;
89      return TRUE;
90  }
```

D.5.2.3. CmdLineParser_More()

Returns true if there are unparsed options still.

```
91  static BOOL
92  CmdLineParser_More(
93      void
94  )
95  {
96      return s_ArgsMask != 0;
97  }
```

D.5.2.4. CmdLineParser_IsOpt()

This function determines if the given command line parameter represents a valid option.

```
98   static BOOL
99   CmdLineParser_IsOpt(
100      const char* opt,         // Command line parameter to check
101      const char* optFull,     // Expected full name
102      const char* optShort,    // Expected short (single letter) name
103      BOOL dashed              // The parameter is preceded by a single dash
104      )
105  {
106      return 0 == strcmp(opt, optFull)
107          || (optShort && opt[0] == optShort[0] && opt[1] == 0)
108          || (dashed && opt[0] == '-' && 0 == strcmp(opt + 1, optFull));
109  }
```

D.5.2.5. CmdLineParser_IsOptPresent()

This function determines if the given command line parameter represents a valid option.

```
110  static BOOL
111  CmdLineParser_IsOptPresent(
112      const char* optFull,
113      const char* optShort
114      )
115  {
116      int          i;
117      int          curArgBit;
118      Assert(s_Argv != NULL,
119          "InitCmdLineOptParser(argc, argv) has not been invoked\n");
120      Assert(optFull && optFull[0],
121          "Full form of a command line option must be present.\n"
122          "If only a short (single letter) form is supported, it must be"
123          "specified as the full one.\n");
124      Assert(!optShort || (optShort[0] && !optShort[1]),
125          "If a short form of an option is specified, it must consist "
126          "of a single letter only.\n");
127
128      if (!CmdLineParser_More())
129          return FALSE;
130
131      for (i = 0, curArgBit = 1; i < s_Argc; ++i, curArgBit <<= 1)
132      {
133          const char* opt = s_Argv[i];
134          if (    (s_ArgsMask & curArgBit) && opt
135              && (    0 == strcmp(opt, optFull)
136                  || (    (opt[0] == '/' || opt[0] == '-')
137                      && CmdLineParser_IsOpt(opt + 1, optFull, optShort,
138                                             opt[0] == '-'))))
139          {
140              s_ArgsMask ^= curArgBit;
141              return TRUE;
142          }
143      }
144      return FALSE;
145  }
```

D.5.2.6. CmdLineParser_IsOptPresent()

This function notifies the parser that no more options are needed.

```
146  static void
147  CmdLineParser_Done(
148      const char          *programName
149  )
150  {
151      char delim = ':';
152      int         i;
153      int         curArgBit;
154
155      if (!CmdLineParser_More())
156          return;
157
158      fprintf(stderr, "Command line contains unknown option%s",
159              s_ArgsMask & (s_ArgsMask - 1) ? "s" : "");
160      for (i = 0, curArgBit = 1; i < s_Argc; ++i, curArgBit <<= 1)
161      {
162          if (s_ArgsMask & curArgBit)
163          {
164              fprintf(stderr, "%c %s", delim, s_Argv[i]);
165              delim = ',';
166          }
167      }
168      fprintf(stderr, "\n\n");
169      Usage(programName);
170  }
```

D.5.2.7. main()

This is the main entry point for the simulator. It registers the interface and starts listening for clients

```
171  int
172  main(
173      int              argc,
174      char            *argv[]
175      )
176  {
177      BOOL    manufacture = FALSE;
178      int     PortNum = DEFAULT_TPM_PORT;
179
180      // Parse command line options
181
182      if (CmdLineParser_Init(argc, argv, 2))
183      {
184          if (   CmdLineParser_IsOptPresent("?", "?")
185              || CmdLineParser_IsOptPresent("help", "h"))
186          {
187              Usage(argv[0]);
188          }
189          if (CmdLineParser_IsOptPresent("manufacture", "m"))
190          {
191              manufacture = TRUE;
192          }
193          if (CmdLineParser_More())
194          {
195              int     i;
196              for (i = 0; i < s_Argc; ++i)
197              {
198                  char *nptr = NULL;
199                  int portNum = (int)strtol(s_Argv[i], &nptr, 0);
200                  if (s_Argv[i] != nptr)
201                  {
202                      // A numeric option is found
203                      if(!*nptr && portNum > 0 && portNum < 65535)
204                      {
```

```
205                         PortNum = portNum;
206                         s_ArgsMask ^= 1 << i;
207                         break;
208                     }
209                     fprintf(stderr, "Invalid numeric option %s\n\n", s_Argv[i]);
210                     Usage(argv[0]);
211                 }
212             }
213         }
214         CmdLineParser_Done(argv[0]);
215     }
216     printf("LIBRARY_COMPATIBILITY_CHECK is %s\n",
217          (LIBRARY_COMPATIBILITY_CHECK ? "ON" : "OFF"));
218     // Enable NV memory
219     _plat__NVEnable(NULL);
220
221     if (manufacture || _plat__NVNeedsManufacture())
222     {
223         printf("Manufacturing NV state...\n");
224         if(TPM_Manufacture(1) != 0)
225         {
226             // if the manufacture didn't work, then make sure that the NV file doesn't
227             // survive. This prevents manufacturing failures from being ignored the
228             // next time the code is run.
229             _plat__NVDisable(1);
230             exit(1);
231         }
232         // Coverage test - repeated manufacturing attempt
233         if(TPM_Manufacture(0) != 1)
234         {
235             exit(2);
236         }
237         // Coverage test - re-manufacturing
238         TPM_TearDown();
239         if(TPM_Manufacture(1) != 0)
240         {
241             exit(3);
242         }
243     }
244     // Disable NV memory
245     _plat__NVDisable(0);
246
247     StartTcpServer(PortNum);
248     return EXIT_SUCCESS;
249 }

Trusted Platform Module Library
Part 4: Supporting Routines

1 Scope

This part contains C code that describes the algorithms and methods used by the command code in TPM 2.0 Part 3. The code in this document augments TPM 2.0 Part 2 and TPM 2.0 Part 3 to provide a complete description of a TPM, including the supporting framework for the code that performs the command actions.

Any TPM 2.0 Part 4 code may be replaced by code that provides similar results when interfacing to the action code in TPM 2.0 Part 3. The behavior of code in this document that is not included in an annex is *normative*, as observed at the interfaces with TPM 2.0 Part 3 code. Code in an annex is provided for completeness, that is, to allow a full implementation of the specification from the provided code.

The code in parts 3 and 4 is written to define the behavior of a compliant TPM. In some cases (e.g., firmware update), it is not possible to provide a compliant implementation. In those cases, any implementation provided by the vendor that meets the general description of the function provided in TPM 2.0 Part 3 would be compliant.

The code in parts 3 and 4 is not written to meet any particular level of conformance nor does this specification require that a TPM meet any particular level of conformance.

2 Terms and definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

4 Automation

TPM 2.0 Part 2 and 3 are constructed so that they can be processed by an automated parser. For example, TPM 2.0 Part 2 can be processed to generate header file contents such as structures, typedefs, and enums. TPM 2.0 Part 3 can be processed to generate command and response marshaling and unmarshaling code.

The automated processor is not provided by the TCG. It was used to generate the Microsoft Visual Studio TPM simulator files. These files are not specification reference code, but rather design examples.

The automation produces TPM_Types.h, a header representing TPM 2.0 Part 2. It also produces, for each major clause of Part 4, a header of the form _fp.h with the function prototypes.

EXAMPLE The header file for SessionProcess.c is SessionProcess_fp.h.

4.1 Configuration Parser

The TPM configuration is largely defined by TpmProfiles.h. This file may be edited in order to change the algorithms and commands supported by a TPM implementation.

A parser exists to process a Word document that defines the TPM configuration. This parser is used to create TpmProfiles.h.

 Copyright © TCG 2006-2020

4.2 Structure Parser

4.2.1 Introduction

The program that processes the tables in TPM 2.0 Part 2 is called "The TPM 2.0 Part 2 Structure Parser."

NOTE A Perl script was used to parse the tables in TPM 2.0 Part 2 to produce the header files and unmarshaling code in for the reference implementation.

The TPM 2.0 Part 2 Structure Parser takes as input the files produced by the TPM 2.0 Part 2 Configuration Parser and the same TPM 2.0 Part 2 specification that was used as input to the TPM 2.0 Part 2 Configuration Parser. The TPM 2.0 Part 2 Structure Parser will generate all of the C structure constant definitions that are required by the TPM interface. Additionally, the parser will generate unmarshaling code for all structures passed to the TPM, and marshaling code for structures passed from the TPM.

The unmarshaling code produced by the parser uses the prototypes defined below. The unmarshaling code will perform validations of the data to ensure that it is compliant with the limitations on the data imposed by the structure definition and use the response code provided in the table if not.

EXAMPLE: The definition for a TPMI_RH_PROVISION indicates that the primitive data type is a TPM_HANDLE and the only allowed values are TPM_RH_OWNER and TPM_RH_PLATFORM. The definition also indicates that the TPM shall indicate TPM_RC_HANDLE if the input value is not none of these values. The unmarshaling code will validate that the input value has one of those allowed values and return TPM_RC_HANDLE if not.

The sections below describe the function prototypes for the marshaling and unmarshaling code that is automatically generated by the TPM 2.0 Part 2 Structure Parser. These prototypes are described here as the unmarshaling and marshaling of various types occurs in places other than when the command is being parsed or the response is being built. The prototypes and the description of the interface are intended to aid in the comprehension of the code that uses these auto-generated routines.

4.2.2 Unmarshaling Code Prototype

4.2.2.1 Simple Types and Structures

The general form for the unmarshaling code for a simple type or a structure is:

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size);
```

Where:

TYPE	name of the data type or structure
***target**	location in the TPM memory into which the data from ****buffer** is placed
****buffer**	location in input buffer containing the most significant octet (MSO) of ***target**
***size**	number of octets remaining in ****buffer**

When the data is successfully unmarshaled, the called routine will return TPM_RC_SUCCESS. Otherwise, it will return a Format-One response code (see TPM 2.0 Part 2).

If the data is successfully unmarshaled, ***buffer** is advanced point to the first octet of the next parameter in the input buffer and **size** is reduced by the number of octets removed from the buffer.

When the data type is a simple type, the parser will generate code that will unmarshal the underlying type and then perform checks on the type as indicated by the type definition.

When the data type is a structure, the parser will generate code that unmarshals each of the structure elements in turn and performs any additional parameter checks as indicated by the data type.

4.2.2.2 Union Types

When a union is defined, an extra parameter is defined for the unmarshaling code. This parameter is the selector for the type. The unmarshaling code for the union will unmarshal the type indicated by the selector.

The function prototype for a union has the form:

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size, UINT32 selector);
```

where:

TYPE	name of the union type or structure
***target**	location in the TPM memory into which the data from ****buffer** is placed
****buffer**	location in input buffer containing the most significant octet (MSO) of ***target**
***size**	number of octets remaining in ****buffer**
selector	union selector that determines what will be unmarshaled into ***target**

4.2.2.3 Null Types

In some cases, the structure definition allows an optional "null" value. The "null" value allows the use of the same C type for the entity even though it does not always have the same members.

For example, the TPMI_ALG_HASH data type is used in many places. In some cases, TPM_ALG_NULL is permitted and in some cases it is not. If two different data types had to be defined, the interfaces and code would become more complex because of the number of cast operations that would be necessary. Rather than encumber the code, the "null" value is defined and the unmarshaling code is given a flag to indicate if this instance of the type accepts the "null" parameter or not. When the data type has a "null" value, the function prototype is

```
TPM_RC TYPE_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size, BOOL flag);
```

The parser detects when the type allows a "null" value and will always include **flag** in any call to unmarshal that type. **flag** TRUE indicates that null is accepted.

4.2.2.4 Arrays

Any data type may be included in an array. The function prototype use to unmarshal an array for a **TYPE** is

```
TPM_RC TYPE_Array_Unmarshal(TYPE *target, BYTE **buffer, INT32 *size,INT32 count);
```

The generated code for an array uses a **count**-limited loop within which it calls the unmarshaling code for **TYPE**.

4.2.3 Marshaling Code Function Prototypes

4.2.3.1 Simple Types and Structures

The general form for the marshaling code for a simple type or a structure is:

```
UINT16 TYPE_Marshal(TYPE *source, BYTE **buffer, INT32 *size);
```

Where:

TYPE	name of the data type or structure
***source**	location in the TPM memory containing the value that is to be marshaled in to the designated buffer
****buffer**	location in the output buffer where the first octet of the **TYPE** is to be placed
***size**	number of octets remaining in ****buffer**.

If **buffer** is a NULL pointer, then no data is marshaled, but the routine will compute and return the size of the memory required to marshal the indicated type. ***size** is not changed.

If **buffer** is not a NULL pointer, data is marshaled, ***buffer** is advanced to point to the first octet of the next location in the output buffer, and the called routine will return the number of octets marshaled into ****buffer**. This occurs even if **size** is a NULL pointer. If **size** is a not NULL pointer ***size** is reduced by the number of octets placed in the buffer.

When the data type is a simple type, the parser will generate code that will marshal the underlying type. The presumption is that the TPM internal structures are consistent and correct so the marshaling code does not validate that the data placed in the buffer has a permissible value. The presumption is also that the **size** is sufficient for the source being marshaled.

When the data type is a structure, the parser will generate code that marshals each of the structure elements in turn.

4.2.3.2 Union Types

An extra parameter is defined for the marshaling function of a union. This parameter is the selector for the type. The marshaling code for the union will marshal the type indicated by the selector.

The function prototype for a union has the form:

```
UINT16 TYPE_Marshal(TYPE *source, BYTE **buffer, INT32 *size, UINT32 selector);
```

The parameters have a similar meaning as those in 4.2.2.2 but the data movement is from **source** to **buffer**.

4.2.3.3 Arrays

Any type may be included in an array. The function prototype use to unmarshal an array is:

```
UINT16 TYPE_Array_Marshal(TYPE *source, BYTE **buffer, INT32 *size, INT32 count);
```

4.2.3.4 The generated code for an array uses a count-limited loop within which it calls the marshaling code for TYPE.Table-driven Marshaling

The most recent versions of the TPM code includes the option to use table-driven marshaling rather that the procedural marshaling described in previous clauses in 4.2.2. The structure and processing of this code is complex and is provided in the code.

 Copyright © TCG 2006-2020

4.3 Part 3 Parsing

The Command / Response tables in Part 3 of this specification are processed by scripts to produce the command-specific data structures used by functions in this TPM 2.0 Part 4. They are:

- **CommandAttributeData.h** -- This file contains the command attributes reported by TPM2_GetCapability.
- **CommandAttributes.h** – This file contains the definition of command attributes that are extracted by the parsing code. The file mainly exists to ensure that the parsing code and the function code are using the same attributes.
- **CommandDispatchData.h** – This file contains the data definitions for the table driven version of the command dispatcher.

Part 3 parsing also produces special function prototype files as described in 4.4.

4.4 Function Prototypes

For functions that have entry definitions not defined by Part 3 tables. a script is used to extracts function prototypes from the code. For each .c file that is not in Part 3, a file with the same name is created with a suffix of _fp.h. For example, the function prototypes for Create.c will be placed in a file called Create_fp.h. The _fp.h is added because some files have two types of associated headers: the one containing the function prototypes for the file and another containing definitions that are specific to that file.

In some cases, a function will be replaced by a macro. The macro is defined in the .c file and extracted by the function prototype processor. A special comment tag ("//%") is used to indicate that the line is to be included in the function prototype file. If the "//%" tag occurs at the start of the line, it is deleted. If it occurs later in the line, it is preserved. Removing the "//%/ at the start of the line allows the macro to be placed in the .c file with the tag as a prefix, and then show up in the _fp.h file as the actual macro. This allows the code that includes that function prototype code to use the appropriate macro.

For files that that contain the command actions, a special _fp.h file is created from the tables in Part 3. These files contain:

- the definition of the input and output structure of the function;
- definition of command-specific return code modifiers (parameter identifiers); and
- the function prototype for the command action function.

Create_fp.h (shown below) is prototypical of the command _fp.h files.

`[[create_fp_h]]`

4.5 Portability

Where reasonable, the code is written to be portable. There are a few known cases where the code is not portable. Specifically, the handling of bit fields will not always be portable. The bit fields are marshaled and unmarshaled as a simple element of the underlying type. For example, a TPMA_SESSION is defined as a bit field in an octet (BYTE). When sent on the interface a TPMA_SESSION will occupy one octet. When unmarshaled, it is unmarshaled as a UINT8. The ramifications of this are that a TPMA_SESSION will occupy the 0th octet of the structure in which it is placed regardless of the size of the structure.

Many compilers will pad a bit field to some "natural" size for the processor, often 4 octets, meaning that `sizeof(TPMA_SESSION)` would return 4 rather than 1 (the canonical size of a TPMA_SESSION).

For a little endian machine, padding of bit fields should have little consequence since the 0th octet always contains the 0th bit of the structure no matter how large the structure. However, for a big endian machine, the 0th bit will be in the highest numbered octet. When unmarshaling a TPMA_SESSION, the current

 Copyright © TCG 2006-2020

unmarshaling code will place the input octet at the 0th octet of the TPMA_SESSION. Since the 0th octet is most significant octet, this has the effect of shifting all the session attribute bits left by 24 places.

As a consequence, someone implementing on a big endian machine should do one of two things:

a) allocate all structures as packed to a byte boundary (this may not be possible if the processor does not handle unaligned accesses); or

b) modify the code that manipulates bit fields that are not defined as being the alignment size of the system.

For many RISC processors, option #2 would be the only choice. This is may not be a terribly daunting task since only two attribute structures are not 32-bits (TPMA_SESSION and TPMA_LOCALITY).

5 Header Files

5.1 Introduction

The files in this section are used to define values that are used in multiple parts of the specification and are not confined to a single module.

5.2 BaseTypes.h

[[BaseTypes_h]]

5.3 Capabilities.h

This file contains defines for the number of capability values that will fit into the largest data buffer.

These defines are used in various function in the "support" and the "subsystem" code groups. A module that supports a type that is returned by a capability will have a function that returns the capabilities of the type.

EXAMPLE PCR.c contains PCRCapGetHandles() and PCRCapGetProperties().

6 Main

6.1 Introduction

The files in this section are the main processing blocks for the TPM. ExecuteCommand.c contains the entry point into the TPM code and the parsing of the command header. SessionProcess.c handles the parsing of the session area and the authorization checks, and CommandDispatch.c does the parameter unmarshaling and command dispatch.

6.2 ExecCommand.c

[[ExecCommand]]

 Copyright © TCG 2006-2020

6.3 CommandDispatcher.c

6.3.1 Introduction

CommandDispatcher() performs the following operations:

- unmarshals command parameters from the input buffer;

NOTE 1 Unlike other unmarshaling functions, *parmBufferStart* does not advance. *parmBufferSize* Is reduced.

- invokes the function that performs the command actions;
- marshals the returned handles, if any; and
- marshals the returned parameters, if any, into the output buffer putting in the *parameterSize* field if authorization sessions are present.

NOTE 2 The output buffer is the return from the MemoryGetResponseBuffer() function. It includes the header, handles, response parameters, and authorization area. *respParmSize* is the response parameter size, and does not include the header, handles, or authorization area.

NOTE 3 The reference implementation is permitted to do compare operations over a union as a byte array. Therefore, the command parameter *in* structure must be initialized (e.g., zeroed) before unmarshaling so that the compare operation is valid in cases where some bytes are unused.

7 Command Support Functions

7.1 Introduction

This clause contains support routines that are called by the command action code in TPM 2.0 Part 3. The functions are grouped by the command group that is supported by the functions.

9.10 Marshal.c

9.10.1 Introduction

This file contains the marshaling and unmarshaling code.

The marshaling and unmarshaling code and function prototypes are not listed, as the code is repetitive, long, and not very useful to read. Examples of a few unmarshaling routines are provided. Most of the others are similar.

Depending on the table header flags, a type will have an unmarshaling routine and a marshaling routine The table header flags that control the generation of the unmarshaling and marshaling code are delimited by angle brackets ("<>") in the table header. If no brackets are present, then both unmarshaling and marshaling code is generated (i.e., generation of both marshaling and unmarshaling code is the default).

9.10.2 Unmarshal and Marshal a Value

In TPM 2.0 Part 2, a TPMI_DI_OBJECT is defined by this table:

Table xxx — Definition of (TPM_HANDLE) TPMI_DH_OBJECT Type

Values	Comments
{TRANSIENT_FIRST:TRANSIENT_LAST}	allowed range for transient objects
{PERSISTENT_FIRST:PERSISTENT_LAST}	allowed range for persistent objects
+TPM_RH_NULL	the null handle
#TPM_RC_VALUE	

This generates the following unmarshaling code:

```
1   TPM_RC
2   TPMI_DH_OBJECT_Unmarshal(TPMI_DH_OBJECT *target, BYTE **buffer, INT32 *size,
3                            BOOL flag)
4   {
5       TPM_RC    result;
6       result = TPM_HANDLE_Unmarshal((TPM_HANDLE *)target, buffer, size);
7       if(result != TPM_RC_SUCCESS)
8           return result;
9       if(*target == TPM_RH_NULL)
10      {
11          if(flag)
12              return TPM_RC_SUCCESS;
13          else
14              return TPM_RC_VALUE;
15      }
16      if(((*target < TRANSIENT_FIRST) || (*target > TRANSIENT_LAST))
17        &&((*target < PERSISTENT_FIRST) || (*target > PERSISTENT_LAST)))
18              return TPM_RC_VALUE;
19      return TPM_RC_SUCCESS;
20  }
```

and the following marshaling code:

NOTE The marshaling code does not do parameter checking, as the TPM is the source of the marshaling data.

```
1   UINT16
2   TPMI_DH_OBJECT_Marshal(TPMI_DH_OBJECT *source, BYTE **buffer, INT32 *size)
```

```
3    {
4        return UINT32_Marshal((UINT32 *)source, buffer, size);
5    }
```

An additional script is used to do the work that might be done by a linker or globally optimizing compiler. It searches for functions like TPMI_DH_OBJECT_Marshal() that do nothing but call another function and replaces the function with a #define.

```
6    #define TPMI_DH_OBJECT_Marshal(source, buffer, size)     \
7          UINT32_Marshal((UINT32 *)source, buffer, size)
```

When replacing the function with a #define, the #define is placed in marshal_fp.h and the function body is removed from marshal.c.

9.10.3 Unmarshal and Marshal a Union

In TPM 2.0 Part 2, a TPMU_PUBLIC_PARMS union is defined by:

Table xxx — Definition of TPMU_PUBLIC_PARMS Union <IN/OUT, S>

Parameter	Type	Selector	Description
keyedHash	TPMS_KEYEDHASH_PARMS	TPM_ALG_KEYEDHASH	sign | encrypt | neither
symDetail	TPMT_SYM_DEF_OBJECT	TPM_ALG_SYMCIPHER	a symmetric block cipher
rsaDetail	TPMS_RSA_PARMS	TPM_ALG_RSA	decrypt + sign
eccDetail	TPMS_ECC_PARMS	TPM_ALG_ECC	decrypt + sign
asymDetail	TPMS_ASYM_PARMS		common scheme structure for RSA and ECC keys
NOTE The Description column indicates which of TPMA_OBJECT.*decrypt* or TPMA_OBJECT.*sign* may be set. "+" indicates that both may be set but one shall be set. "|" indicates the optional settings.			

From this table, the following unmarshaling code is generated.

```
1    TPM_RC
2    TPMU_PUBLIC_PARMS_Unmarshal(TPMU_PUBLIC_PARMS *target, BYTE **buffer, INT32 *size,
3                                UINT32 selector)
4    {
5        switch(selector) {
6    #if ALG_KEYEDHASH
7            case TPM_ALG_KEYEDHASH:
8                return TPMS_KEYEDHASH_PARMS_Unmarshal(
9                           (TPMS_KEYEDHASH_PARMS *)&(target->keyedHash), buffer, size);
10   #endif
11   #if ALG_SYMCIPHER
12           case TPM_ALG_SYMCIPHER:
13               return TPMT_SYM_DEF_OBJECT_Unmarshal(
14                       (TPMT_SYM_DEF_OBJECT *)&(target->symDetail), buffer, size, FALSE);
15   #endif
16   #if ALG_RSA
17           case TPM_ALG_RSA:
18               return TPMS_RSA_PARMS_Unmarshal(
19                               (TPMS_RSA_PARMS *)&(target->rsaDetail), buffer, size);
20   #endif
21   #if ALG_ECC
22           case TPM_ALG_ECC:
23               return TPMS_ECC_PARMS_Unmarshal(
24                               (TPMS_ECC_PARMS *)&(target->eccDetail), buffer, size);
25   #endif
26       }
```

```
27      return TPM_RC_SELECTOR;
28  }
```

NOTE The `#if/#endif` directives are added whenever a value is dependent on an algorithm ID so that removing the algorithm definition will remove the related code.

The marshaling code for the union is:

```
1   UINT16
2   TPMU_PUBLIC_PARMS_Marshal(TPMU_PUBLIC_PARMS *source, BYTE **buffer, INT32 *size,
3                             UINT32 selector)
4   {
5       switch(selector) {
6   #if ALG_KEYEDHASH
7           case TPM_ALG_KEYEDHASH:
8               return TPMS_KEYEDHASH_PARMS_Marshal(
9                           (TPMS_KEYEDHASH_PARMS *)&(source->keyedHash), buffer, size);
10  #endif
11  #if ALG_SYMCIPHER
12          case TPM_ALG_SYMCIPHER:
13              return TPMT_SYM_DEF_OBJECT_Marshal(
14                          (TPMT_SYM_DEF_OBJECT *)&(source->symDetail), buffer, size);
15  #endif
16  #if ALG_RSA
17          case TPM_ALG_RSA:
18              return TPMS_RSA_PARMS_Marshal(
19                          (TPMS_RSA_PARMS *)&(source->rsaDetail), buffer, size);
20  #endif
21  #if ALG_ECC
22          case TPM_ALG_ECC:
23              return TPMS_ECC_PARMS_Marshal(
24                          (TPMS_ECC_PARMS *)&(source->eccDetail), buffer, size);
25  #endif
26      }
27      assert(1);
28      return 0;
29  }
```

For the marshaling and unmarshaling code, a value in the structure containing the union provides the value used for *selector*. The example in the next section illustrates this.

 Copyright © TCG 2006-2020

9.10.4 Unmarshal and Marshal a Structure

In TPM 2.0 Part 2, the TPMT_PUBLIC structure is defined by:

Table xxx — Definition of TPMT_PUBLIC Structure

Parameter	Type	Description
type	TPMI_ALG_PUBLIC	“algorithm” associated with this object
nameAlg	+TPMI_ALG_HASH	algorithm used for computing the Name of the object NOTE The "+" indicates that the instance of a TPMT_PUBLIC may have a "+" to indicate that the nameAlg may be TPM_ALG_NULL.
objectAttributes	TPMA_OBJECT	attributes that, along with *type*, determine the manipulations of this object
authPolicy	TPM2B_DIGEST	optional policy for using this key The policy is computed using the *nameAlg* of the object. NOTE shall be the Empty Buffer if no authorization policy is present
[type]parameters	TPMU_PUBLIC_PARMS	the algorithm or structure details
[type]unique	TPMU_PUBLIC_ID	the unique identifier of the structure For an asymmetric key, this would be the public key.

This structure is tagged (the first value indicates the structure type), and that tag is used to determine how the parameters and unique fields are unmarshaled and marshaled. The use of the type for specifying the union selector is emphasized below.

The unmarshaling code for the structure in the table above is:

```
1   TPM_RC
2   TPMT_PUBLIC_Unmarshal(TPMT_PUBLIC *target, BYTE **buffer, INT32 *size, BOOL flag)
3   {
4       TPM_RC     result;
5       result = TPMI_ALG_PUBLIC_Unmarshal((TPMI_ALG_PUBLIC *)&(target->type),
6                                          buffer, size);
7       if(result != TPM_RC_SUCCESS)
8           return result;
9       result = TPMI_ALG_HASH_Unmarshal((TPMI_ALG_HASH *)&(target->nameAlg),
10                                       buffer, size, flag);
11      if(result != TPM_RC_SUCCESS)
12          return result;
13      result = TPMA_OBJECT_Unmarshal((TPMA_OBJECT *)&(target->objectAttributes),
14                                     buffer, size);
15      if(result != TPM_RC_SUCCESS)
16          return result;
17      result = TPM2B_DIGEST_Unmarshal((TPM2B_DIGEST *)&(target->authPolicy),
18                                      buffer, size);
19      if(result != TPM_RC_SUCCESS)
20          return result;
21
22      result = TPMU_PUBLIC_PARMS_Unmarshal((TPMU_PUBLIC_PARMS *)&(target->parameters),
23                                           buffer, size, (UINT32)target->type);
24      if(result != TPM_RC_SUCCESS)
25          return result;
26
27      result = TPMU_PUBLIC_ID_Unmarshal((TPMU_PUBLIC_ID *)&(target->unique),
28                                        buffer, size, (UINT32)target->type);
29      if(result != TPM_RC_SUCCESS)
30          return result;
31
32      return TPM_RC_SUCCESS;
33  }
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

The marshaling code for the TPMT_PUBLIC structure is:

```
1  UINT16
2  TPMT_PUBLIC_Marshal(TPMT_PUBLIC *source, BYTE **buffer, INT32 *size)
3  {
4      UINT16    result = 0;
5      result = (UINT16)(result + TPMI_ALG_PUBLIC_Marshal(
6                                  (TPMI_ALG_PUBLIC *)&(source->type), buffer, size));
7      result = (UINT16)(result + TPMI_ALG_HASH_Marshal(
8                                  (TPMI_ALG_HASH *)&(source->nameAlg), buffer, size))
9  ;
10     result = (UINT16)(result + TPMA_OBJECT_Marshal(
11                           (TPMA_OBJECT *)&(source->objectAttributes), buffer, size));
12
13     result = (UINT16)(result + TPM2B_DIGEST_Marshal(
14                               (TPM2B_DIGEST *)&(source->authPolicy), buffer, size));
15
16     result = (UINT16)(result + TPMU_PUBLIC_PARMS_Marshal(
17                           (TPMU_PUBLIC_PARMS *)&(source->parameters), buffer, size,
18                                                            (UINT32)source->type));
19
20     result = (UINT16)(result + TPMU_PUBLIC_ID_Marshal(
21                                 (TPMU_PUBLIC_ID *)&(source->unique), buffer, size,
22                                                            (UINT32)source->type));
23
24     return result;
25 }
```

9.10.5 Unmarshal and Marshal an Array

In TPM 2.0 Part 2, the TPML_DIGEST is defined by:

Table xxx — Definition of TPML_DIGEST Structure

Parameter	Type	Description
count {2:}	UINT32	number of digests in the list, minimum is two
digests[count]{:8}	TPM2B_DIGEST	a list of digests For TPM2_PolicyOR(), all digests will have been computed using the digest of the policy session. For TPM2_PCR_Read(), each digest will be the size of the digest for the bank containing the PCR.
#TPM_RC_SIZE		response code when count is not at least two or is greater than 8

The *digests* parameter is an array of up to *count* structures (TPM2B_DIGESTS). The auto-generated code to Unmarshal this structure is:

```
1  TPM_RC
2  TPML_DIGEST_Unmarshal(TPML_DIGEST *target, BYTE **buffer, INT32 *size)
3  {
4      TPM_RC    result;
5      result = UINT32_Unmarshal((UINT32 *)&(target->count), buffer, size);
6      if(result != TPM_RC_SUCCESS)
7          return result;
8
9      if( (target->count < 2))     // This check is triggered by the {2:} notation
10                                  // on 'count'
11         return TPM_RC_SIZE;
12
13     if((target->count) > 8)      // This check is triggered by the {:8} notation
```

 Copyright © TCG 2006-2020

```
14                                   // on 'digests'.
15             return TPM_RC_SIZE;
16
17         result = TPM2B_DIGEST_Array_Unmarshal((TPM2B_DIGEST *)(target->digests),
18                                               buffer, size, (INT32)(target->count));
19         if(result != TPM_RC_SUCCESS)
20             return result;
21
22         return TPM_RC_SUCCESS;
23     }
```

The routine unmarshals a *count* value and passes that value to a routine that unmarshals an array of TPM2B_DIGEST values. The unmarshaling code for the array is:

```
1   TPM_RC
2   TPM2B_DIGEST_Array_Unmarshal(TPM2B_DIGEST *target, BYTE **buffer, INT32 *size,
3                                INT32 count)
4   {
5       TPM_RC    result;
6       INT32 i;
7       for(i = 0; i < count; i++) {
8           result = TPM2B_DIGEST_Unmarshal(&target[i], buffer, size);
9           if(result != TPM_RC_SUCCESS)
10              return result;
11      }
12      return TPM_RC_SUCCESS;
13  }
14
```

Marshaling of the TPML_DIGEST uses a similar scheme with a structure specifying the number of elements in an array and a subsequent call to a routine to marshal an array of that type.

```
1   UINT16
2   TPML_DIGEST_Marshal(TPML_DIGEST *source, BYTE **buffer, INT32 *size)
3   {
4       UINT16    result = 0;
5       result = (UINT16)(result + UINT32_Marshal((UINT32 *)&(source->count), buffer,
6                                                                                size));
7       result = (UINT16)(result + TPM2B_DIGEST_Array_Marshal(
8                                  (TPM2B_DIGEST *)(source->digests), buffer, size,
9                                  (INT32)(source->count)));
10
11      return result;
12  }
```

The marshaling code for the array is:

```
1   TPM_RC
2   TPM2B_DIGEST_Array_Unmarshal(TPM2B_DIGEST *target, BYTE **buffer, INT32 *size,
3                               INT32 count)
4   {
5       TPM_RC    result;
6       INT32 i;
7       for(i = 0; i < count; i++) {
8           result = TPM2B_DIGEST_Unmarshal(&target[i], buffer, size);
9           if(result != TPM_RC_SUCCESS)
10              return result;
11      }
12      return TPM_RC_SUCCESS;
13  }
```

 Copyright © TCG 2006-2020

9.10.6 TPM2B Handling

A TPM2B structure is handled as a special case. The unmarshaling code is similar to what is shown in 9.10.5 but the unmarshaling/marshaling is to a union element. Each TPM2B is a union of two sized buffers, one of which is type specific (the 't' element) and the other is a generic value (the 'b' element). This allows each of the TPM2B structures to have some inheritance property with all other TPM2B. The purpose is to allow functions that have parameters that can be any TPM2B structure while allowing other functions to be specific about the type of the TPM2B that is used. When the generic structure is allowed, the input parameter would use the 'b' element and when the type-specific structure is required, the 't' element is used.

When marshaling a TPM2B where the second member is a BYTE array, the size parameter indicates the size of the array. The second member can also be a structure. In this case, the caller does not prefill the size member. The marshaling code must marshal the structure and then back fill the calculated size.

Table xxx — Definition of TPM2B_EVENT Structure

Parameter	Type	Description
size	UINT16	Size of the operand
buffer [size] {:1024}	BYTE	The operand

```
1   TPM_RC
2   TPM2B_EVENT_Unmarshal(TPM2B_EVENT *target, BYTE **buffer, INT32 *size)
3   {
4       TPM_RC    result;
5       result = UINT16_Unmarshal((UINT16 *)&(target->t.size), buffer, size);
6       if(result != TPM_RC_SUCCESS)
7           return result;
8       // if size equal to 0, the rest of the structure is a zero buffer
9       //  so stop processing
10      if(target->t.size == 0)
11          return TPM_RC_SUCCESS;
12      if((target->t.size) > 1024)     // This check is triggered by the {:1024}
13                                      // notation on 'buffer'
14          return TPM_RC_SIZE;
15      result = BYTE_Array_Unmarshal((BYTE *)(target->t.buffer), buffer, size,
16                                    (INT32)(target->t.size));
17      if(result != TPM_RC_SUCCESS)
18          return result;
19      return TPM_RC_SUCCESS;
20  }
```

using these structure definitions:

```
1   typedef union {
2       struct {
3           UINT16        size;
4           BYTE          buffer[1024];
5       }             t;
6       TPM2B         b;
7   } TPM2B_EVENT;
```

Annex A
(informative)
Implementation Dependent

A.1 Introduction

This header file contains definitions that are used to define a TPM profile. The values are chosen by the manufacturer. The values here are chosen to represent a full featured TPM so that all of the TPM's capabilities can be simulated and tested. This file would change based on the implementation.

The file listed below was generated by an automated tool using three documents as inputs. They are:

1) The TCG_Algorithm Registery,

2) Part 2 of this specification, and

3) A purpose-built document that contains vendor-specific information in tables.

All of the values in this file have #ifdef 'guards' so that they may be defined in a command line.Additionally, TpmBuildSwitches.h allows an additional file to be specified in the compiler command line and preset any of these values.

Annex B
(informative)
Library-Specific

B.1 Introduction

This clause contains the files that are specific to a cryptographic library used by the TPM code.

Three categories are defined for cryptographic functions:

1) big number math (asymmetric cryptography),
2) symmetric ciphers, and
3) hash functions.

The code is structured to make it possible to use different libraries for different categories. For example, one might choose to use OpenSSL for its math library, but use a different library for hashing and symmetric cryptography. Since OpenSSL supports all three categories, it might be more typical to combine libraries of specific functions; that is, one library might only contain block ciphers while another supports big number math.

(informative)
Simulation Environment

C.1 Introduction

These files are used to simulate some of the implementation-dependent hardware of a TPM. These files are provided to allow creation of a simulation environment for the TPM. These files are not expected to be part of a hardware TPM implementation.

Annex D
(informative)
Remote Procedure Interface

D.1 Introduction

These files provide an RPC interface for a TPM simulation.

The simulation uses two ports: a command port and a hardware simulation port. Only TPM commands defined in TPM 2.0 Part 3 are sent to the TPM on the command port. The hardware simulation port is used to simulate hardware events such as power on/off and locality; and indications such as _TPM_HashStart.
