Change History

Revision 98

Added parameter to MemoryMove(), MemoryCopy(), and MemoryConcat() to make sure that the data being moved will fix into the receiving buffer

Change the size of local 2B buffers so that they are sized to the sum of the sizes of the elements rather than any other mathematical construct. This forces the size of the local buffer to track any changes to the sizes of the input components rather than have some assumed relationship.

Made multiple changes to code to eliminate “dead” code (code that could not be reached by any perturbation of the inputs).

Removed the “+” from the handle parameter in TPM2_HMAC_Start().

Changed TPM_RC_BAD_TAG to 0x01e so that its value would match TPM_BADTAG from 1.2

Changed reference implementation so that it would only allow use of default exponent for creation of RSA keys. It will allow other exponents for imported keys.

Changed _cpri__GenerateKeyRSA() in CpriRSA.c so that it no longer reads outside the bounds of an array when getting a value to use for encrypting/decrypting with a key, generated from a seed.

Removed TPM_NV_INDEX entity name space.

Authorization check includes locality.

Revision 99

Added phEnableNV to make NV enable independent of the platform hierarchy enable.

Added TPM2_PolicyNvWritten to permit a policy based on whether or not NV has been written

Added TPM_PT_NV_BUFFER_MAX, the maximum data size in an NV write.

Added define for HCRTM PCR, platform specific

Return code when an NV hierarchy is disabled is TPM_RC_HANDLE.

TPM2_Shutdown state may be nullified on any subsequent command.

CTR mode increments the entire IV, not just 32 bits.

TPM2_PolicySecret cannot have a null authHandle.

Revision 101

Added Definitions for Endorsement Authorization, Owner Authorization, Platform Authorization.

An error may change TPM state under certain conditions.

A restricted signing key cannot have a scheme of TPM_ALG_NULL.

Added TPMS_EMPTY.

 Copyright © TCG 2006-2020

TPM2_Sign: The signing scheme hash algorithm determines the size of the hash to be signed. However, this may be removed in a future revision.

TPM2_PCR_Allocate may return an error if the allocation fails.

Revision 103

Added ISO/IEC references and forward.

Handle errors always return TPM_RC_HANDLE, not TPM_RC_HIERARCHY.

TPM_PCR_Allocate does not change allocation for a bank not listed.

For a policy ticket, if expiration is non-negative, a NULL ticket is returned.

Revision 105

Added *lockoutPolicy.*

Added vendor-specific handles.

Added detection of a clock discontinuity to tickets.

Reworked TPM2_Import description.

Revision 107

Some reworking of H-CRTM, D-RTM.

Some clarification of policy expiration.

Changed references to ISO/IEC standards.

Change PPS, EPS Clear flush resident transient and persistent objects.

Revision 109

Any field upgrade preserves state, not just the standard commands.

Added TPM 2.0 Part 1 description of vendor-specific authorization values.

Refined description of PCR interaction with H-CRTM, TPM2_Startup, and locality. _TPM2_Hash_Start indicates the start of an H-CRTM sequence, not DRTM.

A non-authorization session must have at least one of encrypt, decrypt, or audit set

A policy session timeout can only change to a shorter value.

Added defines for ECC curves and removed some redundant values in the Part B annex.

TPM2_Sign can use a symmetric key.

TPM2_NV_UndefineSpace fails if TPMA_NV_POLICY_DELETE is set.

 Copyright © TCG 2006-2020

Revision 111

TPM2_ContextSave encrypts just the TPM2B_CONTEXT_SENSITIVE structure.

TPM 2.0 Part 2 structures removed algorithms and added notation referring to algorithm registry.

HMAC commands cannot be used with a restricted key.

Revision 113

Clarified Auth Role for hierarchies and NV Index.

Added password check to authorization checks.

Indicated that handles returned by the TPM are TPM_HT_TRANSIENT (three places).

Revision 115

FIPS 186-4 note.

Return codes for tag requires vs. actual mismatch.

Revision 117

A trial session cannot use encrypt or decrypt

HMAC is optional when the HMAC key is the Empty Buffer. If present, it must be correct.

CFB uses *sessionValue* in the KDF, not *sessionKey*

FIPS-140 requires NV to be erased when an Index is deleted. NV data must be initialized on a first partial write.

TPM2_Create for a keyed hash object must have TPM_ALG_NULL if *sign* and *decrypt* are both SET or CLEAR.

For an unrestricted HMAC key, if both the key and parameter have a non-NULL scheme, they must match.

Revision 119

Defined transient object and made the use of object and sequence object more consistent.

Refined the description of an exclusive audit session, the definition of auditReset, and its relationship to the audit attribute.

Explained that the TPM clock must be accurate even if there is no reliable external clock.

Updated the informative algorithm ID table.

TPM2_HMAC and TPM2_HMAC_Start return code change.

All signing commands, including attestation commands, return TPM_RC_KEY for a non-signing key.

TPM2_SetCommandCodeAuditStatus is not audited when used to change the algorithm.

 Copyright © TCG 2006-2020

Trial policy sessions check authorizations.

DA protection does apply to TPM_RH_LOCKOUT.

Revision 121

continueAuthSession is ignored for a password session.

Reworked NV attributes to accommodate more NV types. Defined TPM_NT.

For a hybrid counter Index, the first write always writes through to NV memory.

Added ECC point padding description.

Unmarshaling routines return error code, not bool. Detailed CommandDispatcher parameters. Unmarshal flag set means null is permitted.

The algorithm ID table in this specification is informative.

Context gap must be 2^^n-1.

Handle type 0x03 is for saved sessions, not active session.

Timeout is of length TPM2B_DIGEST, not UINT64.

nullProof can be used in a ticket.

TPM2_EncryptDecrypt uses an unrestricted key. The sign attribute is used as an encrypt attribute. A non-null mode cannot be overridden.

A TPM2_PolicySecret being satisfied by a policy requires a password or auth value. The object must permit password or HMAC authorization.

TPM2_PolicyNV is an immediate assertion.

Revision 122

NULL password can have continue set or clear.

Sign attribute becomes encrypt attribute for a symmetric cipher object.

Saved context metadata is normative. Encrypted data is vendor specific.

TPMU_SYM_MODE, TPMS_SCHEME_XOR selector permits NULL.

If the session requires a policy session, returns TPM_RC_AUTH_TYPE.

TPM2_NV_Certify returns TPM_RC_NV_UNINITIALIZED if unwritten even if size is zero.

Revision 123

Advised that callers should not use NV read public to calculate the Name.

Removed advice that FIPS may require an *authValue* size of half the hash algorithm digest size.

Clarified that *nonceTPM* is only used once in an HMAC calculation when the session is being used for both encrypt and decrypt.

Clarified that *authValue* is an Empty Buffer if a session is not an authorization session.

Clarified that *sessionValue* for authorization sessions that are encrypt or decrypt sessions is *sessionKey* || *authValue* regardless of binding.

Clarified that nameAlg is the *authPolicy* hash algorithm.

Structure definition lower limits apply to TPM inputs. Upper limits refer to inputs and outputs.

The year and day of year can indicate an errata date.

TPM_RC_NONCE is returned for a nonce value mismatch.

TPMS ALGORITHM_DETAIL_ECC kdf can be TPM_ALG_NULL.

TPMS_CONTEXT *savedHandle* indicates the context type.

If a handle in handle area references a session and the session is not present, returns TPM_RC_REFERENCE_H0 + N.

Clarified that the size of an encrypted parameter can be zero.

TPM2_Startup can result in the PCR update counter non-zero because of PCR resets.

For RSA salt key, the size of an encrypted salt must be the same as the size of the public modulus.

TPM2_ECDH_KeyGen requires *restricted* CLEAR and *decrypt* SET.

TPM2_Commit does not require the *sign* attribute.

TPM_PolicyOR extends the digest into a Zero Digest PolicyDigest. It does not replace the digest.

TPM2_PolicyPCR with a trial policy may use the TPM PCR if the caller does provide PCR settings.

TPM2_PolicyNV, TPM2_PolicyCounterTimer, TPM2_NV_Certify, can return TPM_RC_VALUE if the offset is greater than the data size.

Indicated that the reference implementation can do compare operations on a structure using a cast to a byte array, so unmarshaling code must initialize input buffers.

Revision 124

This revision begins to implement the NV PIN Index type. The information is incomplete and subject to change. It is included as a work in progress rather than create two forks to the specification.

Clarified that TPM2B_DATA is the size of a TPMT_HA but is not required to contain an algorithm ID.

Clarified that time can be set to zero at _TPM_Init or TPM2_Startup.

TPM2_StartAuthSession rejects a symmetric salt key.

Revision 125

 Copyright © TCG 2006-2020

Continued specifying NV PIN Index. The information is complete but not reviewed and still subject to significant changes.

Session-based encryption should support XOR, but a block cipher is platform specific.

Added TPM_PT_MODES for FIPS and other indications. Added TPMA_MODES.

Clarified the TPMA_STARTUP_CLEAR attribute (enable flags) settings on the various startup types.

_PRIVATE structure - changed from TPMT_SENSITIVE to TPM2B_SENSITIVE.

Revision 126

Reworded the PIN Index and rewrap text.

Added restrictions on *unique* input for TPM2_Create and TPM2_CreatePrimary.Removed obsolete TPM_CC_PP_FIRST and TPM_CC_PP_LAST.

Revision 127

Removed symmetric salt.

Revision 128

sensitiveDataOrigin is set for an asymmetric object.

Clarified that only the template *unique* field may be altered when an object is created.

A PIN index can be used in TPM2_PolicySecret if read or write locked.

ehProof is changed on TPM2_Clear.

TPM2_SetPrimaryPolicy requires a policy length consistent with the hash algorithm.

Revision 130

Augmented section 27.1 “Object Creation / Introduction” by adding the table “Creation Commands” and a description of that table.

Augmented section 27.6.1 “Entropy Creation / Introduction” by adding the table “Deriving Cryptographic Values” and a description of that table.

Added TPM2_PolicyTemplate(), TPM2_CreateLoaded(), TPMI_DH_PARENT.

Revision 131

Added TPM2_PolicyAuthorizeNV(), TPM2_EncryptDecrypt2().

Noted that TPM2_Create() may require transient resources.

TPM2_Clear() increments the *pcrUpdateCounter*, permitting a policy that can be invalidated on TPM2_Clear().

TPM_PT_NV_BUFFER_MAX returns the maximum size for NV read and NV certify as well as NV write,

 Copyright © TCG 2006-2020

Noted that TPMA_NV_POLICY_DELETE with a policy that cannot be satisfied defines an Index that can never be deleted.

TPM2_NV_Read ignores *offset* for bits and counter indexes.

Revision 132

Reworked Part 4 for refactored crypto code merge.

Added application note on audit alternative.

Added command code for PolicyAuthorizeNV and EncryptDecrypt2.

Added getcapability TPM_CAP_AUTH_POLICIES for hierarchy policies, and new structure TPMS_TAGGED_POLICY.

Offset is ignored when reading counter and bits NV indexes.

ReadClock can have audit session.

Revision 133

Added additional option to ticket expiration, and *timeEpoch*.

TPM2B_PRIVATE always has authorization value padded.

Clarified GPIO inputs and outputs.

EC Schnorr computation changes.

Salt always uses OAEP.

KDF must reject weak keys.

Revision 134

TPM2_Create for a *fixedParent* storage key only requires the symmetric algorithm of the parent and child to match.

Policy ticket creation also digests the *timeEpoch*.

Revision 135

Weak symmetric keys will not be generated and cannot be loaded.

OAEP uses the object's scheme. If the object's scheme is TPM_ALG_NULL, uses the objects Name algorithm.

GPIO input and output settings are platform or vendor specific.

Added a TPM2_Create, etc. reference code error check if data objects have *sensitiveDataOrigin* SET. The normative text was correct.

Revision 135 June 20

Modified the ECDAA signature calculation

Revision 136

Added PolicyAuthorize definition.

Noted that weak symmetric keys are not permitted.

OAEP uses the key's scheme unless it is NULL

Modifications to the ECDAA sign operation.

Parents use CFB mode, and cannot have a NULL symmetric algorithm

The salt key scheme must be NULL or OAEP.

Revision 137

Updated the interaction between nonceTPM and expiration.

data may be a non - Empty Buffer when a primary key is created.

TPM2_PolicySecret() referencing a PIN Pass Index returns a NULL ticket.

TPM2_SelfTest returns TPM_RC_FAILURE on failure.

phEnableNV is set on TPM Reset or TPM Restart

TPM2_Create and TPM2_CreatePrimary input is actually TPM2_PUBLIC even though the parameter says TPM2_TEMPLATE.

TPM2_PolicySecret for PIN and non-PIN Index clarifications.

TPM2_PolicyNV, TPM2_NV_Read, TPM2_NV_Certify may ignore offset parameter.

TPM2_NV_GlobalWriteLock, TPM2_NV_ReadLock may write NV.

Part 4 added SelfTest.h, Simulator_fp.h, removed CryptEccData.c,

Part 4 updated TPM2B structure sample.

Revision 138

Added back expiration comment that timeout cannot become smaller.

Explained the result of TPM_CAP_AUTH_POLICIES.

Removed obsolete CommandDispatcher.h and HandleProcess.h.

Revision 139

Revision 140

Added Attached Component (AC Send) description, structures, and functions.

TPM2_ECC_Parameters() may zero pad results.

TPM2_DictionaryAttackParameters does not reset failedTries.

Revision 141

Clarified that the KDFa 0x00 byte is only explicitly added if Label is not present or if it is not NULL-terminated.

Clarified that recoveryTIme may be tracked through a shutdown.

Added TDES annex explaining parity generation.

Revision 142

Code merge with 141.

Revision 143

Clarified HMAC key calculation for bound policy session with and without TPM2_PolicyAuthValue. Similar clarification for encrypted policy session.

Added the TPM2_MAC commands and merged with TPM2_HMAC commands. Added TPMI_ALG_MAC_SCHEME.

Changed TPM2B_TIMEOUT back to a UINT64.

TPM2_FlushContext for sessions ignores the upper byte of the handle.

Revision 144

Minor updates for TPM2_MAC.

Added TPMI_ALG_CIPHER_MODE, used for EncryptDecrypt.

Salt key must be a decrypt key.

seedValue is the size of the *nameAlg* digest.

Revision 145

More informative explanation. No normative changes.

Revision 146

Typos and fonts. No normative changes

Revision 147

Field upgrade should preserve the TPM vendor provisioned EKs.

Salt can only use asymmetric key encryption.

Alternative implementation of *failedTries* on non-orderly shutdown.

Added description of entropy usage for derived objects.

Alternate implementations for NV counter index initialization.

TPM_PT_NV_COUNTERS_MAX - zero value indicates no specified maximum.

Added TPMI_DH_SAVED for handle values that can be used in TPM2_ContextSave or TPM2_FlushContext.

TPMS_SCHEME_XOR cannot have a NULL hash algorithm

TPM2_PolicyTemplate() error codes if command is sent twice or if *cpHash* is already set.

CryptSym.h added to Part 4.

Revision 148

Reworked the attestation key certification to indicate that an encrypted challenge response is a more likely use case than an encrypted certificate.

Field upgrade should not affect TPM2_CreatePrimary() outputs under certain conditions.

The reset of the TIme circuit is related to TPM power, not TPM_Init.

MAX_SYM_DATA 128 changed from shall to should.

sign and decrypt both CLEAR or SET and scheme not TPM_ALG_NULL returns TPM_RC_SCHEME.

TPM2_PCR_Allocate() takes effect at _TPM_Init(), not TPM2_Startup().

Clarified in the text (the code was correct) that TPM2_PolicyDuplicationSelect() Names do not include the size.

The TPM may enter Failure mode if TPM2_Startup() is not TPM_SU_CLEAR after an algorithm set change that affects PCR banks. It was previously not a may.

After a field upgrade, preserving seeds, etc. was changed from shall to should.

Revision 149

Part 1 added phEnableNV to STATE_CLEAR_DATA, clearCount increments on TPM Restart, not TPM Resume

Noted that TPM2_EventSequenceComplete() always returns all hashes.

Noted that TPM2_PCR_Allocate() requirement for TPM_SU_CLEAR only applies until after the next _TPM_Init.

Part 4: For code merge: Added KdfTestData.h. Deleted BnEccData.c. Changed CryptDataEcc.c to CryptEccData.c

Revision 150

Added some notes about the interaction between audit and parameter encryption. Clarified that the audit digest is a single hash of *cpHash* and *rpHash*.

The random commit value has to be at least equal to the security strength of the signing key. KDFa for the commit calculation uses *vendorAlg*, not *nameAlg*.

+ decoration only applies to command parameters, not response parameters.

TPM2_Startup() does not clear the written bit for an orderly counter Index.

Removed CryptHashData.h.

Revision 151

TPM2_Hash() and TPM2_SequenceComplete() creates a ticket, with an Empty digest if in the NULL hierarchy.

TPM2_VerifySignature() returns a ticket with an Empty digest if the key is in the NULL hierarchy.

Updated ECC key generation and point padding in the Part 1 annex.

The TPM_PT_PS_REVISION value is platform specific.

Moved implementation specific description of the *Clock Safe* flag to an example.

Clarified that the getcapability returning TPML_PCR_SELECTION must return a selection for allocated banks but can return additional selections.

Revision 152

Added a first draft of TPM2_CertifyX509().

Revision 153

C.5 ECC Key Generation changed d to c and G to Q.

TPM2B_PRIVATE_KEY_RSA is permitted to be larger for *fixedTPM* keys. the TPM2B_PRIVATE structure in TPM2_Create() and TPM2_Load() may contain five CRT primes (instead of one).

Assign TPM_CC_CertifyX509 command code, x509Sign attribute, TPMA_X509_KEY_USAGE, Add TPM2_CertifyX509 description, parameters, and actions.

Define NV digest attestation structure, TPMS_NV_DIGEST_CERTIFY_INFO, and added certifying an NV digest to TPM2_NV_Certify.

Revision 154

Clarify that *label* in KDFa is an octet stream and the conditions for the KDFa zero byte.

Clarify the required size of an object sensitive area *seedValue* for TPM generated and imported objects.

Clarify that the L parameter in OAEP is a byte stream with the last byte zero, not a null terminated string.

Add an Annex with a Library Profile Guide.

Clarify that TPM_PT_NV_BUFFER_MAX applies to NV extend or NV certify.

The TPMA_X509_KEY_USAGE keyAgreeement and encipherOnly attributes require the decrypt attribute.

Explain that most of TPM2_SetAlgorithmSet is vendor-dependent.

Explain that the initialization of the list of commands requiring physical presence is platform-specific.

Revision 155

 Copyright © TCG 2006-2020

Part 2 removed , S AND <IO> from several table titles.

TPM_ECC_CURVE add + to TPM_ECC_NONE

Part 4 added files for X.509 support: OIDS.h, MinMax.h, and AC support: AC_spt.c

Changed Implementation.h to TpmProfile.h and added a pointer in TpmBuildSwitches.h to preset the values.

Revision 156

Added the ACT feature.

Explained that the TPM2_CertifyX509 *partialCertificate* and *addedToCertificate* are a DER encoded SEQUENCEs. Explained the encoding of the TPMA_OBJECT element. Noted that *tbsDigest* is returned as a debugging aid. Changed *qualifyingData* to *reserved* and that it must be an Empty Buffer.

Added a requirement that, if a command resets PCR in multiple banks, the PCR Update Counter must be incremented only once. If a command causes PCR in multiple banks to change, the PCR Update Counter must be incremented once for each bank.

Revision 157

Added the ACT code.

Revision 158

Minor updates to the ACT description.

Revision 159

Added several missing source code files to Part 4.

Reversed the TPMA_X509_KEY_USAGE bit map.

Acknowledgements

The writing of a specification, particularly a security specification, takes many hours for both development and review. This specification is no exception with roughly 100 individuals involved in the process. The TCG would like to acknowledge the contribution of those individuals (listed below) and the companies who allowed them to volunteer their time to the development of this specification.

The TCG would like to acknowledge the special contribution of David Wooten in the development of the TPM 2.0 architecture and documentation of this specification. We also acknowledge the generosity of Microsoft in contributing the code in this specification, written by David Wooten, Jiajing Zhu, and Paul England.

Special thanks are due to David Challener, David Wooten, Julian Hammersley, Graeme Proudler, and Ari Singer who served as Chair of the TPM Working Group at different times during the development of this specification.

The TCG would also like to give special thanks to David Grawrock, David Wooten, and Ken Goldman, who were the editors of this specification.

Trusted Platform Module Library

Part 1: Architecture

1 Scope

This specification defines the Trusted Platform Module (TPM) a device that enables trust in computing platforms in general. It is broken into parts to make the role of each part clear. All parts are required in order to constitute a complete standard

For a complete definition of all requirements necessary to build a TPM, the designer will need to use the appropriate platform-specific specification to understand all of the requirements for a TPM in a specific application or make appropriate choices as an implementer.

Those wishing to create a TPM need to be aware that this specification does not provide a complete picture of the options and commands necessary to implement a TPM. To implement a TPM the designer needs to refer to the relevant platform-specific specification to understand the options and settings required for a TPM in a specific type of platform or make appropriate choices as an implementer.

EXAMPLE The number of platform configuration registers and their attributes are not defined in this specification. Those values would be specified by a platform specific specification or alternatively determined by an implementer.

2 Specification Organization

This specification contains four parts, as follows. In normative clauses, text labeled NOTE or EXAMPLE are informative, non-normative. Text in Part 2 table columns Description or Comments are informative, non-normative.

TPM 2.0 Part 1: Architecture

TPM 2.0 Part 1 contains a narrative description of the properties, functions, and methods of a TPM. Unless otherwise noted, this narrative description is *informative*. TPM 2.0 Part 1 contains descriptions of some of the data manipulation routines that are used by this specification. The normative behavior for these routines is in C code in TPM 2.0 Part 3 and TPM 2.0 Part 4. Algorithms and processes described in this TPM 2.0 Part 1 may be made normative by reference from TPM 2.0 Part 2, TPM 2.0 Part 3, or TPM 2.0 Part 4.

TPM 2.0 Part 2: Structures

TPM 2.0 Part 2 contains a *normative* description of the constants, data types, structures, and unions for the TPM interface. Unless otherwise noted: (1) all tables and C code in TPM 2.0 Part 2 are normative, and (2) normative content in TPM 2.0 Part 2 takes precedence over any other part of this specification.

TPM 2.0 Part 3: Commands

TPM 2.0 Part 3 contains: (1) a *normative* description of commands, (2) tables describing the command and response formats, and (3) C code that illustrates the actions performed by a TPM. Within TPM 2.0 Part 3, command and response tables have the highest precedence, followed by the C code, followed by the narrative description of the command. TPM 2.0 Part 3 is subordinate to TPM 2.0 Part 2.

A TPM need not be implemented using the C code in TPM 2.0 Part 3. However, any implementation should provide equivalent or, in most cases, identical results as observed at the TPM interface or demonstrated through evaluation.

TPM 2.0 Part 4: Supporting Routines

TPM 2.0 Part 4 presents C code that describes the algorithms and methods used by the command code in TPM 2.0 Part 3. The code in TPM 2.0 Part 4 augments Parts 2 and 3 to provide a complete description of a TPM, including the supporting framework for the code that performs the command actions.

Any TPM 2.0 Part 4 code may be replaced by code that provides similar results when interfacing to the action code in TPM 2.0 Part 3. The behavior of TPM 2.0 Part 4 code not included in an annex is *normative*, as observed at the interfaces with TPM 2.0 Part 3 code. Code in an annex is provided for completeness, that is, to allow a full implementation of the specification.

NOTE This specification does not provide code for lower-level cryptographic algorithms and use of external libraries is required for a complete implementation.

Extensive modification of the code provided in TPM 2.0 Part 4 annexes is expected for any TPM implementation. Modifications are required in order to interface the TPM code with actual TPM hardware rather than the simulation framework provided. In addition, modifications of the code in TPM 2.0 Part 4 annexes would be necessary in order to meet the needs of applicable evaluation regimes.

4 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

4.1
“ATH”
sequence of four octets of data containing 41 54 48 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.2
“CFB”
sequence of four octets containing 43 46 42 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.3
“DUPLICATE”
sequence of 10 octets containing 44 55 50 4C 49 43 41 54 45 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.4
“IDENTITY”
sequence of nine octets containing 49 44 45 4E 54 49 54 59 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.5
“OBFUSCATE”
sequence of 10 octets containing 4F 42 46 55 53 43 41 54 45 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.6
“SECRET”
sequence of seven octets containing 53 45 43 52 45 54 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.7
“STORAGE”
sequence of eight octets containing 53 54 4F 52 41 47 45 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

4.8
“XOR”
sequence of four octets containing 58 4F 52 00_{16} that is used as a label in a KDF

NOTE See 11.4.10.2 for justification for the terminating octet of 00_{16}.

 Copyright © TCG 2006-2020

4.9
ancestor
<object loaded in a TPM> Storage Key that was required to have been loaded prior to loading an object

4.10
authValue
octet string containing a value that is used for access authorization. The value is used as a password or to derive a key for an HMAC calculation.

4.11
authPolicy
digest value produced by an execution of policy commands and used for access authorization

4.12
bound
authValue of the Object is not included in the HMAC authorization for the authorization session

4.13
canonical form
data structure in the format used for transport to and from the TPM (see 4.36)

4.14
CLEAR
bit with a value of zero (0), or the action of causing a bit to have a value of zero (0)

4.15
command
discrete TPM function that is exposed externally and recognizable by a TPM's command processor; also, the values sent to the TPM to indicate the operation to be performed

4.16
commandCode
numeric identifier of the operation to be performed by a TPM

4.17
context
collection of data that provides qualifying information about a data object to differentiate it from others of the same type or to differentiate one version of a data object from another

4.18
cpHash
hash of the command code, Object names, and parameters of a command

4.19
Derivation Parent
loadable key used to derive other keys; a TPM_ALG_KEYEDHASH Parent Key

4.20
descendant
<Storage Key> Object whose loading is conditional on a specific Storage Key having been previously loaded

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

4.21
digest
result of a hash operation

4.22
duplicate
allowing a Protected Object created by a TPM to be used on a different TPM

4.23
ECDH
Diffie-Hellman secure secret sharing process using elliptic curve operations

4.24
entity
a hierarchy, PCR, object, or NV Index in a TPM shielded location

4.25
Ephemeral Key
key created as part of a protocol that is not used again after the protocol is complete

4.26
Empty Auth
Empty Buffer used as an authorization value

4.27
Empty Buffer
sized array with no data; indicated by a size field of zero followed by an array containing no elements

4.28
Empty Digest
Empty Buffer used as a digest

4.29
Empty Point
ECC point with Empty Buffers for both the x and y coordinates

4.30
Empty Policy
Empty Buffer used when a policy value is required; as a *policyValue*, an Empty Buffer will satisfy no policy

NOTE No policy can be satisfied by an Empty Policy because an Empty Policy has zero length but a *policyDigest* is the size of a hash digest and a digest is never zero length.

4.31
Endorsement Authorization
authorization using either *endorsementAuth* or *endorsementPolicy*

 Copyright © TCG 2006-2020

4.32
Extend
Extended
operation that replaces the current value of a digest with the hash of a buffer constructed by concatenating new data (normally a digest) to the current value of the digest (see 11.4.8)

4.33
External Object
Object that may be loaded into a TPM without being a member of a specific hierarchy

4.34
Failure mode
mode in which the TPM returns TPM_RC_FAILURE in response to all commands except TPM2_GetTestResult() or TPM2_GetCapability()

4.35
import
operation that allows a Protected Object not created by a TPM to be incorporated into a hierarchy of the TPM

4.36
internal form
data structure using a layout that is specific to an implementation that may or may not be the same as the canonical form

4.37
Lockout Authorization
Authorization using either *lockoutAuth* or *lockoutPolicy*

4.38
LSB0
little-endian
the least-significant octet of a datum is at byte offset 0

4.39
MSB0
big-endian
the most-significant octet of a datum is at byte offset 0

4.40
LSb0

the least-significant bit of a datum is assigned the bit number of 0

4.41
MSb0
the most-significant bit of a datum is assigned the bit number of 0

4.42
non-volatile
data that is retained even when power is removed

 Copyright © TCG 2006-2020

4.43
NULL
context-sensitive value that, when applied to a pointer, is a system-defined value indicating that the pointer does not reference data; and, when applied to a structure identified by an algorithm identifier, is the TPM_ALG_NULL value indicating that no additional data is present

4.44
NULL Password
NULL Auth
authorization where the authorization value is the Empty Buffer, resulting in an authorization that is a sequence of 9 octets containing either 40 00 00 09 00 00 00 00_{16} or 40 00 00 09 00 00 01 00 00_{16}

4.45
NULL Signature
signature with the TPM_ALG_NULL signature scheme that contains no data

4.46
NULL-terminated
sequence of non-zero values followed by a value containing zero; most often a NULL-terminated string where the values are ASCII-encoded octets

4.47
NULL Ticket
ticket structure with *tag* set to a value that is correct for the context, *hierarchy* is TPM_RH_NULL, and *digest* is an Empty Buffer

4.48
NV Index
Index
user defined non-volatile shielded location

4.49
Object
key or data that has a public portion and, optionally, a sensitive portion; and which is a member of a hierarchy

NOTE An NV Index is not an object.

4.50
octet
eight bits of data

NOTE On most modern computers, this is the smallest addressable unit of data.

4.51
orderly shutdown
when the TPM has completed TPM2_Shutdown() before power to the TPM is removed or _TPM_Init is asserted

4.52
ordinary key
key produced with a seed taken from the TPM RNG

cf. Primary Key

4.53
Owner Authorization
authorization using either *ownerAuth* or *ownerPolicy*

4.54
Parent Key
any object with the *decrypt* and *restricted* attributes SET and the *sign* attribute CLEAR

NOTE There are two types of parent keys: Storage Parent and Derivation Parent.

4.55
PCR
one or more platform configuration registers each containing a digest

4.56
PCR.alg
hash algorithm associated with a specific PCR

4.57
PCR bank
collection of PCR identified by a hash algorithm, with each PCR in the bank containing a digest computed using the bank identifier's hash algorithm

4.58
PCR.digest
digest value associated with a specific PCR

4.59
Permanent Entity
TPM resource with an architecturally defined handle that does not change

Note The value of a Permanent Entity may change

4.60
Persistent Entity
TPM resource created by a Protected Capability that persists in TPM memory across power cycles and TPM resets

4.61
Platform Authorization
authorization using either *platformAuth* or *platformPolicy*

4.62
policyDigest
digest uniquely representing an ordered set of policy commands and operands; used to determine if a policy authorizing an action has been satisfied

4.63
policySession→cpHash
policy session context value that, if not the Empty Buffer, is the *cpHash* value that the authorized command is required to have for the authorization to be valid

4.64
PolicyAuthorize Command
either TPM2_PolicyAuthorize() or TPM2_PolicyAuthorizeNV()

4.65
platform firmware
code added to the platform by its manufacturer that is needed for booting and proper platform operation

NOTE Commonly, but not exclusively, referred to as BIOS or UEFI or SMM code

4.66
Primary Key
key derived from a Primary Seed that is associated with the hierarchy of the Primary Seed

cf. ordinary key

4.67
Primary Object
Primary Key or a data blob with a sensitive area that is encrypted using a symmetric key derived from the public area of the object and a Primary Seed

4.68
private area
encrypted and integrity protected blob that contains the sensitive area of an object

4.69
Primary Seed
large random value contained within a TPM from which Primary Keys and Primary Objects are derived

4.70
Protected Capability
operation performed by the TPM on data in a Shielded Location in response to a command sent to the TPM

4.71
Protected Object
object with an encrypted sensitive portion, the sensitive portion of which the TPM will only decrypt when it is in a Shielded Location

4.72
RAM
memory that may be accessed in any order and which has no endurance limitations

 Copyright © TCG 2006-2020

4.73
reset interval
period between two successive TPM Resets and the interval during which the *resetCount* is not changed

4.74
response
values returned by the TPM when it completes processing of a command

4.75
Resume PCR
platform configuration register with a value that is preserved over a TPM Resume sequence

4.76
Root of Trust
component that must always behave in the expected manner because its misbehavior cannot be detected

NOTE The complete set of Roots of Trust has at least the minimum set of functions to enable a description of the platform characteristics that affect the trustworthiness of the platform.

4.77
rpHash
hash of the response code and the parameters of a response

4.78
Sealed Data Object
encrypted, user-defined, data blob that is associated with a hierarchy and loaded using TPM2_Load() or TPM2_CreatePrimary()

4.79
sensitive area
contain the confidential or secret parts of an object that are required to be encrypted and integrity protected when not in a Shielded Location on a TPM

4.80
sequence object
transient data structure used to hold hash state that has a handle and may be context swapped

NOTE See clause 30

4.81
session
transient TPM structure that maintains the state associated with a sequence of authorizations or an audit digest

4.82
SET
bit with a value of one (1), or the action of causing a bit to have a value of one (1)

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

4.83
Shielded Location
location on a TPM that contains data that is shielded from access by any entity other than the TPM and which may be operated on only by a Protected Capability

4.84
Shutdown(CLEAR)
abbreviated form of the command TPM2_Shutdown() with the *startupType* parameter set to TPM_SU_CLEAR

4.85
Shutdown(STATE)
abbreviated form of the command TPM2_Shutdown() with the *startupType* parameter set to TPM_SU_STATE

4.86
sizeof(x)
operator that returns the number of octets in the operand 'x'

4.87
Startup(CLEAR)
abbreviated form of the command TPM2_Startup() with the *startupType* parameter set to TPM_SU_CLEAR

4.88
Startup(STATE)
abbreviated form of the command TPM2_Startup with the *startupType* parameter set to TPM_SU_STATE

4.89
Storage Key
key used to provide integrity and confidentiality protection for descendant keys that are stored off of the TPM

4.90
Storage Parent
Storage Key that is acting as a parent key

4.91
Temporary Object
Objects that become unusable after a TPM Reset and that may not be converted into Persistent Objects

4.92
temporary resource
data object created during the execution of a command that does not persist in TPM memory after the command completes

4.93
TPM_GENERATED_VALUE
32-bit number (FF 54 43 47_{16}) that is used to tag structures that are generated by a TPM

 Copyright © TCG 2006-2020

4.94
TPM Reset
resetting of all TPM internal state to default values due to Startup(CLEAR)

4.95
TPM Resource Manager
TRM
software executing on a system with a TPM that ensures that the resources necessary to execute TPM commands are present in the TPM

4.96
TPM Restart
Startup(CLEAR) that initializes all PCR but preserves most other TPM state from the previous Shutdown(STATE)

4.97
TPM Resume
Startup(STATE) that initializes some PCR but preserves most TPM state from the previous Shutdown(STATE)

4.98
transient object
object or sequence object that may be explicitly loaded and unloaded from TPM memory by the TRM; cleared from TPM memory when the TPM is initialized (TPM2_Startup())

4.99
transient resource
object, sequence object, or session that may be explicitly loaded and unloaded from TPM memory by the TRM; cleared from TPM memory when the TPM is initialized (TPM2_Startup())

4.100
Trusted Platform Module
TPM
implementation of this specification

4.101
user-installable software
any software that may be installed on a platform other than platform firmware

4.102
volatile data
data that is lost when power is removed

4.103
Zero Digest
non-zero-length digest with all octets set to zero

5 Symbols and Abbreviated Terms

5.1 Symbols

For the purposes of this document, the following symbol definitions apply unless the text is in the `Courier` font.

A || B	concatenation of B to A
$\lceil x \rceil$	the smallest integer not less than x
$\lfloor x \rfloor$	the largest integer not greater than x
A ≔ B	assignment of the results of the expression on the right (B) to the parameter on the left
A = B	equivalence (A is the same as B)
{ A }	an optional element
A ⊕ B	bitwise exclusive OR of elements
A & B	logical AND of elements
A | B	the logical OR of elements
{A | B}	selection of elements
{A : B}	an inclusive range of elements between A and B
<A, B, … >	an ordered list of elements (a tuple)
0…0	a context-sensitive number of octets of zero
F()	denotes a function **F**
F(*p* == *x*)	denotes a function or TPM command **F** with parameter *p* set to value *x*
length(*x*)	denotes a function that returns the number of significant bits in an integer value *x*
H()	denotes the hash function
[*n*]*P*	multiplication of point *P* by the integer value *n*
A • B	multiplication of two integer values A and B
A→B	denotes a reference to element B within structure A
A mod B	A modulus B

Text in the **`Courier`** font indicates code written according to the C language standard.

5.2 Abbreviations

For the purposes of this document, the following abbreviations apply.

Abbreviation	Description
TPM	Prefix for an indication passed from the system interface of the TPM to a Protected Capability defined in this specification
AK	Attestation Key
BIOS	Basic Input/Output System
CA	Certificate Authority
CFB	Cipher Feedback mode

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

Abbreviation	Description
CPU	Central Processing Unit
CRTM	Core Root of Trust for Measurement
CTR	Counter mode
D-RTM	dynamic RTM
DA	dictionary attack
DoS	Denial of Service
DRBG	Deterministic Random Bit Generator
DSA	Digital Signature Algorithm
EA	Enhanced Authorization
EAL	evaluated assurance level
ECDAA	ECC-based Direct Anonymous Attestation
ECDH	Elliptic Curve Diffie-Hellman
EK	Endorsement Key
EPS	Endorsement Primary Seed
FIPS	Federal Information Processing Standard
FUM	Field Upgrade mode
GPIO	General Purpose I/O
HMAC	Hash Message Authentication Code
I/O	Input/Output
IV	Initialization Vector
KDF	key derivation function
KVT	known value test
LPC	Low Pin Count
LSb	Least Significant bit
LSO	Least Significant Octet
MSb	Most Significant bit
MSO	Most Significant Octet
NIST	National Institute of Standards and Technology
NP	new parent
NV	non-volatile
NVRAM	Non-Volatile Random Access Memory
OAEP	Optimal Asymmetric Encryption Padding
OEM	Original Equipment Manufacturer
OIAP	Object-Independent Authorization Protocol
OID	Object Identifier in ASN.1 format
OSAP	Object-Specific Authorization Protocol
PCR	platform configuration register(s)

Abbreviation	Description
POST	Power On Self-Test
PP	Physical Presence
PPS	Platform Primary Seed
PRF	Pseudo-Random Function
PRNG	Pseudo-Random Number Generator
PSS	Probabilistic Signature Scheme
QN	Qualified Name
RNG	Random Number Generator
RSA	Rivest, Shamir and Adleman
RTM	Root of Trust for Measurement
RTR	Root of Trust for Reporting
RTS	Root of Trust for Storage
S-RTM	Static RTM
SHA	Secure Hash Algorithm
SMAC	Symmetric block cipher Message Authentication Code
SMM	System Management Mode
SPS	Storage Primary Seed
SRK	Storage Root Key
TBB	Trusted Building Block
TCB	Trusted Computing Base
TCG	Trusted Computing Group
TPM	Trusted Platform Module
TPM2_	Prefix for a command defined in this specification
TSS	TCG Software Stack
UEFI	Unified Extensible Firmware Interface

 Copyright © TCG 2006-2020

6 Compliance

Unless the TPM 2.0 Part 3 general description of a command indicates that the command is mandatory, a compliant TPM need not implement the command. However, if implemented, the command is required to have the behavior defined in TPM 2.0 Part 3. A platform-specific specification will indicate the commands from this specification that are required to be implemented in order to be compliant with that platform-specific specification.

The code in this specification is a reference implementation that describes required TPM behavior as observed from the TPM interface. The C-code may be reorganized or rewritten in any desired implementation language and remain compatible with this specification as long as the observable behavior is equivalent.

Even though the code in the reference implementation has undergone extensive testing, it is likely that some errors exist and one or more of those errors could lead to a TPM failure or exploit. Regardless of any other statement about normative behavior, one should not assume that a TPM exploit or failure is an intended behavior. It is not necessary to reproduce such a behavior in order to be compliant with this specification.

NOTE Please report bugs in the reference code to the TCG (admin@trustedcomputinggroup.org) so that the reference code may be brought into compliance with the specification.

The response codes in the specification are normative. An implementation performing a check prescribed by this specification is required to return the indicated error if the check fails. The order in which checks are performed is not normative. This means that a command with multiple errors could return different response codes on different TPMs. However, the response code returned is required to be the normative response code used to indicate the specific failure.

Capacities and algorithms of a TPM implementation may vary from the reference implementation; in this case, the same error would not occur in the same situation (such as, a TPM implementation with more memory may be able to satisfy a request where the reference implementation would have returned an error). However, these differences should not cause a different response code to be returned when the nature of the error is the same as in the reference implementation.

TPM 2.0 Part 4 of the specification contains major subsystems that may change for each instance of a TPM. For example, the NV subsystem of the reference implementation is not representative of the actual implementation of most physical NV implementations but is a crude analog. When the subsystem is rewritten, an equivalent interface should be provided, and the errors returned are required to match those of the reference implementation.

NOTE A constraint on the design of the TPM was the process of compliance-testing of different TPM implementations. If a TPM implementation has modularity similar to the reference implementation, then TPM tests that assume a modular design will be able to produce reliable test results on each TPM implementation.

The reference implementation uses static and stack-based allocation of resources and does not do allocations on a heap. However, a TPM implementation may use heap-based memory management in which case some error conditions and codes will differ. These differences are limited, and the allowed response codes and error conditions are defined in 39.3.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

7 Conventions

7.1 Bit and Octet Numbering and Order

An integer value is considered to be an array of one or more octets. The octet at offset zero within the array is the most significant octet (MSO) of the integer. Bit number 0 of that integer is its least significant bit and is the least significant bit in the last octet in the array.

EXAMPLE A 32-bit integer is an array of four octets; the MSO is at offset [0], and the most significant bit is bit number 31. Bit zero of this 32-bit integer is the least significant bit in the octet at offset [3] in the array.

NOTE 1 Array indexing is zero-based.

NOTE 2 This definition does not match the "network bit order" used in many IETF documents, such as RFC 4034. In those documents, the most significant bit of a datum has the lowest bit number. It is conventional practice to send that bit first when using a serial network protocol, and the bits are numbered in the order in which they are sent. This specification numbers bits according to the power of two to which they correspond within a datum. This numbering corresponds to the normal convention for bit numbering in hardware registers that hold integer values rather than fixed-point numbers.

NOTE 3 The TPM uses MSB0, LSb0 numbering.

The first listed member of a structure is at the lowest offset within the structure and the last listed member is at the highest offset within the structure.

For a character string (letters delimited by ""), the first character of the string contains the MSO.

7.2 Sized Buffer References

The specification makes extensive use of a data structure called a *sized buffer*. A sized buffer has a size field followed by an array of octets equal in number to the value in the size field.

The structure will have an identifying name. When the specification references the size field of the structure, the structure name is followed by ".size" (a period followed by the word "size"). When the specification references the octet array of the structure, the structure name is followed by ".buffer" (a period followed by the word "buffer").

7.3 Numbers

Numbers are decimal unless a different radix is indicated.

Unless the number appears in a table intended to be machine readable, the radix is a subscript following the digits of the number. Only radix values of 2 and 16 are used in this specification.

Radix 16 (hexadecimal) numbers have a space separator between groups of two hexadecimal digits.

EXAMPLE 1 $40\ FF\ 12\ 34_{16}$

Radix 2 (binary) numbers use a space separator between groups of four binary digits.

EXAMPLE 2 $0100\ 1110\ 0001_{2}$

The number of digits indicates the number of bits in the representation.

EXAMPLE 3 20_{16} is a hexadecimal number that contains exactly 8 bits and has a decimal value of 32.

EXAMPLE 4 $10\ 0000_{2}$ is a binary number that contains exactly 6 bits and has a decimal value of 32.

EXAMPLE 5 $0\ 20_{16}$ is a hexadecimal number that contains exactly 12 bits and has a decimal value of 32.

A number in a machine-readable table may use the “0x” prefix to denote a base 16 number. In this format, the number of digits is not always indicative of the number of bits in the representation.

EXAMPLE 6 0x20 is a hexadecimal number with a value of 32, and the number of bits is determined by the context.

8 Changes from Previous Versions

This version of the TPM specification introduces these additional features to the TPM family:

- Definition of an interface that allows variability of underlying cryptographic algorithms – TPM 1.2 is constrained by its data structures to using RSA and SHA1. The TPM 2.0 structure and interface defines support for a wide range of hash and asymmetric algorithms along with limited support for use of various block, symmetric ciphers. Of particular note is the addition of support for the elliptic curve (ECC) family of asymmetric algorithms.
- Unification of authorization methods – TPM 1.2 has different schemes to authorize the use, delegated use, and migration of objects. This 2.0 specification provides a uniform framework for using authorization capabilities, so they may be combined in unique ways to provide more flexibility.
- Expansion of authorization methods – TPM 2.0 allows authorization with clear-text passwords and Hash Message Authentication Code (HMAC). It also allows construction of an arbitrarily complex authorization policy for an object using multiple authorization qualifiers.
- Dedicated BIOS support – TPM 2.0 adds a Storage hierarchy controlled by platform firmware, letting the OEM benefit from the cryptographic capabilities of the TPM regardless of the support provided to the OS.
- Simplified control model – TPM 2.0 needs no special provisioning process to be useful to applications. Although objects on which the TPM operates may have limitations, all commands are available all the time. This lets application developers rely on TPM capabilities being available whenever a TPM is present.

A TPM compatible with this specification need not be compatible with previous TPM specifications.

This specification defines the operations a TPM performs and the structures used for communication between the TPM and the host system. It does not define an electrical interface to the TPM, nor does it specify which subset of TPM 2.0 commands and resources are required for a specific platform. Please refer to platform-specific TPM specifications for this information.

9 Trusted Platforms

9.1 Trust

In the context of Trusted Computing Group (TCG) specifications, “trust” is meant to convey an expectation of behavior. However, predictable behavior does not necessarily constitute behavior that is worthy of trust. For example, we expect that a bank will behave like a bank, and we expect that a thief will behave like a thief.

In order to determine the expected behavior of a platform, it is necessary to determine its identity as it relates to the platform behavior. Physically different platforms may have identical behavior. If they are constructed of components (hardware and software) that have identical behavior, then their trust properties should be the same.

The TCG defines schemes for establishing trust in a platform that are based on identifying its hardware and software components. The Trusted Platform Module (TPM) provides methods for collecting and reporting these identities. A TPM used in a computer system reports on the hardware and software in a way that allows determination of expected behavior and, from that expectation, establishment of trust.

9.2 Trust Concepts

9.2.1 Trusted Building Block

A trusted building block (TBB) is a component or collection of components required to instantiate a Root of Trust. Typically, platform-specific, a TBB is part of a Root of Trust that does not have Shielded Locations.

One example of a TBB is the combination of the CRTM, the connection between CRTM storage and a motherboard, the path between CRTM storage and the CPU, the connection between the TPM and a motherboard, and the path between the CPU and the TPM. This combination comprises the Root of Trust for Reporting (RTR).

A TBB is a component that is expected to behave in a way that does not compromise the goals of trusted platforms.

9.2.2 Trusted Computing Base

A trusted computing base (TCB) is the collection of system resources (hardware and software) that is responsible for maintaining the security policy of the system. An important attribute of a TCB is that it be able to prevent itself from being compromised by any hardware or software that is not part of the TCB.

The TPM is not the trusted computing base of a system. Rather, a TPM is a component that allows an independent entity to determine if the TCB has been compromised. In some uses, the TPM can help prevent the system from starting if the TCB cannot be properly instantiated.

9.2.3 Trust Boundaries

The combination of TBB and Roots of Trust form a trust boundary, within which measurement, storage, and reporting may be accomplished for a minimal configuration. In systems that are more complex, it may be necessary for the CRTM to establish trust in other code, by making measurements of that other code and recording the measurement in a PCR. If the CRTM transfers control to that other code regardless of the measurement, then the trust boundary is expanded. If the CRTM will not run that code unless its

 Copyright © TCG 2006-2020

measurement is the expected value, the trust boundary remains the same because the measured code is an expected extension of the CRTM.

9.2.4 Transitive Trust

Transitive trust is a process whereby the Roots of Trust establish the trustworthiness of an executable function, and trust in that function is then used to establish the trustworthiness of the next executable function.

Transitive trust may be accomplished either by: (1) knowing that a function enforces a trust policy before it allows a subsequent function to take control of the TCB, or (2) using measurements of subsequent functions so that an independent evaluation may establish the trust. The TPM may support either of these methods.

9.2.5 Trust Authority

When the RTM begins to execute the CRTM, the entity that may vouch for the correctness of the TBB is the entity that created the TBB. For typical systems, this is the platform manufacturer. In other words, the manufacturer is the authority on what constitutes a valid TBB, and its reputation is what allows someone to trust a given TBB.

As the system transitions to code outside the CRTM, the transitive trust chain is maintained by measurement of that code. If execution of that code is conditional on its measurement, then the authority for that code remains unchanged. That is, if the platform manufacturer's CRTM does not run code outside the CRTM unless that code has a specific measured value, then the platform manufacturer remains the trust authority regardless of who provided that code.

In modern architectures, where firmware and software components come from many different suppliers, it is often not feasible for platform manufacturers to know the signers of all code that runs on a platform. Therefore, they may not remain the authority on platform state for very long. The measurements recorded in the RTS then determine the chain of authority for the current system state.

Two different methods allow evaluation of the trust authority for a platform.

1) Code is measured (hashed), and its value is recorded in the RTS. If the code is run regardless of its measurement, then the authority for the trust is the digest of the code reported by the RTR. That is, the measurements speak for themselves, and the verifier needs either to have knowledge of the measurements that constitute trustworthy code or knowledge of the measurements that indicates malicious or vulnerable code.
2) Code is signed so that the identity of the authority for the code is known. If this identity is recorded in the RTS, the evaluation can be changed. Instead of being based on knowing the digest of the code, it can be based on identities of the signers of the code.

Because trusted sources of code may sometimes produce code with security vulnerabilities, support for revocation is often required. To allow revocation of specific code modules, it is often necessary to use a hybrid solution where both authorities and details are recorded. This simplifies the process of determining whether a module from a specific vendor has been revoked.

NOTE If the code is measured (hashed) and not signed, it is harder to know if a specific measurement is valid unless there is a centralized database of all known digests of revoked code. When the identity of the authority is known, one can contact the vendor to determine if it has revoked code with a given hash.

 Copyright © TCG 2006-2020

9.3 Trusted Platform Module

A TPM is a system component that has state that is separate from the system on which it reports (the host system). The only interaction between the TPM and the host system is through the interface defined in this specification.

TPMs are implemented on physical resources, either directly or indirectly. A TPM may be constructed using physical resources that are permanently and exclusively dedicated to the TPM, and/or using physical resources that are temporarily assigned to the TPM. All of a TPM's physical resources may be located within the same physical boundary, or different physical resources may be within different physical boundaries.

Some TPMs are implemented as single-chip components that are attached to systems (typically, a PC) using a low-performance interface (such as, Low Pin Count, or LPC). The TPM component has a processor, RAM, ROM, and Flash memory. The only interaction with these TPMs is through the LPC bus. The host system cannot directly change the values in TPM memory other than through the I/O buffer that is part of the interface.

Another reasonable implementation of a TPM is to have the code run on the host processor while the processor is in a special execution mode. For these TPMs, parts of system memory are partitioned by hardware so that the memory used by the TPM is not accessible by the host processor unless it is in this special mode. Further, when the host processor switches modes, it always begins execution at specific entry points. This version of a TPM would have many of the same attributes as the stand-alone component in that the only way for the host to cause the TPM to modify its internal state is with well-defined interfaces. There are several different schemes for achieving this mode switching including System Management Mode, Trust Zone™, and processor virtualization.

Definition of the interaction between the host and the TPM is the primary objective of this specification. Prescribed commands instruct the TPM to perform prescribed actions on data held with the TPM. A primary purpose of these commands is to allow determination of the trust state of a platform. The ability of a TPM to accomplish its objective depends on the proper implementation of Roots of Trust.

9.4 Roots of Trust

TCG-defined methods rely on Roots of Trust. These are system elements that must be trusted because misbehavior is not detectable. The set of roots required by the TCG provides the minimum functionality necessary to describe characteristics that affect a platform's trustworthiness.

While it is not possible to determine if a Root of Trust is behaving properly, it is possible to know how roots are implemented. Certificates provide assurances that the root has been implemented in a way that renders it trustworthy. For example, a certificate may identify the manufacturer and evaluated assurance level (EAL) of a TPM. This certification provides confidence in the Roots of Trust implemented in the TPM. In addition, a certificate from a platform manufacturer may provide assurance that the TPM was properly installed on a machine that is compliant with TCG specifications so that the Root of Trust provided by the platform may be trusted (see 9.5.2 for more information on certification).

The TCG requires three Roots of Trust in a trusted platform:

- Root of Trust for Measurement (RTM),
- Root of Trust for Storage (RTS), and
- Root of Trust for Reporting (RTR).

Trust in the Roots of Trust can be achieved through a variety of means but is anticipated to include technical evaluation by competent experts.

 Copyright © TCG 2006-2020

9.4.1 Root of Trust for Measurement (RTM)

The RTM sends integrity-relevant information (measurements) to the RTS. Typically, the RTM is the CPU controlled by the Core Root of Trust for Measurement (CRTM). The CRTM is the first set of instructions executed when a new chain of trust is established. When a system is reset, the CPU begins executing the CRTM. The CRTM then sends values that indicate its identity to the RTS. This establishes the starting point for a chain of trust (see 9.5.5 for a more detailed description of integrity measurement).

9.4.2 Root of Trust for Storage (RTS)

The TPM memory is shielded from access by any entity other than the TPM. Because the TPM can be trusted to prevent inappropriate access to its memory, the TPM can act as an RTS.

Some of the information in TPM memory locations is not sensitive and the TPM does not protect it from disclosure. An example of non-sensitive data is the current contents of a platform configuration register (PCR) containing a digest. Other information is sensitive and the TPM does not allow access to the information without proper authority. An example of sensitive data in a Shielded Location is the private part of an asymmetric key.

Sometimes, the TPM uses the contents of one Shielded Location to gate access to another Shielded Location. For example, access to (use of) a private key for signing may be conditioned on PCR having specific values.

9.4.3 Root of Trust for Reporting (RTR)

9.4.3.1 Description

The RTR reports on the contents of the RTS. An RTR report is typically a digitally signed digest of the contents of selected values within a TPM.

NOTE Not all Shielded Locations are directly accessible. For example, the values of the private part of keys and authorizations are in Shielded Locations on which the TPM will not report.

The values on which the RTR reports typically are

- evidence of a platform configuration in PCR (such as, TPM2_Quote()),
- audit logs (such as, TPM2_GetCommandAuditDIgest ()), and
- key properties (such as, TPM2_Certify()).

The interaction between the RTR and RTS is critical. The design and implementation of this interaction should mitigate tampering that would prevent accurate reporting by the RTR. An instantiation of the RTS and RTR will

- be resistant to all forms of software attack and to the forms of physical attack implied by the TPM's Protection Profile, and
- supply an accurate digest of all sequences of presented integrity metrics.

9.4.3.2 Identity of the RTR

The TPM contains cryptographically verifiable identities for the RTR. The identity is in the form of asymmetric aliases (Endorsement Keys or EKs) derived from a common seed. Each seed value and its aliases should be statistically unique to a TPM. That is, the probability of two TPMs having the same EK should be insignificant.

 Copyright © TCG 2006-2020

The seed may be used to generate multiple asymmetric keys, all of which would represent the same TPM and RTR.

9.4.3.3 RTR Binding to a Platform

The TPM reports on the state of the platform by quoting the PCR values. For assurance that these PCR values accurately reflect that state, it is necessary to establish the binding between the RTR and the platform. A Platform Certificate can provide proof of this binding. The Platform Certificate is assurance from the certifying authority of the physical binding between the platform (the RTM) and the RTR.

9.4.3.4 Platform Identity and Privacy Considerations

The uniqueness of an EK and its cryptographic verifiability raises the issue of whether direct use of that identity could result in aggregation of activity logs. Analysis of the aggregated activity could reveal personal information that a user of a platform would not otherwise approve for distribution to the aggregators.

To counter undesired aggregation, TCG encourages the use of domain-specific signing keys and restrictions on the use of an EK. The Privacy Administrator controls use of an EK, including the process of binding another key to the EK.

NOTE Privacy Administrator's control of the EK differs from Owner control of the RTS providing separation of the security and identity uses of the TPM.

Unless the EK is certified by a trusted entity, its trust and privacy properties are no different from any other asymmetric key that can be generated by pure software methods. Therefore, by itself, the public portion of the EK is not privacy sensitive.

9.5 Basic Trusted Platform Features

9.5.1 Introduction

At a minimum, a trusted platform provides the three Roots of Trust described previously. All three roots use certification and attestation to provide evidence of the accuracy of information. A trusted platform will also offer Protected Locations (see 10.3) for the keys and data objects entrusted to it. Finally, a trusted platform may provide integrity measurement to ensure the trustworthiness of a platform by logging changes to platform state; this is done by recording logged entries in PCR for later validation as being correct and unaltered. These basic TPM concepts are now described in detail.

9.5.2 Certification

The nominal method of establishing trust in a key is with a certificate indicating that the processes used for creating and protecting the key meets necessary security criteria. A certificate may be provided by shipping the TPM with an embedded key (that is, an Endorsement Key) along with a Certificate of Authenticity for the EK. The EK and its certificate may be used to associate credentials (certificates) with other TPM keys; this process is described in 9.5.3.3. When a certified key has attributes that let it sign TPM-created data, it may attest to the TPM-resident record of platform characteristics that affect the integrity (trustworthiness) of a platform.

NOTE The EK does not have to be installed when the TPM is shipped. At the factory, an EK may be generated from the Endorsement Seed and a Certificate of Authenticity created for that EK. The EK does not have to be permanently installed in the TPM. When the TPM is in possession of a customer, the customer may, at their discretion, have the TPM use the Endorsement Seed and recreate the EK for which they have a Certificate of Authenticity.

 Copyright © TCG 2006-2020

9.5.3 Attestation and Authentication

9.5.3.1 Types of Attestation

Trusted platforms employ a hierarchy of attestations:

1) An external entity attests to a TPM in order to vouch that the TPM is genuine and complies with this TPM specification. This attestation takes the form of an asymmetric key embedded in a genuine TPM, plus a credential that vouches for the public key of that pair.

NOTE 1 A credential that is used to vouch for the embedded asymmetric key is commonly called an "Endorsement Certificate."

2) An external entity attests to a platform in order to vouch that the platform contains a Root-of-Trust-for-Measurement, a genuine TPM, plus a trusted path between the RTM and the TPM. This attestation takes the form of a credential that vouches for information including the public key of the asymmetric key pair in the TPM.

NOTE 2 A credential used to vouch for the platform is commonly called a "Platform Certificate."

3) An external entity called an "Attestation CA" attests to an asymmetric key pair in a TPM in order to vouch that a key is protected by an unidentified but genuine TPM and has particular properties. This attestation takes the form of a credential that vouches for information including the public key of the key pair. An Attestation CA typically relies upon attestations of type 1 and 2 in order to produce attestation of type 3.

NOTE 3 The credential created by the CA is commonly called an "Attestation Key Certificate."

4) A trusted platform attests to an asymmetric key pair in order to vouch that a key pair is protected by a genuine but unidentified TPM and has particular properties. This attestation takes the form of a signature signed by the platform's TPM over information that describes the key pair, using an attestation-key protected by the TPM, plus attestation of type 3 that vouches for that attestation key.

NOTE 4 This type of attestation is done using TPM2_Certify().

5) A trusted platform attests to a measurement in order to vouch that a particular software/firmware state exists in a platform. This attestation takes the form of a signature over a software/firmware measurement in a PCR using an attestation key protected by the TPM, plus attestation of type 3 or 4 for that attestation key.

NOTE 5 This is type of attestation is commonly called a "quote" and is done with TPM2_Quote().

6) An external entity attests to a software/firmware measurement in order to vouch for particular software/firmware. This attestation takes the form of a credential that vouches for information including the value of a measurement and the state it represents.

NOTE 6 This is commonly called "third-party certification."

Attestation of types 3 and 4 entail the use of a key to sign the contents of Shielded Locations. An Attestation Key (AK) is a particular type of signing key that has a restriction on its use, in order to prevent forgery (the signing of external data that has the same format as genuine attestation data). The restriction is that an AK may be used only to sign a digest that the TPM has created. If an AK is known to be protected by a TPM (by virtue of attestation of type 3 or 4), it may be relied on to report accurately on Shielded Location content, and not sign externally provided data that appears to be valid and TPM-produced but is not.

 Copyright © TCG 2006-2020

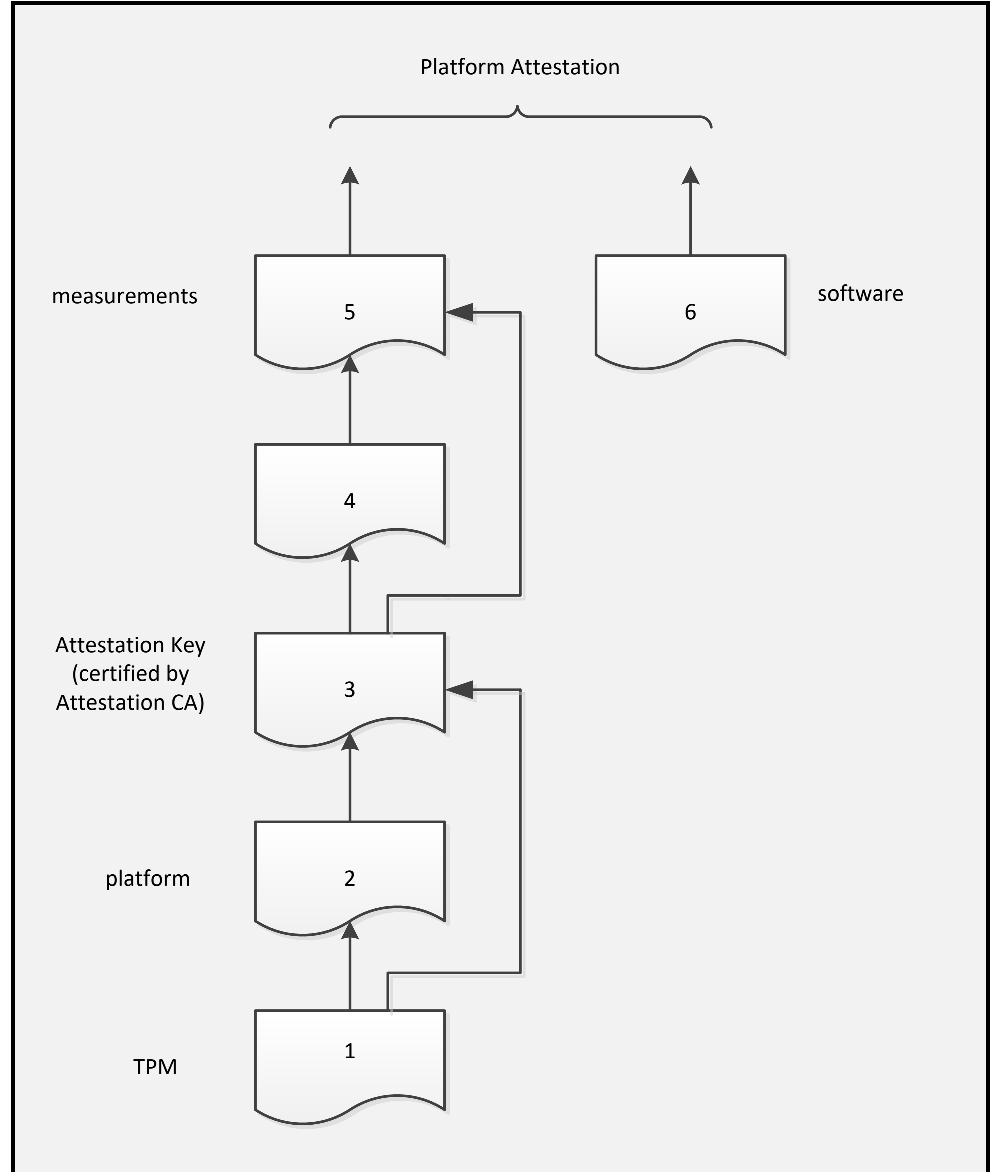

Figure 1 — Attestation Hierarchy

9.5.3.2 Attestation Keys

When the TPM creates a message to sign from internal TPM state (such as, in TPM2_Quote()), a special value (TPM_GENERATED_VALUE) is used as the message header. A TPM-generated message always begins with this value.

When the TPM digests an externally provided message, it checks the first few octets of the message to ensure that they do not have the same value as TPM_GENERATED_VALUE. When the digest is complete, the TPM produces a ticket that indicates the message did not start with TPM_GENERATED_VALUE. When an AK is used to sign the digest, the caller provides the ticket so that the TPM can determine that the message used to create the digest was not a possible forgery of TPM attestation data.

NOTE The digest in the ticket must match the digest being presented to the AK for signing.

EXAMPLE If an attacker produced a message block that was identical to a TPM-generated quote, that message block would start with TPM_GENERATED_VALUE to indicate that it is a proper TPM quote. When the TPM performs a digest of this block, it notes that the first octets are the same as TPM_GENERATED_VALUE. It will not generate the ticket indicating that the message is safe to sign, so an AK may not be used to sign this digest. Similarly, an entity checking an attestation made by an AK must verify that the message signed begins with TPM_GENERATED_VALUE in order to verify the message is indeed a TPM-generated quote.

Values signed by an AK may be assured to reflect TPM state, but AKs may also be used for general signing purposes.

An AK does not have much value to a remote challenger if the AK cannot be associated with the platform that it represents. This association is made using the identity certification process.

9.5.3.3 Attestation Key Identity Certification

Any TPM user that can create a key on a TPM can create a restricted-use signing key. The key creator may then ask a third party, such as an attestation Certificate Authority (CA), to provide a certificate for it. The attestation CA may request that the caller provide some evidence that the key being certified is a TPM-resident key.

Evidence of TPM residency may be provided using a previously generated certificate for another key on the same TPM. An EK or Platform Certificate may provide this evidence.

NOTE 1 There is no requirement that certificates come only from an attestation CA. The method described above is an example of a scheme that may be used when privacy is required.

If a certified key may sign, it may be used to certify that some other object is resident on the same TPM. This allows the new AK to be linked to a certified key. A CA may use the certification from the TPM to produce a traditional certificate for the new key.

If the certified key is a decryption key and may not sign, then an alternative method is used to allow the new key or data object to be reliably certified. For this alternative certification, the identity of the Object to be certified and a certificate for the decryption key (such as, an EK) are provided to the CA. From the certificate, the CA determines the public key for the decryption key. The CA then produces a challenge for the Object to be certified and encrypts the challenge with the certified key. The encrypted challenge is given to the TPM containing both the certified decryption key and the key to be certified.

The challenge is protected using methods that are dependent on the type of the certified decryption key. The general method is described in clause 24. Additional methods appropriate to RSA keys are described in B.10.4 and additional methods appropriate to ECC key are in C.6.4. The protection process produces an encrypted blob, an HMAC over the blob, and a secret value that can only be recovered by the certified decryption key.

TPM2_ActivateCredential() is used to access the challenge. The TPM recovers the secret value and uses it to generate the keys necessary to decrypt and validate the HMAC and encrypted blob. If the challenge is recovered successfully, and the key being certified by the credential is loaded on the TPM, then the challenge is returned to the caller, and then provided to the CA. After the CA validates the challenge, it can issue the certificate for the key

NOTE 3 The protection process used for the challenge is almost identical to the process used for key import. In order to make sure that there is no misuse of the encrypted structures, an application-specific value is used in the key recovery process. In the case of a challenge, the label "IDENTITY" is used in the KDF that generates the keys (symmetric and HMAC) from the seed value.

TPM2_ActivateCredential() can operate on any Object. The choice of attributes for an Object to be certified is at the discretion of the CA. Because a unique identifier for the Object is included in the integrity

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

hash, the TPM enforces the challenge's accessibility only if the Object matches the criteria set by the CA as expressed in the object identifier.

9.5.4 Protected Location

When the sensitive portion of an object is not held in a Shielded Location on the TPM, it is encrypted. When encrypted, but not on the TPM, it is not protected from deletion, but it is protected from disclosure of its sensitive portions. Wherever it is stored, it is in a Protected Location.

Objects in long-term protected storage need to be loaded into the TPM for use. The application that created the objects manages their movement from long-term storage to the TPM.

Since a TPM has limited memory, it may be unable to hold all objects required by all applications simultaneously. The TPM supports swapping of object contexts by a TPM Resource Manager (TRM) so that the TPM can service these multiple applications. The object contexts are encrypted before being returned to the TRM by the TPM. If the object is needed later, the TRM can reload the context into the TPM providing a cache-like behavior.

Encryption of Protected Locations uses multiple seeds and keys that never leave the TPM. One of these is the Context Key. It is a symmetric key used to encrypt data when it is temporarily swapped out of the TPM so that a different working set of objects may be loaded. Other sensitive values that never leave the TPM are the Primary Seeds. These seeds are the root of the storage hierarchies that protect objects that are retained by applications. A Primary Seed is a random number used to generate protection keys for other objects; these objects may be Storage Keys that contain protection keys that are then used to protect still more objects.

Primary Seeds may be changed, and when they are changed, the objects they protected will no longer be usable. For example, the Storage Primary Seed (SPS) creates the Storage hierarchy for owner-related data, and that seed changes when the owner changes.

9.5.5 Integrity Measurement and Reporting

The Core Root of Trust for Measurement (CRTM) is the starting point of measurement. This process makes the initial measurements of the platform that are Extended into PCR in the TPM. For measurements to be meaningful, the executing code needs to control the environment in which it is running, so that the values recorded in the TPM are representative of the initial trust state of the platform.

A power-on reset creates an environment in which the platform is in a known initial state, with the main CPU running code from some well-defined initial location. Since that code has exclusive control of the platform at that time, it may make measurements of the platform from firmware. From these initial measurements, a chain of trust may be established. Because this chain of trust is created once when the platform is reset, no change of the initial trust state is possible, so it is called a static RTM (S-RTM).

An alternative method of initializing the platform is available on some processor architectures. It lets the CPU act as the CRTM and apply protections to portions of memory it measures. This process lets a new chain of trust start without rebooting the platform. Because the RTM may be re-established dynamically, this method is called dynamic RTM (D-RTM). Both S-RTM and D-RTM may take a system in an unknown state and return it to a known state. The D-RTM has the advantage of not requiring the system to be rebooted.

An integrity measurement is a value that represents a possible change in the trust state of the platform. The measured object may be anything of meaning but is often

- a data value,

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

- the hash of code or data, or
- an indication of the signer of some code or data.

The RTM (usually, code running on the CPU) makes these measurements and records them in RTS using Extend. The Extend process (see 17.2) allows the TPM to accumulate an indefinite number of measurements in a relatively small amount of memory.

The digest of an arbitrary set of integrity measurements is statistically unique, and an evaluator might know the values representing particular sequences of measurements. To handle cases where PCR values are not well known, the RTM keeps a log of individual measurements. The PCR values may be used to determine the accuracy of the log, and log entries may be evaluated individually to determine if the change in system state indicated by the event is acceptable.

Implementers play a role in determining how event data is partitioned. TCG's platform-specific specifications provide additional insight into specifying platform configuration and representation as well as anticipated consumers of measurement data.

Integrity reporting is the process of attesting to integrity measurements recorded in a PCR. The philosophy behind integrity measurement, logging, and reporting is that a platform may enter any state possible — including undesirable or insecure states — but is required to accurately report those states. An independent process may evaluate the integrity states and determine an appropriate response.

10 TPM Protections

10.1 Introduction

This part of the specification describes the protections provided by the Trusted Platform Module. This clause describes the properties of selected capabilities and selected data locations for a TPM that has been evaluated according to a Protection Profile and a TPM that has not been modified by physical means.

TPM protections are based on the concepts of Protected Capabilities and Protected Objects. A Protected Capability is an operation that must be performed correctly for a TPM to be trusted. A Protected Object is data (including keys) that must be protected for a TPM operation to be trusted. Protected Objects in the TPM reside in Shielded Locations; the TPM may manipulate the contents of Shielded Locations only by using Protected Capabilities. Protected Objects outside Shielded Locations have their integrity and confidentiality protected cryptographically.

Since a Protected Object may reside outside of Shielded Location protections, the definition of “access” to a Protected Object denotes disclosure of its contents, not modification. Such objects are not protected against loss or tampering. However, before loading a Shielded Location with an outside object, the TPM will use a secure hash function to validate that the object was properly protected and not altered. If the integrity check fails, the TPM returns an error and does not load the object.

The only operations on Shielded Locations of a TPM are the Protected Capabilities defined in this specification and the vendor-specific operations that meet the requirements of 10.4.

10.2 Protection of Protected Capabilities

A Protected Capability may be modified only by other Protected Capabilities in the same TPM. Thus, the process of updating TPM firmware is required to be a Protected Capability.

10.3 Protection of Shielded Locations

As noted, access to any data on a TPM requires use of a Protected Capability. Therefore, all information on a TPM is in a Shielded Location. The contents of a Shielded Location are not disclosed unless the disclosure is intended by the definition of the Protected Capability. A TPM is not allowed to export data from a Shielded Location other than by using a Protected Capability.

NOTE Data in an I/O buffer that can be modified by the host is not “on” the TPM, even though the I/O buffer may be shielded from access while the TPM is processing a command or generating a response.

10.4 Exceptions and Clarifications

Vendor-specific operations may access and modify Shielded Locations on a TPM under the following circumstances.

- A vendor-specific operation may use the standard TPM authorization mechanism.
- A vendor-specific capability may read any TPM-resident structure that is not required to be in a Shielded Location at all times if the usage of that structure is authorized per the structure’s authorization mechanism.

EXAMPLE A vendor-specific command may use the public portion of a key. If the key is a user key, no authorization would be required.

 Copyright © TCG 2006-2020

NOTE Among other things, the exception above enables access to a Shielded Location, so the structure's access authorization may be checked.

- Vendor-specific operations may use a sequence of Protected Capabilities.
- Vendor-specific operations may use the standard TPM command interface or use a vendor-defined interface.

These clarifications serve to approve specific legitimate interpretations of the requirements.

- A vendor-specific operation that takes advantage of exceptions and clarifications to the "protection" requirements should be defined as part of the security target of the TPM. Such a vendor-specific command or capability should be evaluated to determine whether it meets Platform-specific TPM and System Security Targets.
- If a TPM stores vendor-specific cipher-text that is protected against subversion to the same or greater extent as internal TPM-resources stored outside the TPM with TCG-defined methods, then that cipher-text does not require protection from physical attack. If the TPM stores only vendor-specific cipher-text that does not require protection from physical attack, that location may be excluded from analysis when determining whether the TPM complies with the "physical protection" requirements specified by TCG.
- If a TPM uses external memory for non-volatile storage of TPM state (including seeds and proof values), movement of the TPM state to and from the NV memory constitutes a vendor-defined operation that is allowed by this specification. The protection profile of that TPM should include a description of the protections of that data to ensure confidentiality and integrity of the data and to mitigate against rollback attacks.

11 TPM Architecture

11.1 Introduction

This clause describes the overall operation of the TPM and the functional units required for its operation. The major elements of the architecture are shown in Figure 2.

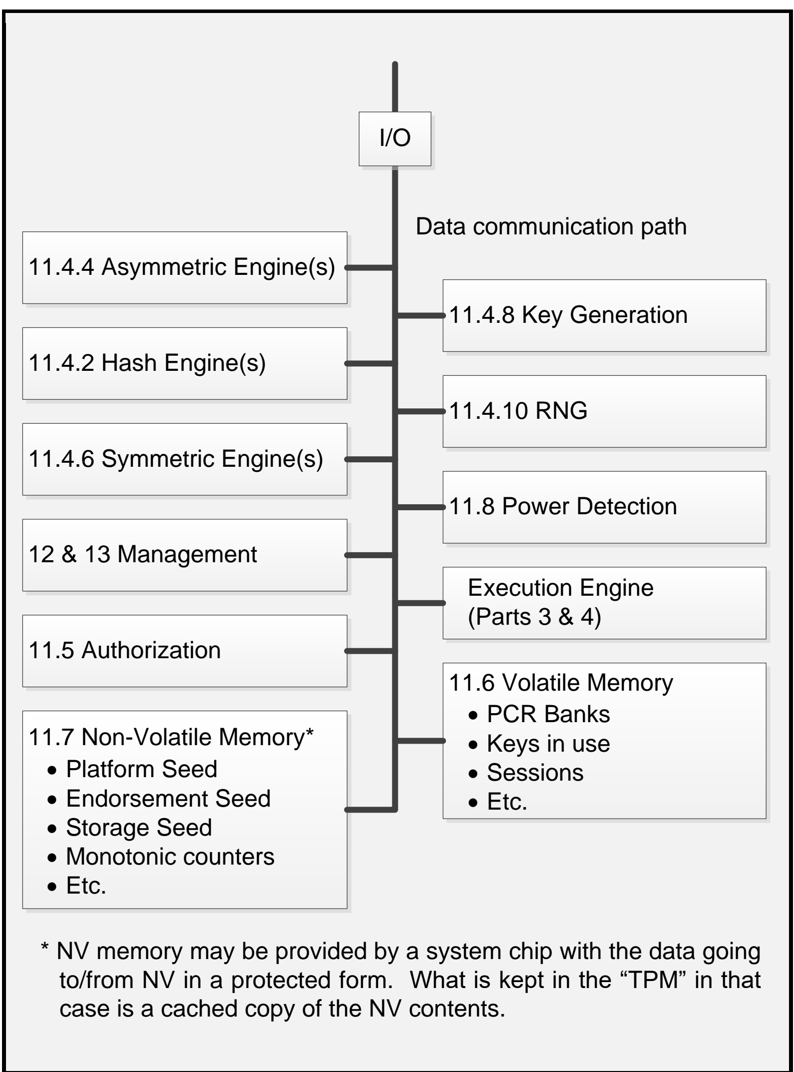

Figure 2 — Architectural Overview

11.2 TPM Command Processing Overview

Figure 3 is a high-level flow diagram for a TPM command. The figure shows only the normal flow for a command that executes successfully. The tabs on a box indicate the name of the module performing the operation. Additional details for each of the modules shown in Figure 3 are in this clause and in clauses dedicated to those modules.

The partitioning of functions in Figure 3 is illustrative and not normative.

 Copyright © TCG 2006-2020

The flow assumes that the command has been placed in an input buffer that is accessible to the Execute Command module (this name is used because of its similarity to the ExecCommand() function in the reference code that performs the functions illustrated here).

NOTE 1 The mechanism for getting the command into the TPM buffer and providing the command-available indication is specific to each physical interface and is defined in interface-specific documents.

The command structure includes a standard header (see 18) that Execute Command validates. It then determines if the command requires access to any Shielded Location that is identified by a handle. If so, it calls the Handle module to verify that the handle references the right type of resource for the command and that the resource is currently loaded on the TPM.

When control returns to Execute Command, it checks the *tag* parameter in the command header to determine if authorization values are provided. If so, Authorizations is called to validate that each of the authorizations is correct. The authorizations are associated with a handle value, so the authorization is specific to a particular entity.

After validating the authorizations, Execute Command calls Command Dispatch to unmarshal the remaining command parameters and validate that the required parameters of the required type are present. All parameters are validated to meet the requirements of its data type as defined in TPM 2.0 Part 2 even if the parameter will subsequently be discarded because of optional behavior of a command.

After unmarshaling the parameters, Command Dispatch calls the command-specific library function to execute the specific command. Additional parameter checking may be required in the command-specific actions.

The command processing is structured so that changes to the TPM state do not occur until the TPM can validate that the command parameters are correct and that the resources necessary to complete the command are available. Only then will it make irreversible changes to the TPM state. This structuring ensures that when the TPM returns an error, the TPM will be in the same state as before command actions modified the data in any Shielded Location.

NOTE 2 Requiring that the TPM retain its state minimizes the interference between applications and helps prevent system instability due to careless use of the TPM by applications.

There are several classes of operations that return an error but may change TPM state.

- An authorization failure may update the dictionary attack mechanism.
- The self test mechanism has state (for example, which algorithms have been tested) that is considered to be different from the command execution state. Changes to this state may occur regardless of the command return code. For example, an implicit self test invoked to test an algorithm required by the command may mark the algorithm as tested.
- If a self test fails, the TPM will go into Failure Mode.

When the command actions are complete, the Command Dispatch marshals response parameters into the output buffer. If the command had authorizations, Acknowledge is called to construct acknowledge session values for the response.

If the command encounters an error, the response packet will contain a code that is characteristic of the error and, when possible, an indication of whether the error was associated with a handle, an authorization session, or a command parameter. No additional qualifying data is present. In most cases, the error code and parameter location value suffice to isolate the problem.

NOTE 3 In the case of a self-test failure, the TPM response code is not sufficient to diagnose the problem. Therefore, a reporting scheme is provided so that the failure cause can be read. However, error report contents vary by vendor and are not standardized. There is thus no need to standardize self-test response codes because no standard remediation is possible for most self-test failures.

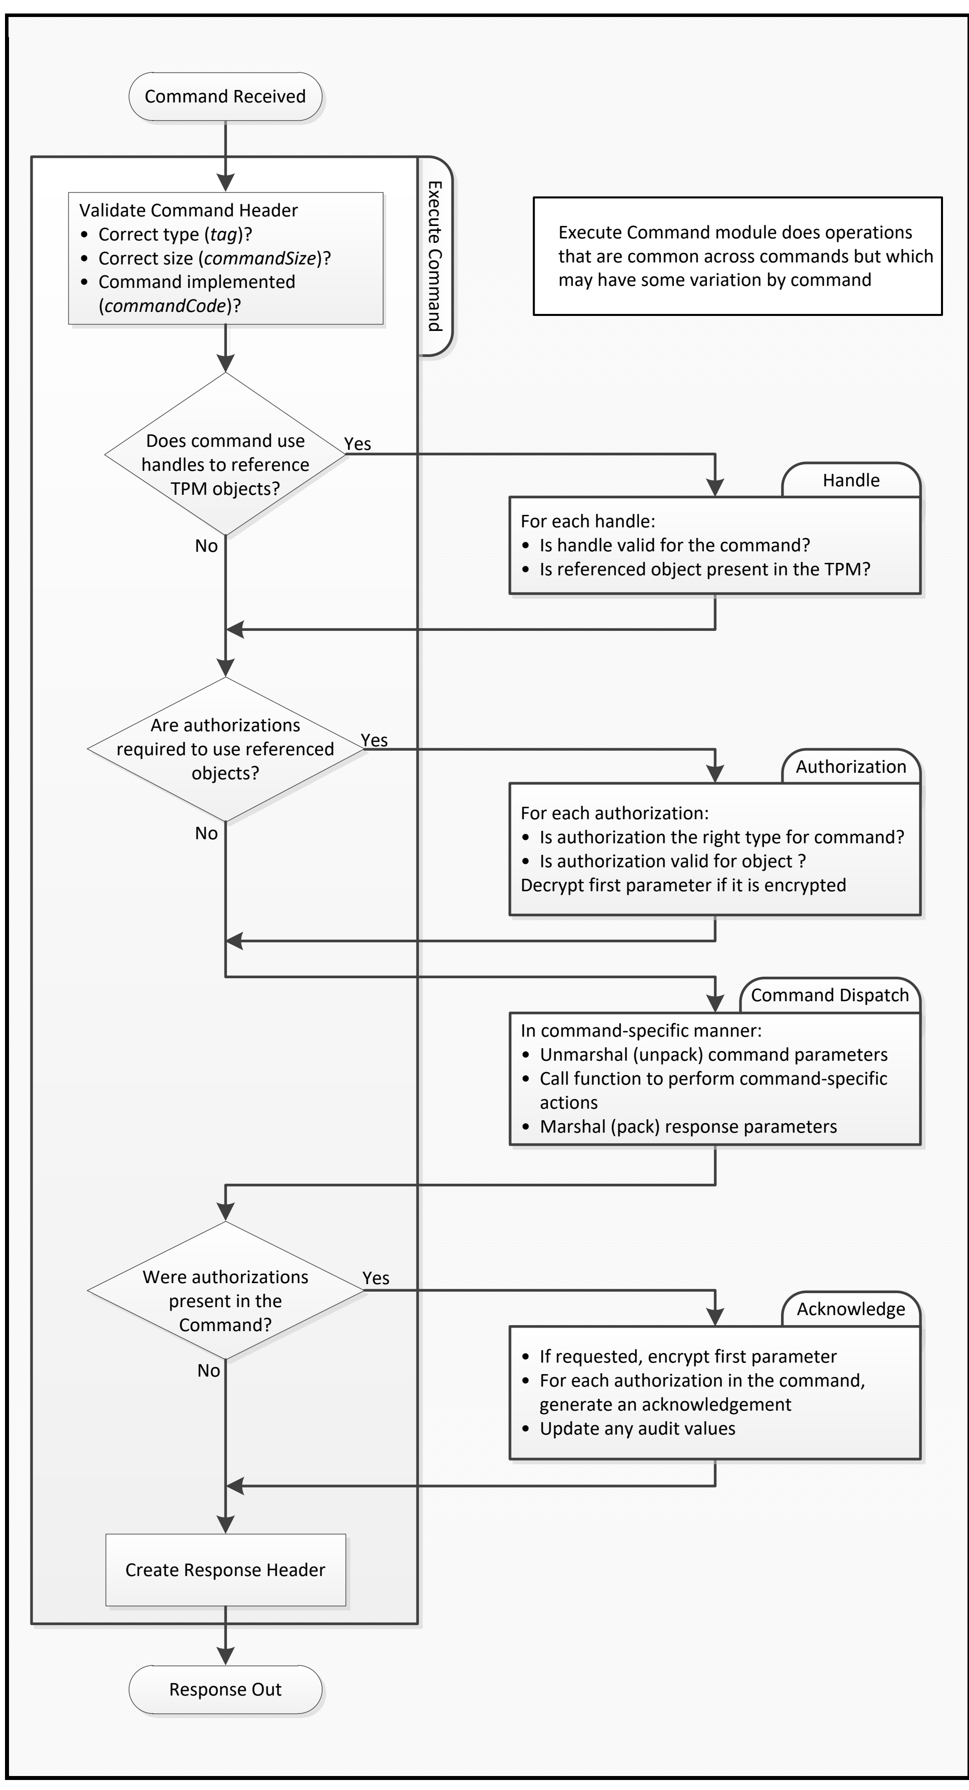
November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

After constructing the response, including acknowledge sessions, the TPM indicates to the interface that the response is ready to be returned.

The TPM command/response structure is described in Clause 17.10 (see clause 19 for a description of the methods for creating the values that authorize use of a TPM Shielded Location and clause 39 for response code formatting information).

During the processing of these commands, the TPM uses other modules that the following parts of this clause will describe.

 Copyright © TCG 2006-2020



Command Received
Execute Command
Validate Command Header
• Correct type (tag)?
• Correct size (commandSize)?
• Command implemented (commandCode)?
Execute Command module does operations that are common across commands but which may have some variation by command
Does command use handles to reference TPM objects?
Yes
No
Handle
For each handle:
• Is handle valid for the command?
• Is referenced object present in the TPM?
Are authorizations required to use referenced objects?
Yes
No
Authorization
For each authorization:
• Is authorization the right type for command?
• Is authorization valid for object ?
Decrypt first parameter if it is encrypted
Command Dispatch
In command-specific manner:
• Unmarshal (unpack) command parameters
• Call function to perform command-specific actions
• Marshal (pack) response parameters
Were authorizations present in the Command?
Yes
No
Acknowledge
• If requested, encrypt first parameter
• For each authorization in the command, generate an acknowledgement
• Update any audit values
Create Response Header
Response Out

Figure 3 — Command Execution Flow

11.3 I/O Buffer

The I/O buffer is the communications area between a TPM and the host system. The system places command data in the I/O buffer and retrieves response data from the buffer.

A description of the physical processes used to move I/O buffer data to/from the system is beyond the scope of this specification. Platform-specific working groups within the TCG produce the specifications for the physical interfaces to the TPM on their platforms. Those specifications detail the interactions between system software and the TPM I/O buffer.

There is no requirement that the I/O buffer be physically isolated from other parts of the system. It can be a shared memory. However, when processing of a command begins, the implementation must ensure that the TPM is using the correct values. For example, if the TPM performs a hash of the command data as part of the authorization processing, the TPM needs to protect the validated command data from modification. That is, before the data is validated, it is required to be protected from modification. Before the data is modified, it is required to be in a Shielded Location.

11.4 Cryptography Subsystem

11.4.1 Introduction

The Cryptography subsystem implements the TPM's cryptographic functions. It may be called by the Command Parsing module, the Authorization Subsystem, or the Command Execution module. The TPM employs conventional cryptographic operations in conventional ways. These operations include

- hash functions,
- asymmetric encryption and decryption,
- asymmetric signing and signature verification,
- symmetric encryption and decryption,
- symmetric signing (HMAC and SMAC) and signature verification, and
- key generation.

The remainder of this clause describes some algorithms usually found in a TPM to show how they are handled. These descriptions illustrate, but do not limit, the choice of available algorithms.

11.4.2 Symmetric Block Cipher MAC Algorithms

The TPM may implement Symmetric Block Cipher Message Authentication Code (SMAC).

An SMAC is a form of symmetric signature over some data using a symmetric block cipher algorithm. It provides assurance that protected data was not modified and that it came from an entity with access to a key value. To have usefulness in protecting data, the key value needs to be a secret or a shared secret.

11.4.3 Hash Functions

Hash functions may be used directly by external software or as the side effect of many TPM operations. The TPM uses hashing to provide integrity checking and authentication as well as one-way functions, as needed (such as, KDF).

A TPM should implement an approved hash algorithm that has approximately the same security strength as its strongest asymmetric algorithm.

EXAMPLE An ECC with a 384-bit key has a security strength of 192 bits. SHA384, with 192 bits of security, would meet the preceding requirement above.

NOTE The TCG may create sets of algorithms that do not have the same security strength for the hash and asymmetric algorithms.

A hash function will be denoted by $\mathbf{H}_{algorithm}()$ with the algorithm subscript indicating the hash algorithm or the parameter that contains the hash algorithm identifier. In some cases, the algorithm subscript is missing, in which case the algorithm will be determined by context.

The Command Dispatch module will use the hash function when validating certain types of authorizations. Hash functions are also used in support of other operations in the TPM such as PCR Extend.

11.4.4 HMAC Algorithm

The TPM implements the Hash Message Authentication Code (HMAC) algorithm described in ISO/IEC 9797-2.

An HMAC is a form of symmetric signature over some data. It provides assurance that protected data was not modified and that it came from an entity with access to a key value. To have usefulness in protecting data, the key value needs to be a secret or a shared secret.

ISO/IEC 9797-2 defines the HMAC operation as:

$$\mathbf{HMAC}(K, text) = \mathbf{H}((\bar{K} \oplus OPAD) \mid\mid \mathbf{H}((\bar{K} \oplus IPAD) \mid\mid text)) \quad (1)$$

(See ISO/IEC 9797-2 for a description of parameters.)

Performing the HMAC computation requires selection of a hash algorithm. This specification modifies the notation from ISO/IEC 9797-2 to be:

$$\mathbf{HMAC}_{hashAlg}(K, text) \quad (2)$$

If the algorithm subscript is not present, the hash algorithm is implied by the context.

The Command Dispatch module may use the HMAC function to validate an authorization. The HMAC function may be used by the Command Execution module in support of its operations.

11.4.5 Asymmetric Operations

A TPM uses asymmetric algorithms for attestation, identification, and secret sharing. A TPM may support any asymmetric algorithm to which the TCG has assigned an identifier. An asymmetric algorithm identifier will indicate a family of algorithms and methods that are used with that algorithm.

The methods for using an asymmetric algorithm are found in algorithm-specific annexes to this TPM 2.0 Part 1. Currently, the only supported asymmetric algorithms are RSA (described in Annex B) and ECC using prime curves (described in Annex B).

A TPM is required to implement at least one asymmetric algorithm.

 Copyright © TCG 2006-2020

11.4.6 Signature Operations

11.4.6.1 Signing

The TPM may sign using either an asymmetric or a symmetric algorithm. The method of signing depends on the type of the key. For an asymmetric algorithm, the methods of signing are dependent on the algorithm (RSA or ECC). For symmetric signatures, HMAC and SMAC signing schemes are defined. If a key may be used for signing, then it will have the *sign* attribute.

NOTE 1 The signing schemes for RSA are described in B.6 (RSASSA_PKCS1v1_5) and B.7 (RSASSA_PSS). The signing schemes for ECC are described in C.4 (EC Signing).

NOTE 2 Symmetric signing (HMAC and SMAC) may only be performed with unrestricted signing keys.

A key with a sign attribute may also have a restriction on the contents of the message that can be signed with the key. When a key has this restriction, the TPM will not use the key to sign message digests that the TPM did not compute.

Any attestation message produced by a TPM will have a header (TPM_GENERATED_VALUE) to identify the data as being produced within a TPM. If a restricted key is used to sign this data, then a relying party can have assurance that the message data came from a TPM.

To allow a restricted key to sign an externally generated message, the TPM is used to produce the message digest. When the TPM computes the digest, it will validate that the message does not begin with TPM_GENERATED_VALUE. If it does, then the TPM will not produce the special certification (a ticket) that indicates that the digest was produced by the TPM and is safe to sign with a restricted key.

A key designated as a signing key may be used in any command that uses a signing key. For some commands, the signing scheme may be specified in the command. Not all schemes are valid for all keys, and the TPM generates an error if the scheme is not allowed with the indicated key type.

EXAMPLE 1 The RSASSA-PKCS1-v1_5 signing scheme is not valid with an ECC key.

EXAMPLE 2 A key that has the "restricted" attribute may only be used with one signing scheme. If it is limited to be used with RSASSA-PSS, it may not be used with RSASSA-PKCS1-v1_5.

A restricted signing key is required to have a signing scheme specified in the key definition and that is the only signing scheme that is allowed to be used with the key. For an unrestricted key, the key definition may contain a signing scheme selection, or the signing scheme may be determined when the key is used. To defer the signing scheme selection, the key would be created with TPM_ALG_NULL as the signing scheme selection.

11.4.6.2 Signature Verification

TPM2_VerifySignature() validates a signature over a digest. The command takes a handle of a public key, a digest, and a block that contains the signature over the digest.

The TPM validates that the signature scheme is compatible with the selected key. In general, the TPM will be able to validate any signature over a digest that it could have produced.

If the signature is valid, the TPM will produce a ticket.

11.4.6.3 Tickets

A ticket is an HMAC signature that uses a proof value as the HMAC key.

 Copyright © TCG 2006-2020

NOTE Hierarchy proof values are described in detail in14.4.

The TPM uses tickets for two purposes:

- re-signing data. After checking an asymmetric signature, the TPM re-signs the digest using a TPM symmetric key. The TPM can later re-verify a signature without having to load the asymmetric key; and
- expanding state memory. When hashing an external message, the TPM has some state that indicates the message did not start with TPM_GENERATED_VALUE. This state information cannot be retained indefinitely in the TPM. A ticket allows this state to be stored off of the TPM in a way that is easy for the TPM to validate. When a digest is later presented to the TPM to be signed, the ticket is provided allowing the TPM to validate that the digest to be signed is safe to sign.

The proof value used for a ticket will minimally have a number of bits equal to the size of the digest produced by the hash algorithm.

EXAMPLE A proof value of 256 bits is required for a SHA256 ticket.

There are five different ticket types:

1) TPMT_TK_CREATION – this ticket type is produced when an object is created (TPM2_Create() or TPM2_CreatePrimary()). The ticket is used in TPM2_CertifyCreation() so that the TPM can certify that it created a specific object and the environmental parameters (PCR) that were extant when the object was created. This avoids having the digest of the creation data be a permanent part of an object's data structure.
2) TPMT_TK_VERIFIED – this ticket type is produced by TPM2_VerifySignature() and used by TPM2_PolicyAuthorize(). If a signature is signed by an asymmetric key, the signature verification might be time consuming. If the same authorization is going to be used many times (such as an authorization for TPM2_PolicyAuthorize()), there is a performance advantage to having the asymmetric authorization converted so that it uses symmetric cryptography which is usually faster. This ticket is the symmetric equivalent authorization.
3) TPMT_TK_AUTH – this ticket is produced by TPM2_PolicySigned() or TPM2_PolicySecret() and used in TPM2_PolicyTicket(). A policy authorization can be tied to a specific policy session or allowed to be used in any policy. When it can be used in any policy, it has a time at which it expires (which can be some arbitrary time in the future). The long-lived authorization may be given in TPM2_PolicySigned()/TPM2_PolicySecret() and a ticket is produced that is used to verify the authorization parameters (what was authorized) and the time in the future when the authorization expires. This ticket is then processed by TPM2_PolicyTicket() and, until the ticket expires, will have the same effect on the *policyDigest* computation as the original authorization.

NOTE If produced by TPM2_PolicySigned(), the ticket will use the TPM_ST_AUTH_SIGNED structure tag and if produced by TPM2_PolicySecret(), the ticket will use the TPM_ST_AUTH_SECRET structure tag. TPM2_PolicyTicket() will use this tag to indicate which command code to use (TPM_CC_PolicySigned/TPM_CC_PolicySecret) when extending *policyDigest*.

4) TPMT_TK_HASHCHECK – This ticket is used to indicate that a digest of external data is safe to sign using a restricted signing key. A restricted signing key may only sign a digest that was produced by the TPM. If the digest was produced from externally provided data, there needs to be an indication that the data did not start with the same first octets as are used for data that is generated within the TPM. This prevents "forgeries" of attestation data. This ticket is used to provide the evidence that the data used in the digest was checked by the TPM and is safe to sign. Assuming that the external data is "safe", this type of ticket is produced by TPM2_Hash() or TPM2_SequenceComplete() and used by TPM2_Sign().

 Copyright © TCG 2006-2020

5) NULL Ticket – A NULL Ticket is produced when a response has a ticket, but no ticket is produced. An example is TPM2_PolicySecret() with an expiration time of zero. It does not produce a ticket because, since the expiration time was zero, the authorization expires immediately. In this case, the TPM will return a NULL Ticket. A NULL Ticket may also be used as an input parameter when the command requires a ticket, but no ticket data is available.

11.4.7 Symmetric Encryption

The TPM uses symmetric encryption to encrypt some command parameters (typically, authentication information) and to encrypt Protected Objects stored outside it. Cipher Feedback mode (CFB) is the only block cipher mode required by this specification.

Any symmetric block cipher supported by a TPM may be used for parameter encryption. However weak keys are not permitted to be used. Additionally, a TPM should support XOR obfuscation, which is a hash-based stream cipher. XOR obfuscation may be used only for confidential parameter passing.

NOTE XOR allows an application to have confidential and integrity-protected interactions with only one algorithm in common with the TPM (a hash).

When paired with an asymmetric key — as in an ECC decrypting key — a symmetric key is required to have as many bits of security strength as the asymmetric key with which it is paired.

EXAMPLE 1 SP800-57 classifies 2048-bit RSA as providing 112 bits of security. AES with 128- or 256-bit keys provides adequate symmetric security for pairing with a 2048-bit RSA key.

EXAMPLE 2 A prime-modulus ECC key has a security strength that is half the size of the prime modulus. AES with 128- or 256-bit keys is suitable for pairing with a 256-bit ECC key, but AES with 128-bit keys is not recommended for pairing with a 384-bit ECC key.

When a symmetric key is used for data encryption, the encrypted data has an HMAC. This HMAC is checked before the data is decrypted. Verification that the decrypted data is properly associated with the symmetric key is intended to make it more difficult to perform power analysis. To defeat the protections, it would be necessary to defeat two different families of protection rather than one as would exist if the integrity protection were applied to the clear text rather than the cipher text.

11.4.7.1 Block Cipher Modes

The block cipher modes referenced in this specification are defined in ISO/IEC 10116:2006. That specification allows parameterization of most of the modes. In a TPM implementation, the parameters are fixed, as defined in Table 1.

Table 1 — Block Cipher Parameters

Mode	Common Name	Parameter	Comments
CTR	Counter	j = n	size of the plaintext variable
OFB	Output Feedback	j = n	size of the plaintext variable
CBC	Cipher-block Chaining	m = 1	interleave factor
CFB	Cipher-feedback	r = n	size of feedback buffer
		k = n	size of feedback variable
		j = n	size of plaintext variable
ECB	Electronic Code Book	none	
NOTE *n* is the input block size of the cipher.			

 Copyright © TCG 2006-2020

11.4.7.2 Cipher Feedback (CFB) Mode

CFB is used when a symmetric block cipher is chosen as the encryption algorithm associated with a session. When used for parameter encryption, the key and Initialization Vector (IV) are derived from a per-session key so that reuse of the same key and IV is statistically unlikely.

NOTE ISO/IEC 10116 use the term Start Variable instead of Initialization Vector (IV).

CFB is also used for symmetric encryption of the sensitive area of an object when the object is not stored in a Shielded Location. When used in this way, the key and IV are derived from a secret. In some cases, the IV is set to zero.

11.4.7.3 XOR Obfuscation

XOR obfuscation resembles Counter mode (CTR) block encryption, but it uses a KDF as the pseudo-random function instead of a symmetric block cipher.

XOR obfuscation reduces to one (a hash) the number of algorithms that a caller needs in common with the TPM in order to use the TPM with some level of confidentiality and authentication.

This specification's XOR scheme differs from that used in TPM 1.2: it uses a different formulation for input into the hash function.

When this specification calls for use of XOR obfuscation, it uses a function reference. The function prototype is:

$$\mathbf{XOR}(data, hashAlg, key, contextU, contextV) \quad (3)$$

where

data	a variable-sized buffer containing the data to be obfuscated
hashAlg	the hash algorithm to be used in the KDF
key	a variable-sized value containing a secret key
contextU	a variable-sized value used to qualify one of the parties to the operation (often a nonce value)
contextV	a variable-sized value used to qualify one of the parties to the operation (often a nonce value)

The **XOR**() function uses the *hash, key, contextU*, and *contextV* parameters in a call to **KDFa**() to produce a *mask* value:

$$mask \coloneqq \mathbf{KDFa}\ (hashAlg, key, \text{“XOR”}, contextU, contextV, data.size \bullet 8) \quad (4)$$

NOTE The “XOR” value is defined in 4.8.

The octets of *mask* are then XOR'd with the octets of *data.buffer*.

11.4.8 Extend

The Extend operation is used to make incremental updates to a digest value. It is useful for updating PCR, auditing, and constructing policy. Extend uses a hash function to combine new data with an existing digest. Its notation is:

 Copyright © TCG 2006-2020

$$digest_{new} \coloneqq \mathbf{H}_{hashAlg}(digest_{old} \,||\, data_{new}) \quad (5)$$

where

$digest_{new}$	the value of the digest (such as, a PCR) after the Extend operation
$\mathbf{H}_{hashAlg}$	the hash function using a context-specific algorithm (such as, the hash algorithm associated with a specific bank of PCR)
$digest_{old}$	the value of the digest before the Extend operation
$data_{new}$	a variable number of octets of data that are to be hashed with the initial value of $digest_{old}$ to produce Extend results

The Extend operation may also apply to an NV Index that has the TPMA_NV_EXTEND attribute.

11.4.9 Key Generation

Key generation produces two different types of keys. The first, an ordinary key, is produced using the random number generator (RNG) to seed the computation. The result of the computation is a secret key value kept in a Shielded Location.

The second type, a Primary Key, is derived from a seed value, not the RNG directly. The RNG usually generates the seed that is persistently stored on the TPM. Generation of a Primary Key from a seed is based on use of an approved key derivation function (KDF). The KDF from SP800-108 is widely used in this specification.

This specification places no upper limit on the time allowed to generate a key. Platform-specific specifications may limit the time for generating various key types.

Depending on the application, the TPM may generate a key by

- using bits from the RNG, or
- deriving the key from another secret value.

There are many ways to generate keys; these methods are described in detail in each clause where generation of a key is required.

11.4.10 Key Derivation Function

11.4.10.1 Introduction

The TPM uses a hash-based function to generate keys for multiple purposes. This specification uses two different schemes: one for ECDH and one for all other uses of a KDF.

The ECDH KDF is from SP800-56A. The Counter mode KDF, from SP800-108, uses HMAC as the pseudo-random function (PRF). It is referred to in the specification as **KDFa**().

11.4.10.2 KDFa()

With the exception of ECDH, **KDFa**() is used in all cases where a KDF is required. **KDFa**() uses Counter mode from SP800-108, with HMAC as the PRF.

As defined in SP800-108, the inner loop for building the key stream is:

$$K(i) \coloneqq \mathbf{HMAC}\,(K_I, [i]_2 \,||\, Label \,||\, 00_{16} \,||\, Context \,||\, [L]_2) \tag{6}$$

where

$K(i)$	the ith iteration of the KDF inner loop
HMAC()	the HMAC algorithm using an approved hash algorithm
K_I	the secret key material
$[i]_2$	a 32-bit counter that starts at 1 and increments on each iteration
$Label$	a octet stream indicating the use of the key produced by this KDF
00_{16}	Added only if *Label* is not present or if the last octet of *Label* is not zero.
$Context$	a binary string containing information relating to the derived keying material
$[L]_2$	a 32-bit value indicating the number of bits to be returned from the KDF

NOTE 1 Equation (6) is not **KDFa**(). **KDFa**() is the function call defined below.

As shown in equation (6), there is an octet of zero that separates *Label* from *Context*. In SP800-108, *Label* is a sequence of octets that may or may not have a final octet that is zero. If *Label* is not present, a zero octet is added. If *Label* is present and the last octet is not zero, a zero octet is added.

After each iteration, the HMAC digest data is concatenated to the previously produced value until the size of the concatenated string is at least as large as the requested value. The string is then truncated to the desired size (which causes the loss of some of the most recently added bits), and the value is returned.

When this specification calls for use of this KDF, it uses a function reference to **KDFa**(). The function prototype is:

$$\mathbf{KDFa}\,(hashAlg, key, label, contextU, contextV, bits) \tag{7}$$

where

hashAlg	a TPM_ALG_ID to be used in the HMAC in the KDF
key	a variable-sized value used as K_I
label	a variable-sized octet stream used as Label
contextU	a variable-sized value concatenated with *contextV* to create the *Context* parameter used in equation (6) above
contextV	a variable-sized value concatenated to *contextU* to create the *Context* parameter used in equation (6) above
bits	a 32-bit value used as $[L]_2$; and is the number of bits returned by the function

The values of *contextU* and *contextV* are passed as sized buffers and only the buffer data is used to construct the *Context* parameter used in equation (6) above. The size fields of *contextU* and *contextV* are not included in the computation. That is:

$$Context \coloneqq contextU.buffer \,||\, contextV.buffer \tag{8}$$

 Copyright © TCG 2006-2020

The 32-bit value of $bits$ is in TPM canonical form, with the least significant bits of the value in the highest numbered octet.

The implied return from this function is a sequence of octets with a length equal to (*bits* + 7) / 8. If *bits* is not an even multiple of 8, then the returned value occupies the least significant bits of the returned octet array, and the additional, high-order bits in the 0th octet are CLEAR. **The unused bits of the most significant octet (MSO) are masked off and not shifted.**

EXAMPLE If **KDFa**() were used to produce a 521-bit ECC private key, the returned value would occupy 66 octets, with the upper 7 bits of the octet at offset zero set to 0.

11.4.10.3 KDFe for ECDH

Producing a symmetric encryption key for an ECC-protected object uses “One-Pass Diffie-Hellman, C(1, 1, ECC CDH)” from SP800-56A, 6.2.2.2. The KDF used is the “Concatenation Key Derivation Function (Approved Alternative 1)”. The inner loop of that KDF uses:

$$digest_i \coloneqq \mathbf{H}(counter \mid\mid Z \mid\mid OtherInfo) \tag{9}$$

where

$digest_i$	the digest generated on the ith iteration of the loop (i starts at 1)
$\mathbf{H}()$	an approved hash function
$counter$	a 32-bit counter that is initialized to 1 and incremented on each iteration
Z	the X coordinate of the product of a public ECC key and a different private ECC key
$OtherInfo$	a collection of qualifying data for the KDF defined below

The 32-bit $counter$ value is included in TPM canonical form, with the least-significant bit of the counter in the highest numbered octet.

After each iteration, $digest_i$ is concatenated to the previously produced digests (MSO of $digest_i$ follows the LSO of $digest_{i-1}$). The number of iterations is determined by the number of bits to be produced and the size of the digest produced by the hash function. In the returned octet string, the MSO of the returned value is the MSO of $digest_1$.

In SP800-56A, *OtherInfo* is specified as:

$$OtherInfo \coloneqq AlgorithmID \mid\mid PartyUInfo \mid\mid PartyVInfo \;\{\mid\mid SuppPubInfo\}\; \{\mid\mid SuppPrivInfo\} \tag{10}$$

where

$AlgorithmID$	a bit string that indicates how the derived keying material will be parsed and for which algorithm(s)
$PartyUInfo$	public information contributed by party U (the initiator)
$PartyVInfo$	public information contributed by party V (the responder)
$SuppPubInfo$	public information known to both U and V (optional)
$SuppPrivInfo$	private (secret) information known to both U and V (optional)

This specification requires that $OtherInfo$ be constructed as:

 Copyright © TCG 2006-2020

$$OtherInfo \coloneqq Use \,||\, PartyUInfo.buffer \,||\, PartyVInfo.buffer \tag{11}$$

where

Use	a null-terminated string indicating the use of the key (e.g., "DUPLICATE", "IDENTITY", "SECRET", etc.) (see clause 4 for the definition of these values). This field satisfies the requirements of SP800-56A since the parsing of keying material is determined by the use.
PartyUInfo.buffer	the x-coordinate of the public point of an ephemeral key
PartyVInfo.buffer	the x-coordinate of the public point of a static TPM key

The x-coordinates of the public points are *sized buffers* (that is, integers indicating the size in octets of the buffer that follows). The buffer data is used in the KDF, but the size field is not.

When this specification calls for use of this KDF, it uses a function reference to **KDFe**(). The function prototype is:

$$\mathbf{KDFe}(hashAlg, Z, Use, PartyUInfo, PartyVInfo, bits) \tag{12}$$

where

hashAlg	the hash algorithm to be used as **H**() in equation (9) above
Z	the product of a public point and a private x-coordinate
Use	a null-terminated string indicating the use of the key (e.g., "DUPLICATE", "IDENTITY", "SECRET", etc.) (see clause 4 for the definition of these values).
PartyUInfo	the x-coordinate of the public point of an ephemeral key
PartyVInfo	the x-coordinate of the public point of a static TPM key
bits	a 32-bit value indicating the number of bits to be returned

The implied return from this function is an octet string containing $bits/8$ octets. If *bits* is not an even multiple of 8, the return value is the least-significant bits of the return value, and the additional high-order bits in the 0th octet are CLEAR. The unused bits of the MSO are masked off and not shifted.

NOTE The function prototype in (12) is not a C-language prototype but, rather, a prototype to illustrate the parameters of the KDF for specific uses. The C-language prototype will include an extra parameter that will be the buffer to receive the key material generated by the KDF.

11.4.10.4 Rejection of weak keys

Some algorithms have known weak keys. If such a key is generated, it must be discarded, and a new key generated by starting over with another iteration of the KDF. In the case of DES, there are 64 known weak or semi-weak keys. None of them are allowed. In the case of AES, at least one bit in the upper half of the key must be set. Again, if this is not true, the key must be discarded, and a new key generated by starting over with another iteration of the KDF.

11.4.11 Random Number Generator (RNG) Module

11.4.11.1 Source of Randomness

The RNG is the source of randomness in the TPM. The TPM uses random values for nonces, in key generation, and for randomness in signatures.

The RNG is a Protected Capability with no access control. It nominally consists of

- an entropy source and collector,
- a state register, and
- a mixing function (typically, an approved hash function).

The entropy collector collects entropy from entropy sources and removes bias. The collected entropy is then used to update the state register providing input to the mixing function to produce the random numbers.

The mixing function may be implemented with a pseudo-random number generator (a PRNG). A PRNG may produce numbers that are apparently random from a non-random input (such as, a counter). Combining an approved PRNG with an input that has considerably more entropy than a counter yields an RNG with properties no worse than the underlying PRNG and possibly much better.

The RNG should meet the certification requirements of the intended market.

The TPM should provide sufficient randomness for each use by an internal function. When accessed by an external call, it should be able to provide 32 octets of randomness. Larger requests may fail if insufficient randomness is available.

Each RNG access produces a new value regardless of the data's use. There is no distinction between accesses for internal versus external purposes.

11.4.11.2 Entropy Source and Collector

A TPM should have at least one internal source of entropy, and possibly more. These sources could include noise, clock variations, air movement, and other types of events.

As noted, the entropy collector is the process that collects the entropy from various sources and removes bias.

EXAMPLE If the entropy source has a bias of creating 60 percent 1s and only 40 percent 0s, then the collector design corrects the bias before sending the information to the state register.

The entropy source and collector should provide entropy to the state register in a manner that is not visible to an outside process or other TPM capability.

The entropy collector should regularly update the state register with additional, unbiased entropy.

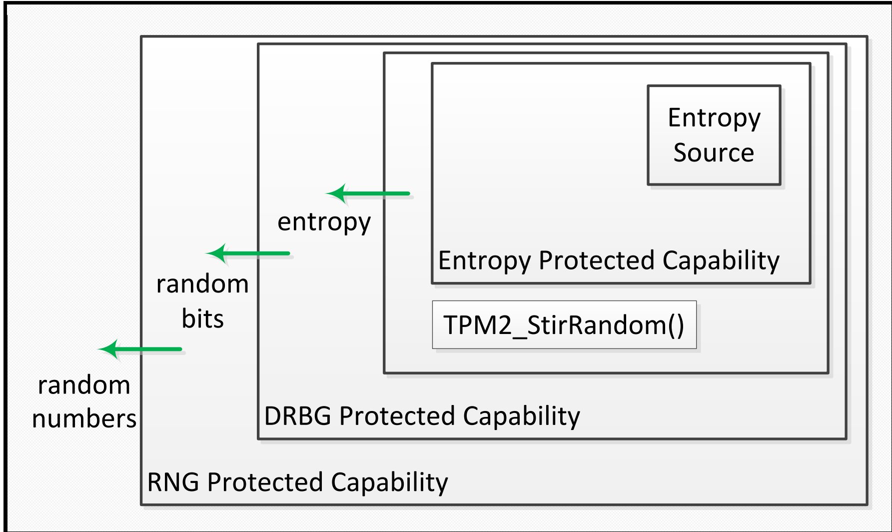


Figure 4 — Random Number Generation

Any Protected Capability that requires an unpredictable number obtains it from a Random Number Generator (RNG) Protected Capability in the same TPM. The RNG Protected Capability assembles random bits from a Deterministic Random Bit Generator (DRBG) Protected Capability in the same TPM. The DRBG Protected Capability obtains entropy from the entropy Protected Capability in the same TPM and the TPM2_StirRandom() Protected Capability can be used to add additional information. The entropy Protected Capability obtains entropy from an entropy source in the same TPM.

NOTE 1 The "additional information" added by TPM2_StirRandom() could be entropy gathered from other sources but the TPM has no way of determining if the value has any entropy or not. As a consequence, it is just deemed to be "additional information."

NOTE 2 The DRBG Protected Capability of a non-FIPS TPM consists of a DRBG mechanism that should comply with NIST Recommendation SP800-90 A, revised March 2012; except it does not comply with its Clause 11.

NOTE 3 The DRBG Protected Capability of a FIPS TPM consists of a DRBG mechanism that complies with NIST Recommendation SP800-90 A, revised March 2012.

The DRBG mechanism security should be at least as strong as the security strength of the strongest cryptographic algorithm implemented in the TPM.

The DRBG Protected Capability should be reseeded using entropy from the entropy Protected Capability when:

- a flag is SET indicating that reseeding is required;
- TPM2_StirRandom() is executed;
- after the TPM has failed a self-test; or
- before the SPS is replaced.

It may be reseeded at other times, as well.

NOTE 4 Each TPM may be seeded during TPM manufacture, via a manufacturer-specific method, using a personalization string for the DRBG that should be specific to the manufacturer and the type of TPM, plus a manufacturer-provided nonce that is specific to the individual TPM.

11.4.11.3 Nonce Creation

The RNG module provides the bits used in any TPM-generated nonce.

11.4.12 Algorithms

11.4.12.1 Algorithm Identifiers

The structures and commands in this specification are constructed with minimal reliance on algorithm defaults.

In most cases, an algorithm identifier identifies a family of algorithms followed by qualifiers. This differs from the TPM 1.2 version of the specification, which often included the key size in the algorithm identifier (TPM_ALG_AES128). This specification only uses the TPM 1.2 form of algorithm identifiers for hash algorithms.

Since this specification depends on being able to discern the hash output size from the algorithm ID, its hash algorithm identifiers imply a digest size.

EXAMPLE 1 Some of the hash algorithm identifiers are TPM_ALG_SHA256, TPM_ALG_SHA384, and TPM_ALG_SM3_256.

Algorithm identifiers for symmetric and asymmetric encryption identify the family, such as RSA, ECC, AES, etc. For these algorithms, supplementary information is required to define parameters.

EXAMPLE 2 Some family algorithm identifiers are TPM_ALG_ECC, TPM_ALG_RSA, TPM_ALG_SM4, and TPM_ALG_AES.

11.4.12.2 Algorithm Support

This specification does not require implementation of any specific set of algorithms. When determining algorithms or algorithm sets supported, implementers should carefully consider factors such as use cases, strength of function, interoperability, backward compatibility, algorithm diversity, etc. TCG recommends using TCG platform-specific specifications that reflect industry best practices.

NOTE 1 It is anticipated that support for TPM 1.2 compatibility will be retained unless support for the 1.2 algorithms (RSA 2048 and SHA1) would prevent that TPM from being sold.

TCG will specify sets of algorithms to be incorporated by various platform-specific specifications. Each set includes a minimum of one hash algorithm, one symmetric encryption algorithm with approved parameters, and one asymmetric encryption/signing algorithm with approved parameters. Without a complete set of algorithms, the TPM would be unable to support all necessary functions.

A TPM may support algorithms in addition to the required sets. These do not need to be part of any set. For example, the TPM may include an additional hash algorithm without including an additional asymmetric or symmetric algorithm.

It is possible, and very likely given the multitude of algorithms supported by the TPM, that key-size support will differ between TPM implementations. In addition, keys created by outside software may greatly increase the number of key sizes that are possible to load.

A TPM will not create or load an object that uses an algorithm that is not supported by the TPM. When creating an object, the TPM checks the template for the object being created and when loading an object, the TPM checks the public area of the object. In both cases, the TPM validates that it supports all of the indicated algorithms, parameters, and key sizes.

 Copyright © TCG 2006-2020

The strength of at least one algorithm set supported by a TPM should be at least 112 bits. Other algorithms and algorithm sets may be supported in any combination.

NOTE 2 A set's strength is normally determined by the number of bits in a key of the symmetric algorithm. An exception is Suite B, Top Secret, where the strength is considered to be 192 bits even though the symmetric algorithm has 256-bit keys.

If a TPM supports RSA, it should support a key size of 2048 bits or larger. Support for smaller key sizes is allowed but discouraged.

NOTE 3 Support for smaller keys is allowed so that legacy keys may continue to be supported. Use of key-sizes less than 1024 bits is strongly discouraged.

A platform-specific specification may mandate support for algorithms or algorithm sets. It may select only those algorithms for which the TCG has assigned algorithm identifiers.

A TPM may only implement algorithms that have a TCG-assigned algorithm ID.

11.5 Authorization Subsystem

The Authorization Subsystem is called by the Command Dispatch module at the beginning and end of command execution. Before the command may be executed, the Authorization Subsystem checks that proper authorization for use of each of the Shielded Locations has been provided.

Some commands access Shielded Locations that require no authorizations; access to some locations may require a single-factor authorization; and access to other Shielded Locations may require use of an authorization policy of arbitrary complexity.

The only cryptographic functions required by the Authorization Subsystem are hash and HMAC. An asymmetric algorithm may be required if TPM2_PolicySigned() is implemented.

The details of the different methods of authorization are provided in Clause 19.

11.6 Random Access Memory

11.6.1 Introduction

Random access memory (RAM) holds TPM transient data. Data in TPM RAM is allowed, but not required, to be lost when TPM power is removed. Because the values in TPM RAM may be lost, in this specification they are referred to as being volatile, even if the data loss is implementation-dependent.

When the specification refers to a value that has both volatile and non-volatile copies, they may be kept in a single location as long as that location has the properties of allowing random access and having unlimited endurance.

Not all values in TPM RAM are in Shielded Locations. A portion of TPM RAM contains the I/O buffer with properties that are described in 11.3.

11.6.2 Platform Configuration Registers (PCR)

PCR are Shielded Locations used to validate the contents of a log of measurements. The nominal behavior of a trusted platform is to maintain, in a log, a record of the events that affect the security state of the platform, at least through the boot process while it is establishing the TCB. When additions are made to the log, the TPM receives a copy of the log entry or the digest of data described by the log. The

data sent to the TPM is included in an accumulative hash in a PCR. The TPM may then provide an attestation of the value in the PCR, which, in turn, verifies the contents of the log.

It is possible for a single PCR to record all log entries. However, this would make it difficult to evaluate the different stages of platform evolution as it boots into the operating system. Normally, multiple PCR are provided in a TPM to allow simplification of the evaluation.

EXAMPLE 1 A TPM intended for a PC could have a PCR dedicated to recording measurements of the BIOS, a PCR dedicated to the boot ROM on add-in cards, and a PCR dedicated to the OS loader. The platform-specific specifications determine the number of PCR and their attributes in a TPM.

PCR may also be used to gate access to an object. If selected PCR do not have the required values, the TPM will not allow use of the object.

A TPM may maintain multiple banks of PCR. A PCR bank is a collection of PCR that are Extended with the same hash algorithm. PCR banks are identified by the hash algorithm used to Extend the PCR in that bank.

Multiple banks may handle situations where one hash algorithm is required for legacy or compatibility with one set of applications, while a different hash algorithm is required to meet the security needs of another application. Within a bank, all PCR updates use the same hash algorithm. Not all banks need to have the same number of PCR, but the attributes of all PCR with the same Index, other than hash algorithm, are the same in all banks.

EXAMPLE 2 If PCR[0] has an attribute that allows it to be reset by TPM2_PCR_Reset(), then that attribute applies to PCR[0] in all banks.

NOTE 1 Since banks may have different numbers of PCR, a PCR Index value may not be valid for all banks. The allocation of PCR may also be changed by TPM2_PCR_Allocate() using Platform Authorization. Changing the PCR allocation does not change the attributes of the PCR.

The contents of a PCR may be modified or reported. The two ways to modify a PCR are to reset it or Extend it. Reporting on a PCR may be accomplished through simple reading, inclusion in an attestation, or inclusion in a policy.

Although listed in this clause, PCR need not be maintained in RAM. They may be kept in non-volatile memory. If kept in non-volatile memory, consideration must be made for the possible impact on TPM performance during the critical boot phase, when many measurements are recorded.

A TPM is required to implement a PCR bank for each supported algorithm. However, a PCR bank may be defined such that it contains no PCR.

NOTE 2 The requirement that a PCR bank be implemented for each hash algorithm allows the unmarshaling to be based on the implemented algorithms rather than the implemented PCR.

The TPM may support Resume PCR that retain their state across a TPM Resume sequence but are set to their default initial value on TPM Reset or TPM Restart.

11.6.3 Object Store

TPM RAM holds keys and data that are loaded into the TPM from external memory. In most cases, an object may not be used or modified unless it was first loaded into TPM RAM with one of the object load commands: (TPM2_Load(), TPM2_CreatePrimary(), TPM2_LoadExternal(), or TPM2_ContextLoad()).

NOTE TPM2_Create() does not automatically load the object. After creation, the object needs to be explicitly loaded with TPM2_Load(), to load both the public and private portions, or with TPM2_LoadExternal() to load just the public portion.

 Copyright © TCG 2006-2020

The structure used for keys may be generalized for use on data objects if the access properties used for keys are suitable for access to these objects.

EXAMPLE A data blob may be defined so that access requires that some set of PCR has defined values, or an authorization value may be needed for access. Such a data blob, called a Sealed Data Object, is managed in the same way that a key is managed. That is, the Sealed Data Object should be loaded before being accessed, and the loaded blob may be context saved.

The TPM operates on other structures that are passed as parameters in specific commands. These structures are transient and are not stored in the TPM as identifiable entities after the command has completed.

Items loaded in the TPM are given handles to let them be referenced in subsequent commands.

11.6.4 Session Store

The TPM uses sessions to control a sequence of operations. A session may audit actions, provide authorizations for actions, or encrypt parameters passed in commands.

A session may be created as needed using one of the session creation commands. The session is assigned a handle at that time.

A TPM may be designed so that the RAM used for sessions is from a memory pool shared with the object store. It may also be designed so that the session store and object store are separated and dedicated.

11.6.5 Size Requirements

Random access memory (RAM) should be large enough to handle the transient state, sessions, and objects needed for completion of any implemented command. The minimums for the worst-case command in this specification are:

- two loaded entities (two keys, a key and a Sealed Data Object, or a hash/HMAC sequence and a key);
- three authorization sessions;
- an input buffer able to accommodate the largest command or an output buffer required for the largest possible response;

NOTE The largest command or response depends on the algorithms supported by the implementation.

- any vendor-defined state required for operation; and
- all defined PCR.

11.7 Non-Volatile (NV) Memory

The NV memory module stores persistent state associated with the TPM. Some NV memory is available for allocation and use by the platform and entities authorized by the TPM Owner.

TPM NV memory contains Shielded Locations and Shielded Location can only be accessed with Protected Capabilities.

If the specification is not explicit about storage of a parameter, that parameter may be in either RAM or NV, according to vendor preference.

If the NV memory of the TPM is subject to wear, then the TPM should detect whether the data being written to an NV memory location is the same as that currently stored and not perform the NV write if they are the same.

The OS or the platform may define a special NV data structure (an NV Index) in order to store persistent data values. NV memory may also be used persistently to store a loaded object. When a persistent object is referenced in a TPM command, the TPM may move that object into an object slot so it may be accessed more efficiently. The TRM needs to ensure that sufficient object memory RAM is available to allow this movement.

NOTE The movement occurs transparently.

A TPM capability indicates if the TPM is using Transient Object resources when a command references a persistent object. If so, the TRM needs to ensure that a Transient Object slot is available for each persistent object so referenced.

11.8 Power Detection Module

This module manages TPM power states in conjunction with platform power states.

All platform-specific TCG specifications that define the binding of the TPM to the platform should include a requirement that the TPM be notified of all power state changes.

The TPM supports only the ON and OFF power states. Any system power transition requiring the RTM to be reset also causes the TPM to be reset (_TPM_Init). Any system power transition that causes the TPM to be reset will also cause the RTM to be reset.

NOTE In most cases, the RTM will be a host CPU.

 Copyright © TCG 2006-2020

12 TPM Operational States

12.1 Introduction

This clause describes TPM operational states and state transitions.

12.2 Basic TPM Operational States

12.2.1 Power-off State

A hardware TPM is in the Power-off state when reset is being asserted or when no power is applied to the TPM. The TPM may internally generate reset by detecting low power or reset may be provided by an external source.

It is possible to transition to the Power-off state from any other state because power can be lost at any time.

NOTE Uncontrolled transitions to this state are not shown in diagrams/descriptions because they would add unnecessary clutter and provide no additional understanding.

12.2.2 Initialization State

The TPM is placed in its initialization state when it receives the _TPM_Init indication. _TPM_Init is provided in a platform-specific manner. For a hardware TPM, the _TPM_Init is normally signaled by the de-assertion of the TPM's reset signal. It may also be signaled by an interface protocol or setting. For a software implementation, _TPM_Init may be a dedicated procedure call.

Regardless of how it is generated, _TPM_Init should coincide with a reset of the Roots of Trust for Measurement for which the TPM is the Root of Trust for Reporting. For example, if the TPM is a component on the PC's motherboard, _TPM_Init should coincide with a reset of the processor and chipset. After _TPM_Init is indicated, the RTM should begin executing the Core Root of Trust for Measurement. It should not be possible to reset the TPM without resetting the RTM. It should not be possible to reset the RTM without resetting the TPM.

While in the Initialization state, the TPM performs basic initialization functions in preparation for accepting commands on the TPM interface. These functions are implementation dependent but, minimally, the TPM should perform validation of the TPM firmware necessary to execute the expected command. If the TPM is in Field Upgrade mode (FUM), the expected command is TPM2_FieldUpgradeData(). If the TPM is not in FUM, the expected command is TPM2_Startup().

After completing the initializations, the TPM waits for the next command and, if the command is not the expected first command, the TPM will return an error indicative of the mode. If the TPM returns an error, it will continue to wait for the expected first command.

NOTE 1 If the TPM is not in FUM, it returns TPM_RC_INITIALIZE. If the TPM is in FUM, it returns TPM_RC_UPGRADE.

NOTE 2 If TPM2_Startup()/TPM2_FieldUpgrateData() is not the first command to the TPM, it indicates failure of the system to properly enter the CRTM, and the reliability of TPM measurements may not be assured. While it is possible to define a special failure mode that prohibits just PCR-related operations, it is expected to be infrequent enough not to warrant such a mode and, as shown in Figure 5, the TPM does not enter Failure Mode, if the first command is not TPM2_Startup().

When the TPM receives TPM2_Startup(), it becomes operational and is able to process other commands.

 Copyright © TCG 2006-2020

NOTE 3 For compliance with other standards, such as FIPS 140, it is necessary for the TPM to validate the firmware associated with a command's execution before that command is executed. This includes the code associated with TPM2_Startup() and TPM2_FieldUpgadeData(). This validation may require use of a digital signature or message authentication code.

Occasionally, some TPM state may need to be retained over a power transition. This might occur if the platform is entering the Suspend state, where the preponderance of system state is retained. To allow the TPM to reflect this condition, system software may issue TPM2_Shutdown(TPM_SU_STATE) to the TPM.

TPM2_Shutdown() initiates an orderly shutdown of the TPM. The command's *startupType* parameter indicates the type of startup that is anticipated to follow and the type of data to be saved. For TPM2_Shutdown(TPM_SU_CLEAR), the amount of data saved to NV memory is relatively small, with considerably more information retained when TPM_SU_STATE is indicated.

12.2.3 Startup State

12.2.3.1 TPM2_Startup()

TPM2_Startup() transitions the TPM from the Initialization state to an Operational state. The command includes information from the platform to inform the TPM of the platform's operating state. TPM2_Startup() has two options: TPM_SU_CLEAR and TPM_SU_STATE. The operating state of a TPM after TPM2_Startup() is dependent on how the TPM was shut down and the selected startup option.

12.2.3.2 Startup Types

The following terms are used to refer to the different startup and shutdown operations:

- Startup(CLEAR) means TPM2_Startup(*startupType* == TPM_SU_CLEAR);
- Startup(STATE) means TPM2_Startup(*startupType* == TPM_SU_STATE);
- Shutdown(STATE) means TPM2_Shutdown(*startupType* == TPM_SU_STATE); and
- Shutdown(CLEAR) means TPM2_Shutdown(*startupType* == TPM_SU_CLEAR).

The combinations of Shutdown() and Startup() provide three unique methods of preparing the TPM for operation:

1) **TPM Reset** is a Startup(CLEAR) that follows a Shutdown(CLEAR), or a Startup(CLEAR) for which there was no preceding Shutdown() (that is, a disorderly shutdown). A TPM Reset is roughly analogous to a reboot of a platform. As with a reboot, most values are placed in a default initial state, but persistent values are retained. Any value that is not required by this specification to be kept in NV memory is reinitialized. In some cases, this means that values are cleared, in others it means that new random values are selected.
2) **TPM Restart** is a Startup(CLEAR) that follows a Shutdown(STATE). This indicates a system that is restoring the OS from non-volatile storage, sometimes called "hibernation". For a TPM Restart, the TPM restores values saved by the preceding Shutdown(STATE) except that all the PCR are set to their default initial state. This allows the TPM to record the boot sequence to ensure that the TCB is properly instantiated while allowing continued function of the restored OS.
3) **TPM Resume** is a Startup(STATE) that follows a Shutdown(STATE). This indicates a system that is restarting the OS from RAM memory, sometimes called "sleep." For sleep, the expectation is that the CRTM will perform the minimal actions required to make the system functional and then "return" to the running OS rather than rebooting it. TPM Resume restores all of the state that was saved by Shutdown(STATE), including those PCR that are designated as being preserved by Startup(STATE). PCR not designated as being preserved, are reset to their default initial state.

 Copyright © TCG 2006-2020

NOTE 1 The PCR are designated in a platform-specific specification.

If the TPM receives Startup(STATE) that was not preceded by Shutdown(STATE), then there is no state to restore and the TPM will return TPM_RC_VALUE. The CRTM is expected to take corrective action to prevent malicious software from manipulating the PCR values such that they would misrepresent the state of the platform. The CRTM would abort the Startup(State) and restart with Startup(CLEAR).

NOTE 2 The startup behavior defined by this specification is different than TPM 1.2 with respect to Startup(STATE). A TPM 1.2 device will enter Failure Mode if no state is available when the TPM receives Startup(STATE). This is not the case in this specification. It is up to the CRTM to take corrective action if it the TPM returns TPM_RC_VALUE in response to Startup(STATE).

The TPM is required to validate the integrity of any NV values before those values are used before that state is used. This includes the state saved by TPM2_Shutdown(STATE)(see 12.2.4). When the TPM determines that some NV value required for proper TPM operation is not valid, the TPM will enter Failure Mode.

It is not specified when the validation of state specific to TPM Resume is to be checked. This gives implementation options that may be specified by a platform-specific specification or determined by the vendor.

The startup sequences are illustrated in Figure 5.

 Copyright © TCG 2006-2020

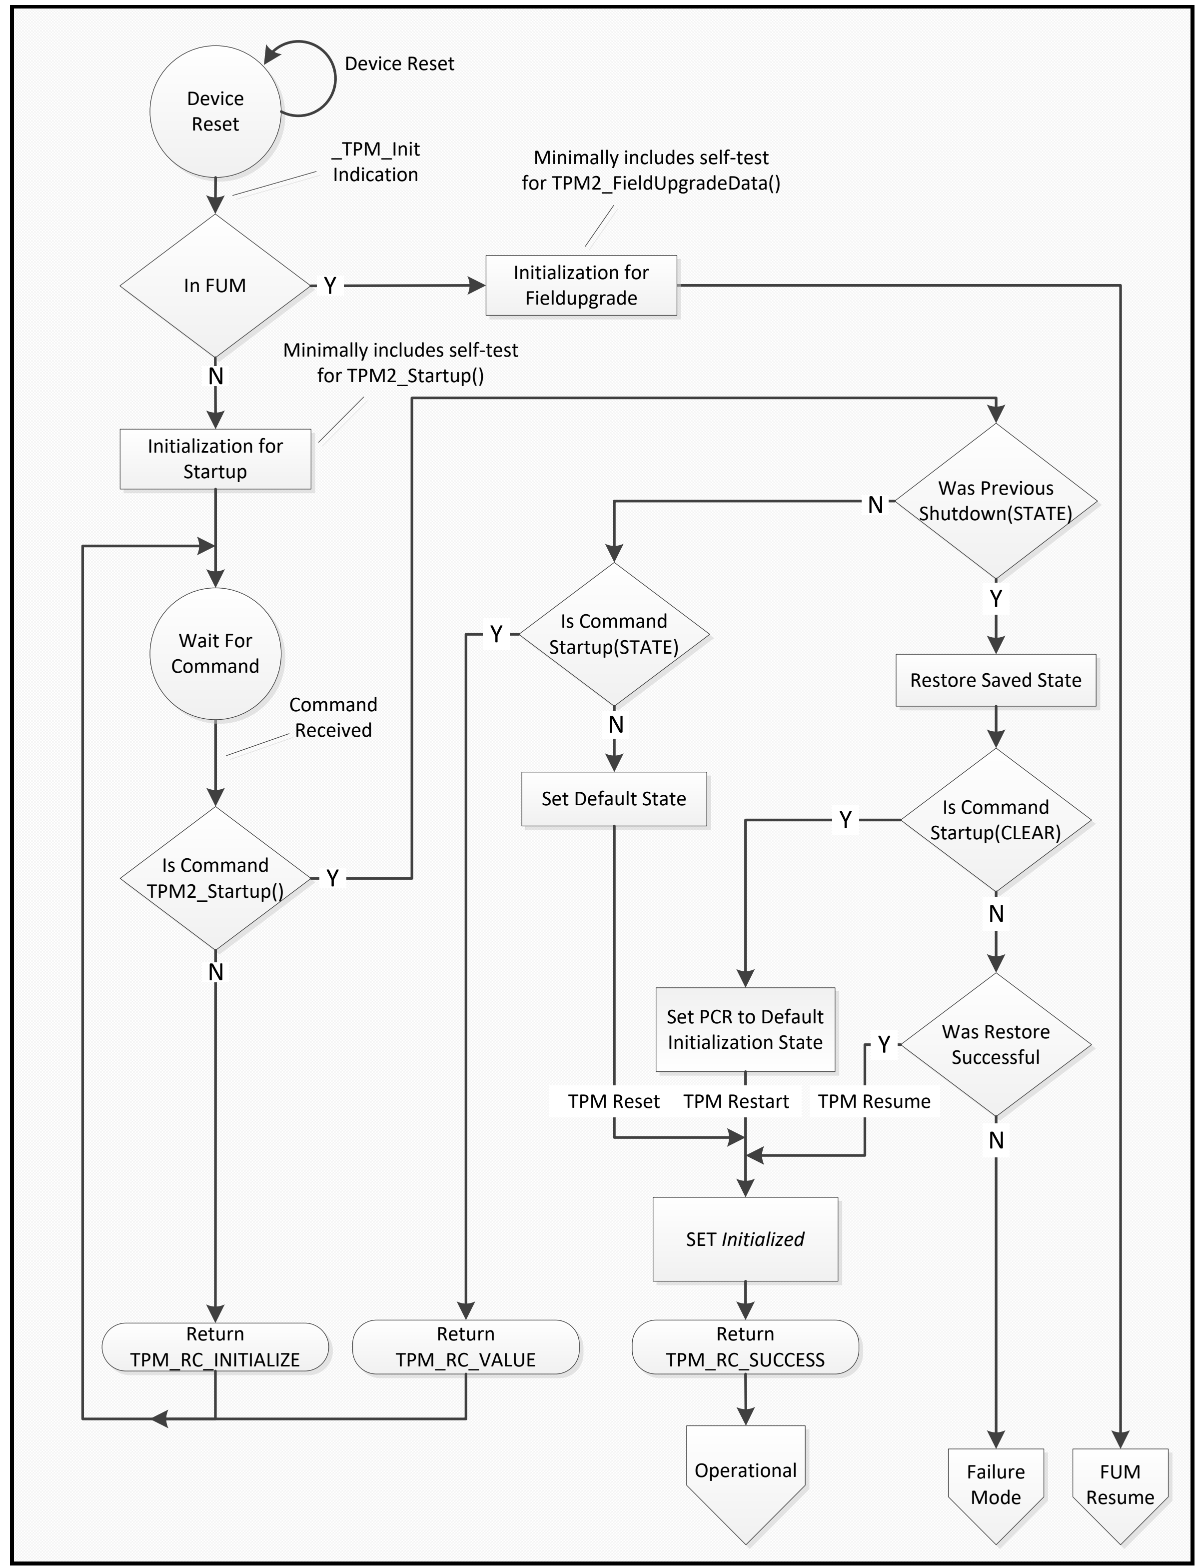

Figure 5 — TPM Startup Sequences

12.2.4 Shutdown State

TPM2_Shutdown() is used to prepare the TPM for loss of power. As with TPM2_Startup(), TPM2_Shutdown() has two options: TPM_SU_CLEAR and TPM_SU_STATE.

 Copyright © TCG 2006-2020

TPM2_Shutdown(TPM_SU_STATE) preserves the majority of the TPM operational state so that it may be restored on a subsequent TPM2_Startup(). TPM2_Shutdown(TPM_SU_CLEAR) preserves a minimal amount of state, mostly to ensure continuity of the TPM timing functions.

NOTE The timing functions are described in Clause 36.

The TPM preserves state data in NV memory. Data is copied from RAM into NV memory so that it is not lost when power is removed from the TPM. The amount of data copied to NV memory is largely implementation-dependent, but the specification indicates the state data that is required to be preserved. This state data is recovered in a subsequent TPM2_Startup(). The type of startup determines what parts of the saved state data is restored and what is discarded.

A shutdown is "orderly" if the TPM receives TPM2_Shutdown() before power is lost and if the state is not subsequently modified by a TPM command before the next _TPM_Init.

These commands will invalidate saved TPM state:

NOTE This is not an inclusive list:

- TPM2_Clear(), TPM2_ChangeEPS(), TPM2_ChangePPS() – these commands invalidate saved contexts in the hierarchy. TPM2_Clear() invalidates preserved contexts in both the storage and endorsement hierarchies.
- TPM2_ContextSave() – context variables are modified by context save. Saving a session context changes the session context ID and its tracking state (saved or in memory). Saving an object context changes the object context ID.
- TPM2_ContextLoad() for a session – the context ID and tracking state (in TPM or context saved) for each active session should be retained across a TPM Restart or TPM Resume sequence. Saving or loading a session context changes the context ID or its tracking state. Saving or loading an object context need not invalidate a preserved context.
- Any command that modifies a PCR – regardless of the implementation, any change to a Resume PCR will invalidate the saved state. If the TPM implements TPM2_PolicyPCR() and uses a PCR generation counter, any PCR modification will change this counter value.

EXAMPLE If a Shutdown(STATE) occurs but, prior to Startup(STATE), a TPM2_PCR_Event() is executed selecting a Resume PCR, then the preserved state is no longer valid, and Startup(STATE) is not valid until another Shutdown(STATE) occurs.

- Any command that modifies *Clock* or returns the value of *Clock*.

A TPM implementation may invalidate a preserved context on any command except TPM2_GetCapability().

12.2.5 Startup Alternatives

The description of the startup process above was given in terms of a command interface. In some systems, the TPM code is run in a special processor mode that provides the required isolation between the TPM state and any other program state. For these implementations, TPM2_Startup() may not be a command that is actually implemented. That is, the platform initialization may boot, validate the TPM code, and place the TPM in a state that is functionally equivalent to having run TPM2_Startup() on a discrete TPM component.

12.3 Self-Test Modes

If a command requires use of an untested algorithm or functional module, the TPM performs the test and then completes the command actions. When performing a self-test on demand, the TPM should test only those algorithms needed to complete the command (see Figure 6).

NOTE 1 It is preferable for the TPM to perform self-tests on untested algorithms and functional blocks as a background task to increase the likelihood that algorithms are tested before they are needed.

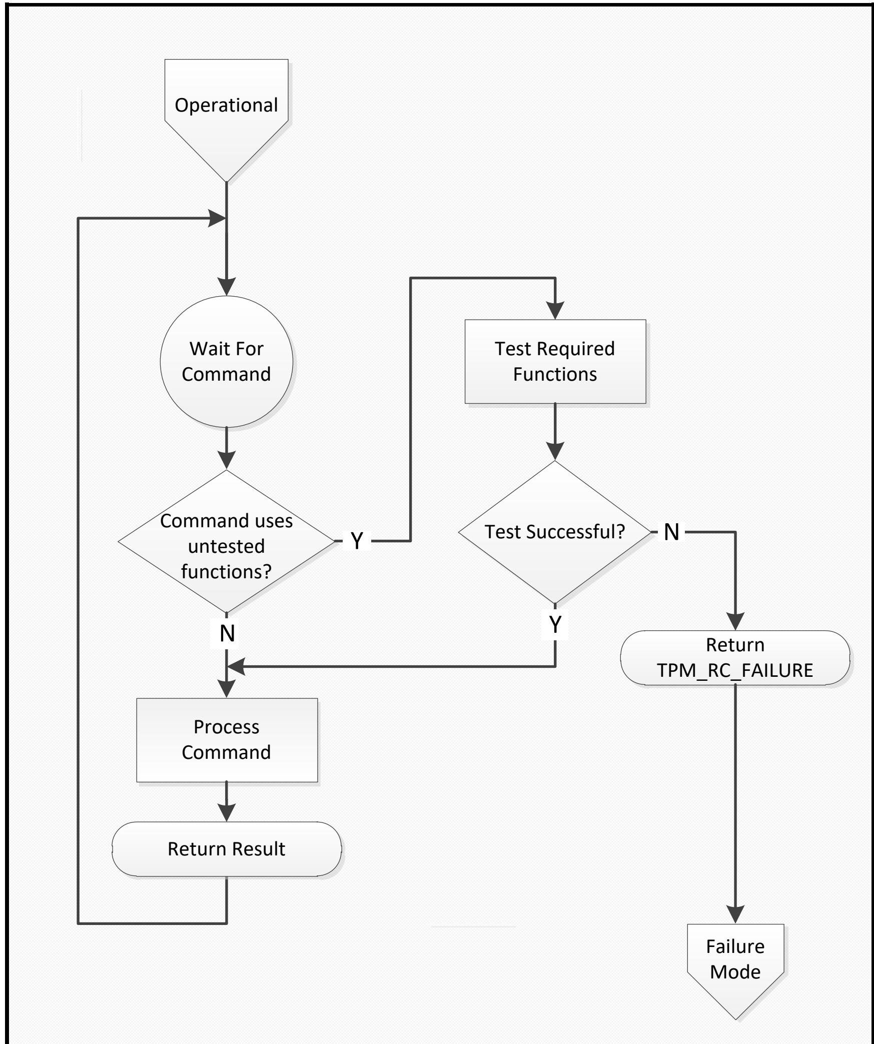

Figure 6 — On-Demand Self-Test

After sending TPM2_Startup(), the system may use either TPM2_SelfTest() or TPM2_IncrementalSelfTest() to cause the TPM to perform tests of untested algorithms. TPM2_SelfTest() may optionally cause the TPM to perform a full self-test of all algorithms and functional blocks. Once these commands are issued, the TPM returns TPM_RC_TESTING for any command that requires use of any testable function until all requested tests are completed.

NOTE 2 FIPS 140-2 requires that all power-on self-tests be complete before the TPM returns any value that depends on the results of a testable function. If compliance with FIPS 140-2 is required, any command that requires use of an untested function causes the TPM to operate as if TPM2_SelfTest(fullTest = NO) was received. The TPM returns TPM_RC_TESTING and continues to return TPM_RC_TESTING until all tests are complete. Alternatively, it may complete all tests and then complete the command. It may also return TPM_RC_NEEDS_TEST.

NOTE 3 Authenticated tests may be generated by attaching an audit session to TPM2_GetTestResult() and then using TPM2_GetSessionAuditDigest() to obtain the signature.

If any self-tests fail, the TPM goes into Failure mode and does not allow execution of any Protected Capabilities except TPM2_GetTestResult() and TPM2_GetCapability(). The TPM exits Failure mode when it receives _TPM_Init.

12.4 Failure Mode

If the TPM fails an internal test, it enters Failure mode. While in Failure mode, the TPM returns TPM_RC_FAILURE in response to any command except TPM2_GetTestResult() or TPM2_GetCapability() (see Figure 7). While in Failure mode, the TPM is only required to provide a limited number of property values. They are all in the set of TPM properties (TPM_CAP_TPM_PROPERTIES):

- TPM_PT_MANUFACTURER
- TPM_PT_VENDOR_STRING_1
- TPM_PT_VENDOR_STRING_2
- TPM_PT_VENDOR_STRING_3
- TPM_PT_VENDOR_STRING_4
- TPM_PT_VENDOR_TPM_TYPE
- TPM_PT_FIRMWARE_VERSION_1
- TPM_PT_FIRMWARE_VERSION_2

NOTE An implementation is allowed to return other property values.

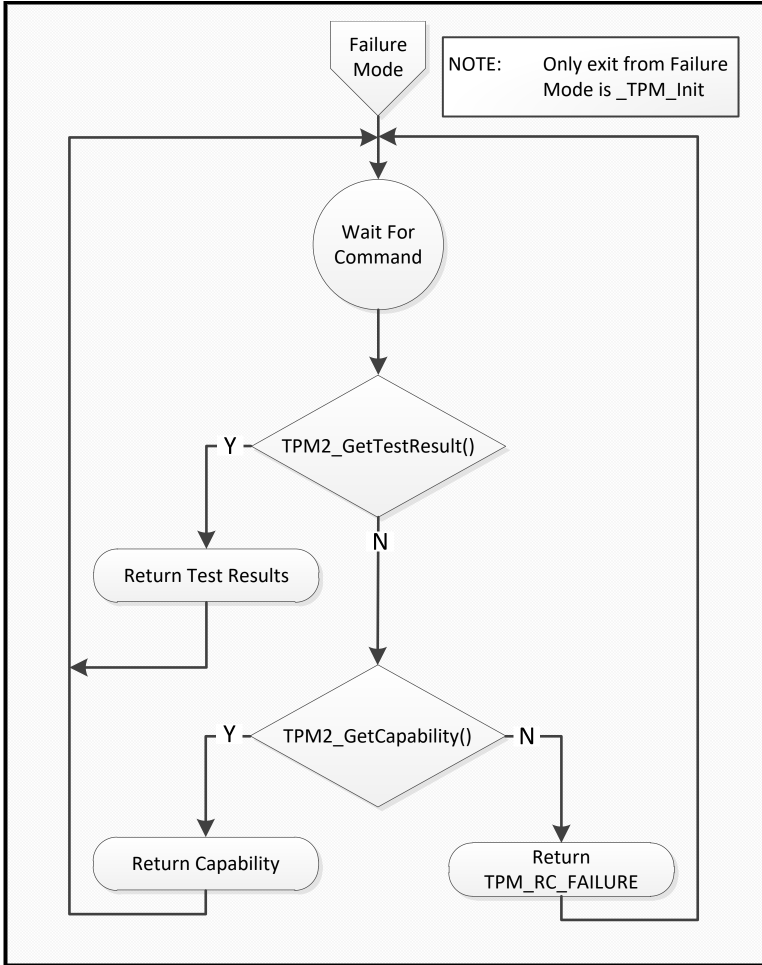

Figure 7 — Failure Mode Behavior

12.5 Field Upgrade

12.5.1 Introduction

This specification describes optional Protected Capabilities for upgrading the TPM firmware. The methods described in this specification would allow the upgrade process to be handled in a standard way on TPMs from multiple vendors. The methods described here should not be viewed as limiting the vendor's options for implementation of their own, vendor-specific methods for upgrading the TPM firmware. However, the field upgrade methods chosen by the vendor should not be less robust than the methods described in this specification. In particular, the authorizations for the upgrade should be the same as the field upgrade commands in this specification.

12.5.2 Field Upgrade Mode

This specification describes two optional upgrade methods: full and incremental. These terms do not refer to how much of the firmware in the TPM changes, but to how the upgrade is applied.

- For a full upgrade, the TPM stores in Shielded Locations all blocks of the firmware update. It makes no change to the executing firmware unless all the blocks are confirmed to be correct. The upgrade process may be interrupted or abandoned without affecting TPM functionality.

 Copyright © TCG 2006-2020

- For an incremental upgrade, firmware updates may be applied as each block is received. The TPM may not be fully functional if the upgrade process is abandoned.

The field upgrade process starts when the TPM receives a properly authorized TPM2_FieldUpgradeStart() (see Figure 6). That command contains the digest of a first block of the upgrade. If the next command is TPM2_FieldUpgradeData() and the digest of the data parameter (*fuData*) of the command matches the signed digest in TPM2_FieldUgradeStart(), the TPM accepts *fuData* as containing the upgrade data.

The TPM may buffer firmware update blocks and not change the firmware until its buffer is full. When a consequential change to the running firmware is made, the TPM enters Field Upgrade mode (FUM) and does not accept any command but TPM2_FieldUpgradeData() until the update is complete (see Figure 7). Before the TPM enters FUM

- it may accept other commands, and
- the update sequence may be abandoned by sending a zero-length upgrade data buffer. The TPM acknowledges that it has abandoned the field upgrade by returning TPM_ALG_NULL for *nextDigest*.

When the field upgrade process is complete, the TPM may either return to normal operation or enter a mode that requires _TPM_Init before normal TPM operations resume. The TPM vendor should determine if a reboot is required after the firmware update and cause the TPM to set the mode appropriately.

If the TPM is reset (_TPM_Init) while in FUM and the TPM is not able to revert to normal operation, three possibilities exist for recovery. The choice is determined by the digest of the first upgrade block provided to the TPM after _TPM_Init. The TPM may retain up to three digest values that it uses for comparison:

1) the digest of the first upgrade block of the current sequence to be used when the intent is to restart the current upgrade sequence from the start (called Digest C in Figure 8);
2) the digest of the first block of the firmware that was being replaced (called Digest P in Figure 8) to be used when the intent is to abort the upgrade and restore the previous firmware; and
3) the digest of the first upgrade block of the factory installed firmware (called Digest F in Figure 8) to restore the TPM to its factory state.

To enable option 2) above, the TPM may support TPM2_FirmwareRead() so that the software performing the upgrade can save a copy of the current TPM firmware in case the upgrade fails.

NOTE TPM2_FirmwareRead() may not be supported on a TPM even if the TPM can perform a field upgrade.

If _TPM_Init is received while the TPM is in FUM, then TPM Reset is required after the field upgrade completes, regardless of the nature of the firmware changes. This reset is required because the TPM does not accept TPM2_Startup() while in FUM, and the TPM will not reflect the state of the platform.

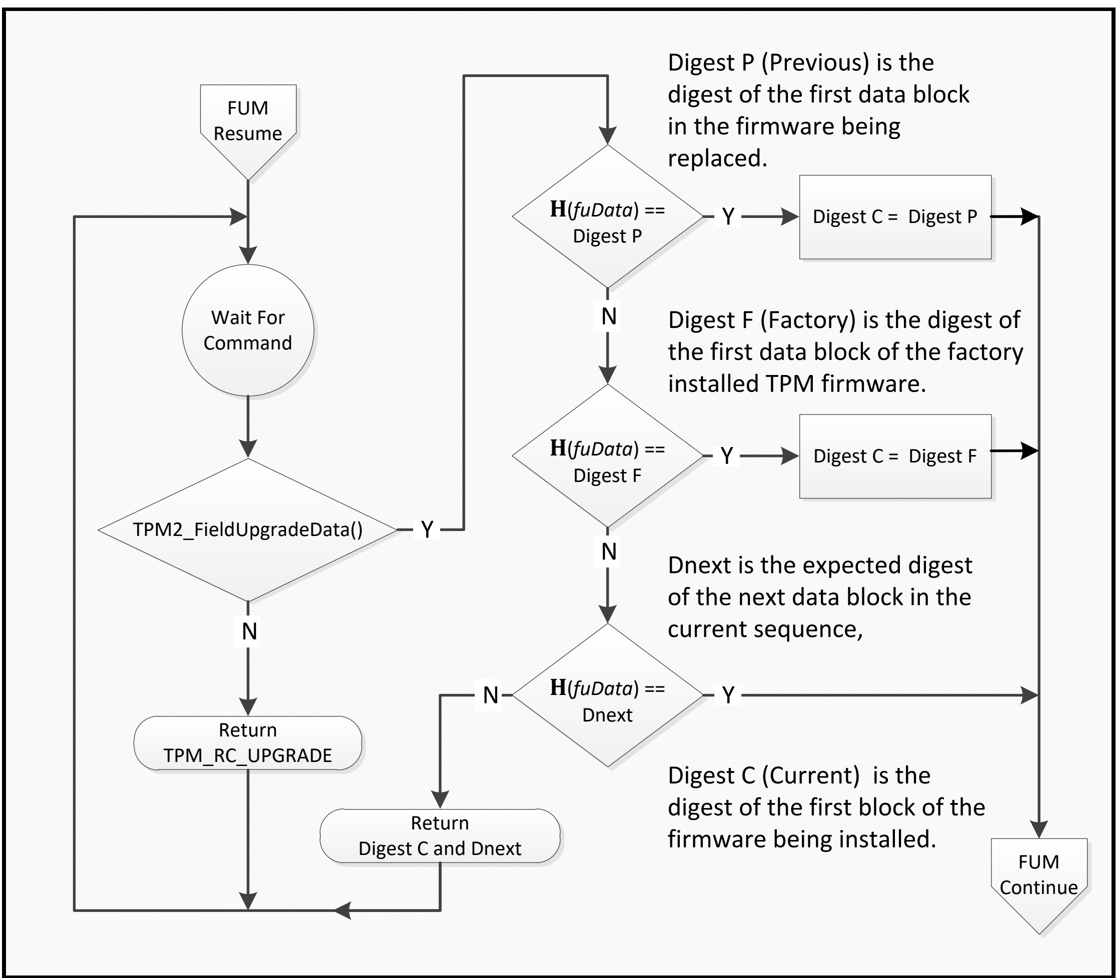

Figure 8 — Resuming Field Upgrade Mode after _TPM_Init

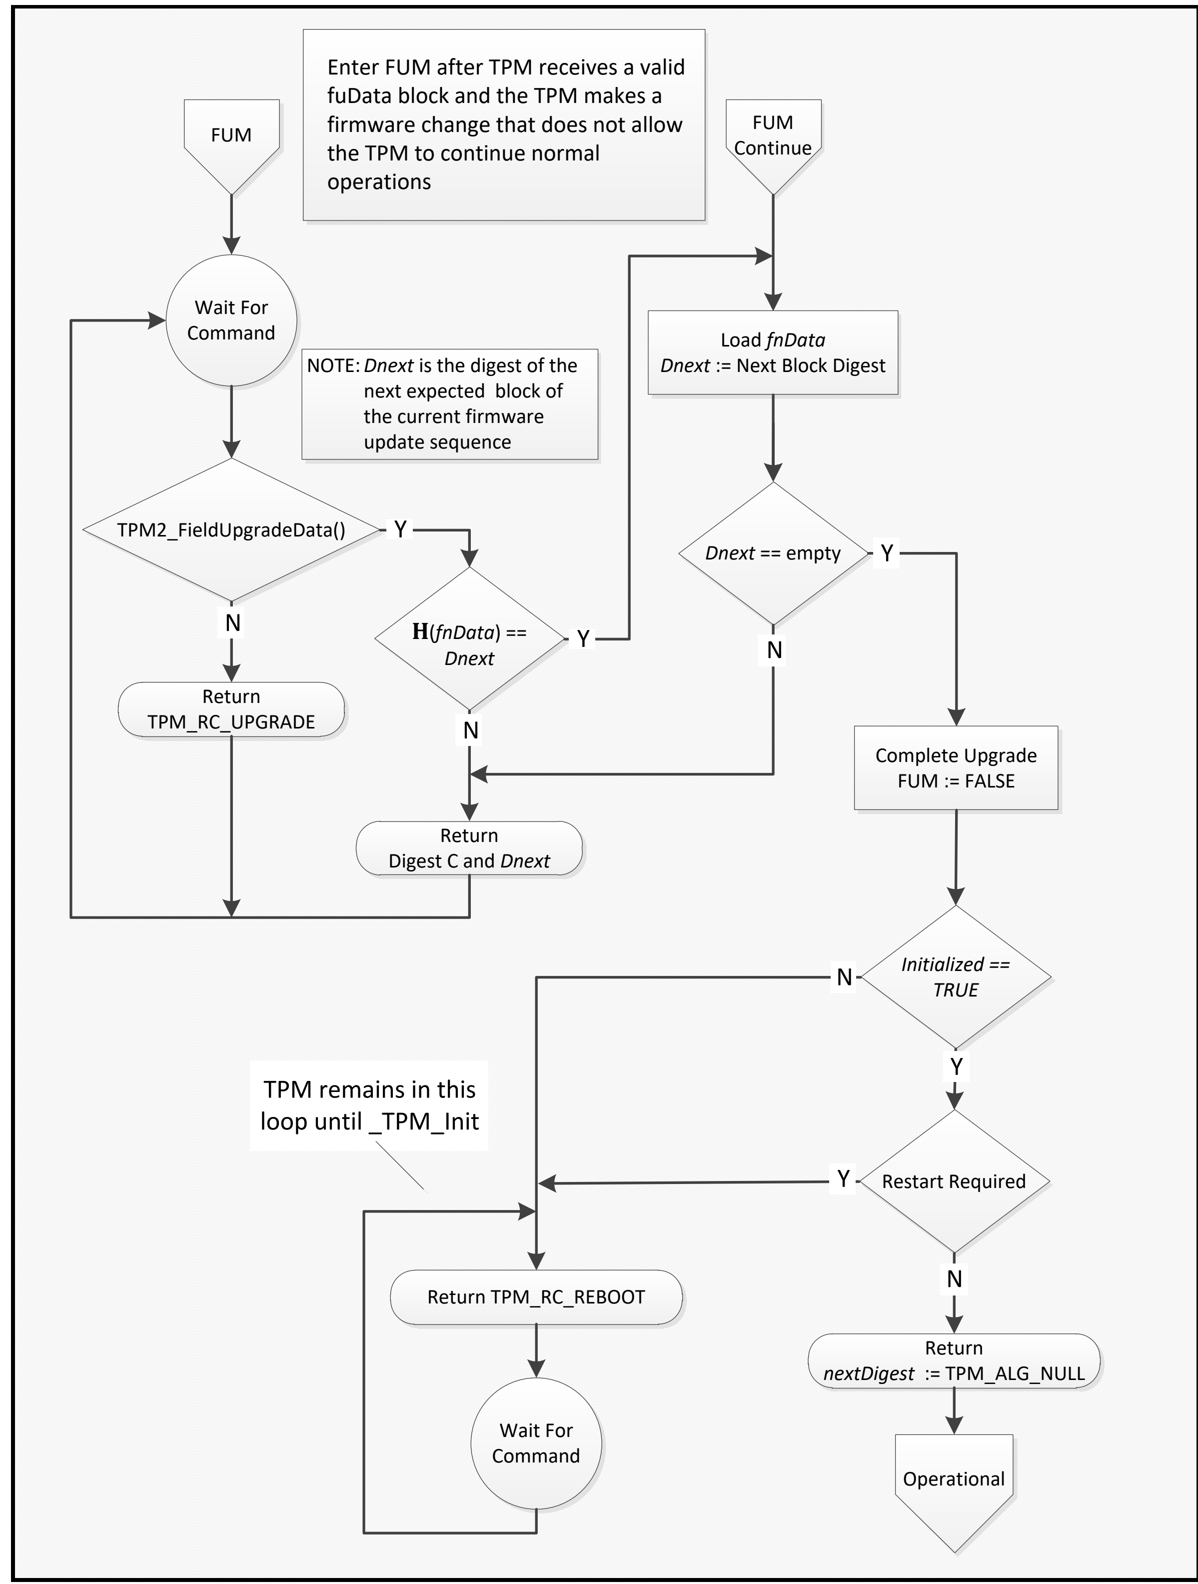

Figure 9 — Field Upgrade Mode

12.5.3 Preserved TPM State

A field upgrade may not cause exposure of any data that is specific to a TPM instance. This includes:

 Copyright © TCG 2006-2020

- Primary Seeds;
- Hierarchy *authValue*, *authPolicy*, and *proof* values;
- *lockoutAuth* and authorization failure count values;
- PCR authValue and authPolicy values;
- NV Index allocations and contents;
- Persistent object allocations and contents; and
- Clock.

In particular, if the TPM supports TPM2_FirmwareRead(), the returned data is not allowed to contain any data that is unique to the TPM instance.

A field upgrade should not cause the loss of any data that is specific to a TPM instance.

NOTE 1 A platform manufacturer may provide a means to change preserved data to accommodate a case where a field upgrade fixes a flaw that might have compromised TPM secrets.

12.5.4 Field Upgrade Implementation Options

The method described above for management of a TPM field upgrade is intended for use in a TPM that is implemented as stand-alone component (that is, when the TPM is manufactured and sold as a component that is added to a platform). When the TPM is not a stand-alone component, other methods of field upgrade are possible and are not precluded by this specification.

If other methods are used, the security of that method is the responsibility of the platform manufacturer.

 Copyright © TCG 2006-2020

13 TPM Control Domains

13.1 Introduction

Three entities control the TPM: the platform firmware, the platform Owner, and the Privacy Administrator. The Owner and Privacy Administrator are often the same entity. This control does not give these entities the ability to access user keys or data, but it does give them the ability to control selected TPM resources.

Each of the three entities has its own domain of control. Within that domain are TPM resources reserved to that entity. Each entity exercises its control over its domain by use of domain-specific authorization values.

The NV space defined by the platform firmware has an additional control, *phEnableNV*. When SET, NV space defined by the platform firmware is accessible. When CLEAR, it is inaccessible. This permits independent control of the platform firmware hierarchy and its NV space. For example, the platform hierarchy can be disabled while still permitting access to platform firmware NV space.

13.2 Controls

The platform firmware, platform Owner, and Privacy Administrator each have an authorization value and an authorization policy to control some portion of the TPM, including a specific Primary Seed (see clause 14). The authorizations, policies, and Primary Seed for each domain are:

- *platformAuth/platformPolicy*/PPS for platform firmware;
- *ownerAuth/ownerPolicy*/SPS for the Owner; and
- *endorsementAuth/endorsementPolicy*/EPS for the Privacy Administrator.

Associated with each hierarchy is a logical switch (that is, an "enable") that determines whether the hierarchy is enabled. These enables are *phEnable*, *shEnable*, and *ehEnable*.

When the enable for a hierarchy is SET (1) and the specification indicates that an action may be authorized with an authorization value, the corresponding policy is also allowed. For instance, when *phEnable* is SET and *platformAuth* is allowed, *platformPolicy* may also be used.

When the enable for a hierarchy is CLEAR, neither the corresponding *authValue* nor *authPolicy* may authorize operations.

The interaction of the two authorization types (value and policy) and the associated hierarchy enable are intended to provide a flexible set of controls. Table 2 shows the control combinations.

Table 2 shows the *authValue* as either being "Known" or "Unknown". These correspond to the enabled and disabled states for an *authValue*. When the *authValue* is known, it can be used for authorization, but it cannot be used when the *authValue* is unknown. Since a zero-length string (Empty Buffer) is a valid, knowable *authValue*; the way to make the *authValue* unknown, and disable its use, is to set it to a large random number and then discard that number.

Table 2 shows the *authPolicy* as either being "Set" or "Empty". These also correspond to the enabled and disabled states for an *authPolicy*. An *authPolicy* will have to match the value of a digest (*policyDigest*) in order for it to be a valid authorization. Since no digest has a zero length, setting the *authPolicy* to an Empty Buffer will disable use of the *authPolicy*. It is also possible to disable use of the *authPolicy* by setting it to any value that does not represent a known policy but the conventional way to disable use of *authPolicy* is to set it to an Empty Buffer (see 19.7 for the description of *policyDigest* generation and use).

 Copyright © TCG 2006-2020

Table 2 — Hierarchy Control Setting Combinations

hierarchy *enable*	*authValue*	*authPolicy*	Description
SET	Known	Set	The hierarchy is enabled, and objects in it may be loaded. Either authValue or authPolicy may manage resources related to the hierarchy.
SET	Unknown	Set	The authValue may be made unknown by setting it to a random value and then discarding the value. This prevents the authValue from being used. This combination is useful for keeping the hierarchy enabled but using a policy-based delegation scheme for managing hierarchy-related resources. An example is delegating control of creating Primary Objects in a hierarchy to one entity while delegating control of related NV resources to a different entity.
SET	Known	Empty	When the authPolicy is empty, it cannot match any policyDigest value so the use of authPolicy is disabled. This combination is most analogous to the control scheme of TPM 1.2, where an authValue (ownerAuth) is used to manage the resources of the single hierarchy supported by a 1.2 TPM.
CLEAR	N/A	N/A	When an enable is FALSE, the corresponding authValue and authPolicy may not be used to authorize any TPM action.

TPM2_HierarchyChangeAuth() may change the *authValue* associated with a hierarchy but only if the hierarchy is enabled. Either the *authPolicy* or the *authValue* of a hierarchy may be used to authorize a change to the *authValue*.

13.3 Platform Controls

The platform firmware has overall control of the TPM and the availability of the TPM to the platform Owner or Privacy Administrator. The platform firmware is assumed to be provided by the platform manufacturer and performs the management of the hardware in preparation for use by an operating system (the operating system may be provided by a different vendor). In some systems, platform firmware runs after the OS is loaded. Often this firmware is required to ensure the safety of the system.

EXAMPLE Some systems have thermal properties that, if not managed properly, could lead to destruction of the system, and could even lead to the system becoming a fire hazard.

If the firmware is crucial to the safety of the system, the platform manufacturer may design in a firmware update process that ensures that only firmware approved by the manufacturer for a specific machine is allowed to be loaded on the system. This firmware may use cryptography to validate the firmware update before it is loaded. The TPM has cryptographic functions that are similar or identical to the functions needed by the platform firmware for its management of the system. Rather than replicate those cryptographic capabilities, the platform firmware is given its own set of TPM resources for its use. Reuse of the TPM cryptographic capabilities by the platform is intended primarily as a cost savings.

The platform manufacturer decides if it is possible to disable use of the TPM by the platform. The method for disabling use of the TPM by the platform is platform-manufacturer specific.

The properties of the TPM required by the platform manufacturer need not match those of the Owner. The platform manufacturer decides what cryptographic algorithms are required to safeguard the platform. These algorithms may differ from the algorithms use by the Owner or the Privacy Administrator.

Platform controls allow the following operations not available to an ordinary TPM user:

- allocation of TPM NV memory;
- PCR configuration;

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

- control of the availability of any key hierarchies; and
- change of the PPS, SPS, and EPS and reset of associated authorization values and policy.

NOTE 1 This is not a comprehensive list. The uses of the platform controls are documented in TPM 2.0 Part 3. In that document, an authorization of a command that allows the use of the platform handle (TPM_RH_PLATFORM) indicates that the command accepts *platformAuth* or *platformPolicy*.

phEnable gates use of both *platformAuth/platformPolicy* and the PPS hierarchy, as described in the previous clause. When *phEnable* is CLEAR, a _TPM_Init is required to SET it.

On any _TPM_Init, *phEnable* is SET to ensure that the platform may use the TPM during its initialization.

On TPM Reset or TPM Restart, *platformAuth* is set to an EmptyAuth, and *platformPolicy* is set to an Empty Policy.

NOTE 2 Platform controls are reset on TPM Restart because the BIOS goes through a full initialization and has no memory of any previous authorization values.

NOTE 3 phEnable must be SET before TPM2_Startup when accommodating the case of an interrupted field upgrade that prevents startup from running. phEnable must be SET to permit field upgrade authorization.

A *platformAuth/platformPolicy* may be used in TPM2_HierarchyControl() to SET or CLEAR *shEnable* or *ehEnable*.

13.4 Owner Controls

The TPM controls available to the Owner are a subset of those available to the platform. These include

- allocation of TPM NV memory, and
- control of the availability of any storage hierarchies.

The s*hEnable* gates use of both *ownerAuth/ownerPolicy* and the SPS hierarchy, as described in 13.2.

The s*hEnable* is SET on each TPM Reset, TPM Restart, or when the SPS is changed (TPM2_Clear()). The s*hEnable* may be CLEAR (TPM2_HierarchyControl()) using either Lockout Authorization or Platform Authorization. When *shEnable* is CLEAR, it may only be SET (TPM2_HierarchyControl()) if Platform Authorization is provided.

The o*wnerAuth* and *ownerPolicy* values are persistent. They are set to standard initialization values when the SPS is changed (TPM2_Clear()): *ownerAuth* is set to an EmptyAuth, and *ownerPolicy* is set to an Empty Policy. They may be explicitly changed by designated commands.

13.5 Privacy Administrator Controls

The Privacy administrator has control over the Endorsement Hierarchy and reporting of privacy-sensitive data.

The Privacy Administrator uses *endorsementAuth* and *endorsementPolicy* to exercise its control. The Privacy Administrator has a more limited domain of control than those of the platform firmware and the Owner. The cases when *endorsementAuth* or *endorsementPolicy* are required are:

- when creating Primary Objects in the Endorsement hierarchy, and
- when controlling the availability of the Endorsement hierarchy.

 Copyright © TCG 2006-2020

Other actions that may be considered to be privacy-sensitive require use of objects in the Endorsement hierarchy. For example, certification of a TPM object by the TPM produces a data structure that has data that could allow cross-correlation of the objects. This data is obfuscated unless the certifying key is in the Endorsement hierarchy. The privacy administrator of the TPM is expected to manage the creation of objects in the Endorsement hierarchy to ensure that the use of those objects is in accordance with their privacy policy.

The e*hEnable* gates use of *endorsementAuth/endorsementPolicy* and the EPS hierarchy, as described in 13.1. It also gates use of the vendor-specific handles TPM_RH_AUTH_00 to TPM_RH_AUTH_FF. Additionally, when the SPS changes, the objects in the EPS hierarchy are flushed from the TPM, and new EPS objects (that is, Primary Objects) must be created.

NOTE Clearing the hierarchy is necessary to ensure that the new Owner may not abuse objects created by a previous one and so that objects belonging to the previous Owner may not compromise the new one.

The e*hEnable* is SET on each TPM2_Startup(TPM_SU_CLEAR) (that is, TPM Reset or TPM Restart) or when the SPS is changed (TPM2_Clear()). The e*hEnable* may be CLEAR using either Endorsement Authorization or Platform Authorization. When *ehEnable* is CLEAR, it may be SET using Platform Authorization

NOTE TPM2_HierarchyControl() will SET or CLEAR *ehEnable* if the proper authorization is provided.

The e*ndorsementAuth* and *endorsementPolicy* values are persistent. They are set to standard initialization values when the SPS (TPM2_Clear()) or EPS (TPM2_ChangeEPS()) are changed: *endorsementAuth* is set to an EmptyAuth, and *endorsementPolicy* is set to an Empty Policy. They may be explicitly changed by designated commands.

13.6 Primary Seed Authorizations

Use of a Primary Seed to create a Primary Object requires use of the authorization associated with that Primary Seed: Platform Authorization for the PPS, Owner Authorization for the SPS, and Endorsement Authorization for the EPS.

13.7 Lockout Control

A TPM is required to implement a lockout mechanism to protect against so-called “dictionary attacks,” where an attacker tries numerous authorization values until one succeeds. Dictionary attack protection is common for security devices, such as smartcards, that use human input for authorization. A human source of authorization likely has too little entropy to protect against an automated attack, so logic that prevents high-speed guessing of the values is required.

When the dictionary attack lockout is engaged, preventing use of some resources, it is helpful to have a secret value that resets lockout. The TPM stores the secret value as *lockoutAuth.* Alternatively, a policy *(lockoutPolicy)* can be used to reset lockout.

NOTE 1 The primary attack model for the dictionary attack begins when a system falls into the hands of a thief. The thief tries to recover data on the system by guessing the password used to protect a disk’s encryption keys. The dictionary attack logic defeats this attack by preventing the thief from making many guesses before the TPM locks out further attempts. When/if the system is returned to its rightful owner, that owner can enter the *lockoutAuth* value or satisfy *lockoutPolicy*, access the disk encryption keys, and return to normal operation.

NOTE 2 Unfortunately, dictionary attack logic is not forgiving of poor typing or a short memory. If someone types his or her password incorrectly due to clumsiness or poor memory, the dictionary attack logic might not differentiate this from an attack, so it locks the TPM. Lockout Authorization allows recovery from this situation.

 Copyright © TCG 2006-2020

The *lockoutAuth* value is reset to EmptyAuth and *lockoutPolicy* to the Empty Buffer when TPM2_Clear() is executed.

NOTE 3 TPM2_Clear() changes the SPS rendering all previously-created user objects inaccessible. There are, therefore, no keys for the dictionary attack logic to protect.

The l*ockoutAuth* value may be changed (TPM2_HierarchyChangeAuth()) only when its current value is provided. *LockoutPolicy* may be changed using TPM2_SetPrimaryPolicy().

Generally, dictionary attack protection is not applied to objects associated with the PPS or to NV Indexes defined using Platform Authorization. The platform firmware is expected to select a high-entropy value when setting the *platformAuth* after a TPM reset. Additionally, since Platform Authorization does not provide access to user data protected by the TPM, disclosure of *platformAuth* does not expose user secrets.

See 19.8 for full details on setting of parameters associated with dictionary attack logic and other aspects of the dictionary attack protection.

13.8 TPM Ownership

13.8.1 Taking Ownership

Taking ownership of a TPM is the process of inserting authorization values for the *ownerAuth*, *endorsementAuth*, and *lockoutAuth*.

A TPM that has been cleared (TPM2_Clear()) has its *ownerAuth*, *endorsementAuth*, and *lockoutAuth* values set to EmptyAuth and its *ownerPolicy, endorsementPolicy,* and *lockoutPolicy* values set to Empty Buffers. The OS is expected to change these values and manage them on behalf of the platform Owner.

The platform may prevent access to the hierarchies associated with Owner Authorization and Endorsement Authorization and prevent use of the TPM's persistent storage by the operating system and user applications. TPM cryptographic capabilities would still be available, and these could be used as if the TPM were a software cryptographic library.

13.8.2 Releasing Ownership

TPM2_Clear() clears the current Owner from the TPM. A persistent TPM control (TPMA_PERMANENT.*disableClear*) controls whether TPM2_Clear() is functional. If *disableClear* is CLEAR, then TPM2_Clear() may be authorized using either Platform Authorization or Lockout Authorization. If the control is SET, then TPM2_Clear() is not functional.

NOTE TPMA_PERMANENT.*disableClear* may be SET or CLEAR using platformAuth/platformPolicy, giving the platform the ability to enable execution of TPM2_Clear() when needed.

TPM2_Clear() instructs the TPM to:

- flush any transient or persistent objects associated with the SPS or EPS hierarchies (PPS objects are not affected);
- release any NV Index locations that do not have their TPMA_NV_PLATFORMCREATE attribute SET;
- set *shEnable* and *ehEnable* to TRUE;
- set ownerAuth, endorsementAuth, and lockoutAuth to an EmptyAuth;
- set ownerPolicy, endorsementPolicy, and lockoutPolicy to an Empty Policy;

- replace the existing SPS with a new value from the RNG; and
- recompute *shProof*, and *ehProof*.

14 Primary Seeds

14.1 Introduction

A Primary Seed is a large, random value that is persistently stored in a TPM; it is never stored off the TPM in any form. Primary Seeds are used in the generation of symmetric keys, asymmetric keys, other seeds, and proof values.

A Primary Seed generates Primary Objects using the methods described in Clause 27.5. In brief, the caller provides the parameters of an object to be created, and the TPM uses these parameters and the Primary Seed in a key derivation function (KDF) to produce an object of the desired type. After the TPM generates a Primary Object, it uses the parameters of that object and the Primary Seed to generate a symmetric key to encrypt the sensitive portion of the object (that is, the private data and authorizations). It then returns the public portion and name of the object to the caller. The Primary Object may then be context saved and loaded like any other object. It may be stored persistently in the TPM's NV memory (TPM2_EvictControl()).

Primary Seeds generate only Primary Objects. All other objects use the random number generator of the TPM as the source of entropy for generating secrets in the object.

14.2 Rationale

The algorithm flexibility provided by this specification makes it possible for the TPM to support many different asymmetric key types. TPM 1.2 supported only the RSA algorithm with a limited number of commonly used parameters. The addition of ECC support significantly increases the number of parameters because curve parameters may vary based on application.

While this flexibility is a major benefit of TPM 2.0, it creates new challenges for managing TPM Endorsement Keys (EKs) and EK certificates. As mentioned in 9.4.3.2, an EK is an identity for the Root of Trust for Reporting (RTR), and algorithm agility creates the possibility of having many identities for the same RTR, with each identity based on a different set of cryptographic algorithms.

One possible approach for handling many EKs and their associated certificates would be for the TPM manufacturer to have the TPM create EKs for many key parameters and store them on the TPM; in this way, a key with the correct parameters would be available in most situations. The TPM vendor could then create one or more certificates for those keys. However, this approach would require a prohibitive amount of NV memory to store all the key pairs and associated parameters. The approach taken in this specification allows certification of a large number of EKs with different parameters without requiring that any of them be stored in persistent TPM memory.

The mechanism of this specification uses a persistent, randomly generated seed value from which EKs are derived. The derivation process lets the TPM generate a different EK for each set of key parameters. As long as the seed value does not change, the same key parameters generate the same EKs.

The typical use of this EK generation approach is as follows: The TPM manufacturer or the platform manufacturer has the TPM create a new Endorsement Primary Seed (EPS) and then generate key pairs based on sets of input parameters and that EPS. The TPM retains the generated keys. Combinations of key parameters should be chosen to ensure that likely TPM users would find a combination to suit their needs. The manufacturer then generates one or more certificates for the generated public keys and then ships the TPM/system with no EK pair stored on it. The system owner decides which key types are needed, and the parameters for those types are entered into the TPM. If the parameters are the same as those used by the manufacturer, the TPM generates the same key pair. The system owner then has an EK with its certificate. Since an EK is not generally duplicable, the owner has a choice to make. They may either re-create the EK whenever it is needed or tell the TPM to save the EK in persistent memory.

 Copyright © TCG 2006-2020

The seed key concept may be applied to two other TPM key hierarchies: one used by platform firmware, and one used for the owner's Storage hierarchy. The Endorsement Keys (EK) are generated from the Endorsement Primary Seed (EPS), platform keys from the Platform Primary Seed (PPS), and Storage Root Keys (SRK) from the Storage Primary Seed (SPS). Each seed value has a different life cycle, but the way it seeds the associated hierarchies is approximately the same.

It is preferred that a TPM manufacturer generate a certificate for at least one EK before the device ships. This certificate would be based on the EPS that is present in the TPM at that time. While it is possible for the manufacturer to let the TPM populate the EPS and generate an RSA key pair, the unpredictability of the generation time may make injecting an EPS a more attractive option. The time taken to inject an EPS would be deterministic and one or more RSA key pairs could be generated for that EPS outside of the TPM. This could save considerable time during manufacturing.

The external algorithm for generating a key pair from the EPS has to be the same as the algorithm used by the TPM; otherwise, they will generate different keys. The generation times for the external and TPM processes will be proportional so the manufacturer can use the time for external key generation time as an indicator of the time that the TPM will take when the end user attempts to recreate the EK. If the manufacturer does decide to inject an EPS and generate RSA keys outside of the TPM, there is an opportunity to benefit the customer by discarding EPS values that result in long key pair generation times for the certified values.

Another possible option is to inject the EPS and a precomputed pair of RSA primes that are compatible with a specific template (compatible meaning that the primes are the right size and that the prime (p) and p-1 are not evenly divisible by the public exponent). The TPM could access those primes when the associated template is used for an EK. If this method is used, the TPM manufacturer has to make sure it is critical that the precomputed primes are only associated with a single template and that the primes are erased from the TPM when the EPS is changed.

The primary seed approach allows multiple storage hierarchies with differing security properties, as needed by various applications, without requiring that all of the SRKs occupy persistent TPM memory. An SRK may be made persistent in TPM NV memory if required by the application.

This scheme is also used in support of the Platform hierarchy for implementation simplicity.

14.3 Primary Seed Properties

14.3.1 Introduction

A Primary Seed is required to have at least twice the number of bits as the security strength of any symmetric or asymmetric algorithm implemented on the TPM.

EXAMPLE 1 RSA2048 is considered to have a security strength of 112 bits. If it were the strongest algorithm on the TPM, then the required size of an associated Primary Seed would be at least 224 bits.

EXAMPLE 2 If AES256 were implemented, the Primary Seed would be 512 bits even if: (1) the desired security strength is 196 bits, and (2) AES256 is used only for convenience, as is the case with Suite B.

A different authority controls each Primary Seed. In normal use, Primary Seeds are expected to have different lifetimes.

After a field upgrade that changes the Primary Seed strength, or that changes the algorithm that uses the Primary Seed, the TPM shall generate the original EKs corresponding to the EK certificates provisioned by the TPM manufacturer if the same template is provided to the TPM2_CreatePrimary() command until such time as TPM2_ChangeEPS command changes the EPS.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

For a field upgrade that does not change the Primary Seed strength or the algorithm that uses the Primary Seed and does not otherwise affect the security of Primary Objects based on the seeds, TPM2_CreatePrimary() with the same inputs should produce the same Primary Object in the platform, storage, and endorsement hierarchies after the field upgrade as it did before the field upgrade.

This requirement shall not be in effect for other keys derived from the EPS or for keys derived from the SPS or PPS.

EXAMPLE A field upgrade can cause TPM2_CreatePrimary() to generate a different key for the same input template. For example, revisions prior to revision 01.38 used KDFa, while revision 01.38 and after use DRBG. In addition, the security strength requirement could cause a change in the seed length if the field upgrade implements a stronger algorithm.

14.3.2 Endorsement Primary Seed (EPS)

The EPS is used to generate EKs and is the basis of the RTR's identity.

The TPM creates an EPS whenever it is powered on and no EPS is present. TPM2_ChangeEPS() may change the EPS (replace it with a new EPS), but this requires authorization by Platform Authorization.

The TPM manufacturer may inject an EPS and, under controlled conditions, compute the asymmetric EKs that the TPM would generate given specific input parameters. Only the TPM vendor may inject an EPS.

When an EPS is replaced, all objects in the Endorsement Hierarchy are invalidated, and certificates associated with the EKs generated from that EPS are no longer useful. This means that certificates for new EPS-based EKs may be needed. The environment in which this process occurs may not provide assurance that the EKs are generated from a genuine TPM. To support recertification in such an environment, the TPM allows cross certification of keys between the Platform hierarchy and the Endorsement hierarchy under control of the platform firmware. Cross certification allows a chain of trust to be maintained as the seeds are changed.

When a platform enters the distribution channel, it is expected to have a certificate for at least one EK for the TPM on that platform.

Either e*ndorsementAuth* or *endorsementPolicy* is required to use the EPS for creation of a Primary Object in the Endorsement hierarchy.

14.3.3 Platform Primary Seed (PPS)

The PPS is used to generate the hierarchy controlled by platform firmware. The hierarchies derived from this seed are for exclusive use by platform firmware and should not be made available to user-installable software (such as, OS and applications).

NOTE 1 The platform firmware may be changed because of actions by a person with possession of the platform, but that is not included in the definition of user-installable software.

The TPM creates a PPS whenever it is powered on and no PPS is present. TPM2_ChangePPS() may change the PPS (replace it with a new PPS), but this requires authorization by Platform Authorization.

A PPS may be injected but only by the TPM manufacturer.

Platform Authorization is required to use the PPS to create a Primary Object in the Platform hierarchy.

The authorization for use of objects in the PPS hierarchy should use a policy containing a reference to *platformAuth* and not be based on a key-specific authorization value.

NOTE 2 The TPM does not enforce this imperative.

 Copyright © TCG 2006-2020

NOTE 3 A simple way to achieve this control is to create a policy that references *platformAuth* in a TPM2_PolicySecret(). If the only component of the policy is TPM2_PolicySecret() referencing TPM_RH_PLATFORM, the policy may be the same for all objects in the Platform hierarchy and for all platforms that implement the chosen policy hash.

14.3.4 Storage Primary Seed (SPS)

The SPS is used to generate hierarchies controlled by the platform owner. This seed generates the keys that serve as Storage Root Keys for normal OS and application use.

The TPM creates the SPS whenever it is powered on and no SPS is present. TPM2_Clear() may be used to change the SPS if the TPM owner wants to ensure that no previously generated keys in the Storage hierarchy may be used in the future.

Changing the SPS invalidates all objects in the Storage Hierarchy and they cannot be recreated. Changing the SPS also invalidates all objects in the Endorsement Hierarchy and only the Primary Objects in the Endorsement Hierarchy may be recreated.

14.3.5 The Null Seed

The Null Seed is set to a random value on every TPM reset. The Null Seed can be used to generate hierarchies (primary objects and children of primary keys) that are only usable until the next TPM reset.

Objects in the null-hierarchy cannot be made into persistent objects. However, in other respects objects in this hierarchy behave like objects in the other hierarchy.

14.4 Hierarchy Proofs

The TPM uses a proof value to prove that it created or checked an externally provided value. A proof value is associated with a hierarchy and is statistically unique. The proof values are used in tickets. The tickets use the hierarchy-specific proof values. A ticket may not be used when its associated hierarchy is disabled.

EXAMPLE 1 The TPM may validate asymmetrically signed data. After doing so, it produces a ticket that is an HMAC over the signed data, with the HMAC key being a proof value. This proves to the TPM that it has already checked the asymmetric signature, so it does not have to do so again. Subsequently, when the TPM needs to check that the data was properly signed, it may use symmetric cryptography (a hash) rather than asymmetric cryptography to validate the signature.

EXAMPLE 2 When the TPM performs TPM2_ContextSave() on an object in the Storage hierarchy, it may include the Storage hierarchy proof (*shProof*) in the object’s integrity value. When the SPS is changed, *shProof* will change so that the saved contexts may not be reloaded.

A Platform hierarchy proof (*phProof)*, used for objects associated with the Platform hierarchy. *phProof* changes when the PPS changes. An *shProof*, used for the Storage and Endorsement hierarchies, changes when the SPS changes.

NOTE It is possible to create objects in the Endorsement Hierarchy that are not Primary Objects. Those Ordinary Objects are considered to belong to a specific TPM Owner. A change of the SPS indicates a change of Owner for the TPM. Inclusion of *ehProof* in the protection of Ordinary Objects in the Endorsement Hierarchy ensures that those Objects will be deleted when the Owner changes, because *ehProof* also changes when the Owner changes.

A proof is a value that may be kept in permanent storage on the TPM or it may be regenerated from the PPS or SPS on each boot or as needed. A proof value is never stored off the TPM in any form. Hierarchy proof values are only used as an HMAC key if the result of the computation is stored off the TPM. Examples are saved contexts and tickets. A hierarchy proof value may be used in other computations as long as the result of the computation does not leave the TPM.

 Copyright © TCG 2006-2020

The TPM should produce proof values that are the larger of either

- the size of the largest digest produced by any hash algorithm implemented on the TPM, or
- twice the size of the largest symmetric key supported by the TPM.

EXAMPLE 3 If the TPM implements SHA384 and AES256, the proof value will have a size of 512 bits.

NOTE According to SP800-57, the security strength of SHA256 in an HMAC function equals 256 bits. Since security strength is not improved when the key size is larger than the digest size, the recommendation for proof size provides the appropriate strength when the TPM is implementing balanced algorithm sets. A TPM using SHA256, ECC256, and AES128 is balanced, and the proof value is 256 bits.

 Copyright © TCG 2006-2020

15 TPM Handles

15.1 Introduction

TPM resources are referenced by handles that uniquely identify a resource that occupies TPM memory — either RAM or NV. A handle is a 32-bit value. Its most significant octet identifies the type of referenced resource. At any given instant, its low-order 24 bits identify a unique resource of that type. The actual resource identified by the low-order 24 bits may change with time.

A specific handle value may refer to only one TPM-resident resource at a time.

15.2 PCR Handles (MSO=00_{16})

To reduce confusion, PCR are assigned handles that have the same values as in previous versions of the specification. A PCR handle is an Index into an array of PCR. A PCR's Index and handle value are the same.

15.3 NV Index Handles (MSO=01_{16})

An NV Index is associated with a persistent TPM resource created by TPM2_NV_DefineSpace().

15.4 Session Handles (MSO=02_{16} and 03_{16})

The TPM assigns session handles when an authorization session is started (TPM2_StartAuthSession()). An HMAC session is assigned a handle with an MSO of 02_{16} and a policy session is assigned a handle with an MSO of 03_{16}. Each authorization session handle is associated with a unique context that may exist in only one place at a time: either on the TPM in a Shielded Location, or in a saved context as a Protected Object. The handle remains associated with the session as long as the session exists and does not change when the session is context-saved and reloaded.

The low order 3 octets of each session handle are unique. They are assigned interchangeably to HMAC or policy sessions but to only one at a time.

EXAMPLE 1 If a policy session has a value of 03 00 00 01_{16}, then an HMAC session with a value of 02 00 00 01_{16} will not be assigned at the same time.

NOTE 1 The policy and session handles are assigned from a common pool of handle values.

When TPM2_GetCapability() is used to obtain a list of sessions that are currently loaded on the TPM, the caller would use a handle with an MSO of 02_{16}. While this would normally be an HMAC handle reference, the TPM will respond with a list that includes both HMAC and policy sessions. The handles will be returned in ascending order of the low-order three octets.

EXAMPLE 2 A list of loaded handles returned by the TPM in response to a TPM2_GetCapability(*capability* = TPM_CAP_HANDLES, *property* = 02 00 00 00_{16}), the TPM might return the list: 02 00 00 02_{16}, 03 00 00 04_{16}, and 02 00 00 05_{16}

When TPM2_GetCapability() is used to obtain a list of sessions that are active but not on the TPM, the caller would use a handle with an MSO of 03_{16} which normally would reference a policy session. The TPM will respond with a list of session handles that are in use, but not on the TPM. Since the TPM does not keep a record of whether the saved session context was an HMAC or policy session, all of the handles in the list will have an MSO of 02_{16}.

The TPM is required to maintain a list of all, currently assigned session handles as well as the correct "version number" for any saved session contexts.

 Copyright © TCG 2006-2020

NOTE 2 the "version number" is how the TPM prevents replay of an authorization.

When an authorization session is no longer needed, TPM2_FlushContext() may be used to delete all context associated with the session from TPM memory (see 30.6). The session handle for this command may use an upper octet of either 02_{16} or 03_{16}.

NOTE 3 Flushing a session context deletes any data in the TPM relating to the context and frees the handle associated with that context and invalidates the version number of any saved context.

NOTE 4 An alternative method of flushing a session context exists that is not available for other entities. On the last use of the session, the caller may indicate (in one of the session attributes) that the session is no longer needed. If the command completes successfully, the TPM will complete the response computations for the session and delete the session context from TPM memory (see 18.6.4).

All session contexts in TPM memory are flushed on any TPM2_Startup(). The saved session contexts remain valid until a TPM Reset.

15.5 Permanent Resource Handles (MSO=40_{16})

Fixed resource handles refer to Shielded Locations that are always associated with the same handle. These resources have handles with an MSO of 40_{16}. Examples of these resources are Owner, Platform, and Endorsement hierarchy controls and the Lockout authorization value.

Another type of permanent resource handle is the vendor-specific authorization value. These optional resources may be populated with authorization values that are known only by the TPM manufacturer or some other privileged entity. The update of these authorization values is TPM-manufacturer-dependent.

If present, a vendor-specific authorization value can be used as a bind value within an authorization session or to authorize a policy using the TPM2_PolicySecret command. In the former case, an entity that knows the authorization value could create an auditable authorization session that only that entity could execute. In the latter case, the entity could create and/or use TPM resources with an authorization policy that only that entity could execute.

Since vendor-specific authorization values might be usable by an entity who knows them to identify the TPM, the use of these authorization values is under the control of the privacy administrator. These authorization values are only usable when the Endorsement Hierarchy is enabled as described in 13.5.

NOTE A use case for the vendor-specific authorization values is to recover in the field from a flaw in the TPM firmware. For example, TPM vendors may provide a mechanism that updates one or more of these authorization values based on the measurement of the TPM firmware. This update mechanism could be used to give the manufacturer confidence that a valid, uncompromised version of the TPM firmware is running. In this scenario, if the manufacturer wished to provide a certificate for an endorsement key generated in the field after a field upgrade to a trusted firmware version occurred, the manufacturer could use an auditable authorization session using the vendor-specific authorization value to verify the properties of the endorsement key and then create a certificate for that new endorsement key.

15.6 Transient Object Handles (MSO=80_{16})

The TPM assigns Object handles when an Object is loaded or when the Object's persistence is changed (TPM2_EvictControl()). Transient Objects in TPM RAM have handles with an MSO of 80_{16}; they may have a different value for the three LSOs each time the Object is used. This is because the Object's context may have been swapped out and the TPM assigned a new handle when the object was swapped back in. The TRM ensures that the handle references the correct object.

All Transient Objects are flushed from TPM memory on any TPM2_Startup(). A loaded Transient Object context may be flushed from TPM memory using TPM2_FlushContext() and indicating the handle of the loaded context to be flushed.

15.7 Persistent Object Handles (MSO=81_{16})

TPM2_EvictControl() may make a Transient Object into a Persistent Object. A Persistent Object, placed in the TPM's NV memory, is not cleared by a TPM2_Startup().

Making an Object persistent requires either Platform Authorization or Owner Authorization.

When the TPM changes a Transient Object to a Persistent Object, the caller indicates the handle to be assigned to the Persistent Object. The MSO of the handle is required to be 81_{16}. The next most significant bit is required to be CLEAR if the authorization is provided using Owner Authorization and SET if the authorization is provided using Platform Authorization. If the handle is not already in use, and space is available, a persistent copy of the Object is created and assigned the handle provided by the caller. This handle always references the same Persistent Object as long as it remains persistent. The handle assigned to a Persistent Object may be assigned to a new Persistent Object if the first Object is deleted from persistent storage.

 Copyright © TCG 2006-2020

16 Names

The Name of an entity is its unique identifier. The handle associated with an object may change due to context management (TPM2_ContextSave() / TPM2_ContextLoad()), but the Name of an object remains constant. The Name associated with an NV Index will change based on changes to the attributes of the Index.

EXAMPLE When an NV Index is initially defined, it will have a Name for an Index with TPMA_NV_WRITTEN CLEAR. After the Index is written, the Name will change to reflect that TPMA_NV_WRITTEN is SET for the Index.

When an NV Index becomes locked (TPMA_NV_WRITELOCKED or TPMA_NV_READLOCKED is SET), the Name of the NV Index changes. This has two implications:

The caller should use its copy of the NV public area and calculate the Name before using it in an HMAC authorization calculation. Otherwise, an invalid authorization may trigger the dictionary attack protection depending on TPMA_NV_NO_DA.

The TPM must check access control before checking authorization. For example, it should reject a read to a read locked NV Index before doing an authorization check that might trigger the dictionary attack protection.

The method of computing the Name for an entity varies according to the entity type that is the MSO of the handle. Table 3 shows the method and the handle's MSO for different entity types.

When the computation of a Name uses a hash algorithm, the algorithm identifier is included in the Name structure. If the Name is a handle, the Name is only the handle value.

Table 3 — Equations for Computing Entity Names

<table>
<tr><th>MSO of Handle</th><th>Entity Type</th><th>Equation for Computing the Name</th></tr>
<tr><td>00_{16}</td><td>PCR</td><td rowspan="4">$Name \coloneqq handle$
No hash is performed on the handle to produce the name and the name is only the size of the handle.</td></tr>
<tr><td>02_{16}</td><td>HMAC Session</td></tr>
<tr><td>03_{16}</td><td>Policy Session</td></tr>
<tr><td>40_{16}</td><td>Permanent Values</td></tr>
<tr><td>01_{16}</td><td>NV Index</td><td>$Name \coloneqq nameAlg \mid\mid \mathbf{H}_{nameAlg}(handle \rightarrow nvPublicArea)$
where
$nameAlg$ algorithm used to compute $Name$
$\mathrm{H}_{nameAlg}$ hash using the $nameAlg$ parameter in the NV Index location associated with $handle$
$nvPublicArea$ contents of the TPMS_NV_PUBLIC associated with $handle$</td></tr>
<tr><td>80_{16}</td><td>Transient Objects(1)</td><td rowspan="2">$Name \coloneqq nameAlg \mid\mid \mathbf{H}_{nameAlg}(handle \rightarrow publicArea)$
where
$nameAlg$ algorithm used to compute $Name$
$\mathrm{H}_{nameAlg}$ hash using the $nameAlg$ parameter in the object associated with $handle$
$publicArea$ contents of the TPMT_PUBLIC associated with $handle$</td></tr>
<tr><td>81_{16}</td><td>Persistent Objects</td></tr>
<tr><td colspan="3">NOTE 1) The Name of a sequence object is an Empty Buffer (see 32.4.5).</td></tr>
</table>

When an object is created, a "template" for the public area is used to define the properties for the new object. That template has the structure of an object's public area. The Name of a public area template is computed in the same way as the Name of a Transient Object.

 Copyright © TCG 2006-2020

17 PCR Operations

17.1 Initializing PCR

All platform configuration registers (PCR) are reset to their default initial condition on TPM Reset and TPM Restart. Some PCR may be designated as being preserved by TPM Resume. Those that are preserved are restored to the state that they had at the last TPM2_Shutdown(STATE) operation. When TPM2_Startup() completes successfully, PCR that are not designated as being preserved by TPM Resume will be in their default initial condition.

If allowed by its attributes, a PCR may also be reset by TPM2_PCR_Reset() or by a Dynamic Root of Trust (D-RTM) sequence (see 34.2). PCR attributes are defined in a platform-specific specification. They determine the reset value of a PCR as well as the localities required to perform the reset.

The default initial condition for any PCR, other than PCR[0], is either all bits CLEAR or all bits SET. For PCR[0], the default initial condition may all bits CLEAR, all bits SET, the locality at which TPM2_Startup() was received, or an indicator that the first measurement came from an H-CRTM. Other platform types may use other means of identifying the locality of the access.

A platform-specific specification may choose from the options list above.

EXAMPLE 1 A platform-specific specification may designate that the default initial condition for PCR[0-16] is all zeros, and for PCR[17-20], it is all ones.

EXAMPLE 2 A platform-specific specification may designate that the default initial condition for PCR[0] is the locality indicator and that PCR[1-16] have an initial condition of all zeros.

NOTE The locality indicator is an integer value between 0 and the maximum locality implemented on a TPM. Currently, the maximum hardware locality is 4. In a TPMA_LOCALITY, a locality of four would be represented by the octet $0001\ 0000_2$. When encoded for a PCR initial value, locality 4 would be represented by the octet $0000\ 0100_2$.

EXAMPLE 3 A virtual TPM may use a unique identifier for each of the software entities that might access it. If specific software is associated with a specific PCR, then the reset value of that PCR may be the unique identifier of the software that is allowed to change it.

TPM2_PCR_Reset() requires that the proper authorization be provided for the operation (see 17.7).

17.2 Extend of a PCR

Other than reset, described above, the only way to change a PCR value is to Extend it. The Extend operation on a PCR is defined as

$$PCR_{new} \coloneqq \mathbf{H}_{alg}\left(PCR_{old} \mid\mid digest\right) \tag{13}$$

After each Extend, the PCR value is unique for the specific order and combination of digest values that were Extended.

Except for D-RTM, authorization is required to extend a PCR (see 17.7).

17.3 Using Extend with PCR Banks

TPM2_PCR_Extend() has a handle to indicate the PCR to Extend and the data to be Extended. Extended data is a structure that contains one or more digests along with the algorithm identifier for the digest(s). Each digest is Extended to the PCR bank that has the same algorithm. If no digest data is provided for one of the PCR banks, no change is made to the PCR in that bank.

 Copyright © TCG 2006-2020

The TPM should perform the following operation for each algorithm in which *pcrNum* is defined:

$$PCR.digest[pcrNum][alg]_{new} \coloneqq \mathbf{H}_{alg}(PCR.digest[pcrNum][alg]_{old} \,||\, digest) \tag{14}$$

where

$\mathbf{H}_{alg}$	hash function using the algorithm associated with the PCR instance
$PCR.digest$	digest value in a PCR
$pcrNum$	PCR numeric selector
alg	PCR algorithmic selector
$digest$	digest part of the list entry that has the same algorithm identifier as the PCR bank

EXAMPLE If a TPM supports three PCR banks (such as, SHA-1, SHA256, and SHA512), then an Extend to PCR[2] with a SHA-1 digest and SHA256 digest would be Extended to PCR[2] in the SHA-1 bank, and the SHA256 digest would be Extended to PCR[2] in the SHA256 bank. There would be no change to any PCR in the SHA512 bank.

17.4 Recording Events

An alternative way to record log entries is to input the full log entry to the TPM rather than performing the digests outside the TPM. This performs a hash on the log entry for each of the hash algorithms supported by the TPM. Events no larger than 1024 octets may use TPM2_PCR_Event(). Events exceeding 1024 octets may use the sequence commands: TPM2_HashSequenceStart(), TPM2_SequenceUpdate(), and TPM2_EventSequenceComplete()).

TPM2_PCR_Event() and TPM2_EventSequenceComplete() return a list of tagged digests. The digests are the digests of the event data using each implemented hash algorithm.

EXAMPLE For a TPM implementing two algorithms (such as, SHA256 and SM3), the event commands return a list of two tagged digests.

TPM2_EventSequenceComplete() requires that proper authorization be provided (see 17.7).

Recording of an event may also occur as the result of a _TPM_Hash_Start/_TPM_Hash_Data/_TPM_Hash_End sequence (an *H-CRTM Event Sequence*). The indications for the H-CRTM sequence come from the TPM interface and not through the command buffer. On receipt of _TPM_Hash_Start, the TPM will created an Event Sequence context. If no object context space is available when the TPM receives _TPM_Hash_Start, the TPM will flush a context (vendor's choice) in order to create the Event Sequence context. _TPM_Hash_Data is used to update the H-CRTM Event Sequence context and _TPM_Hash_End completes the sequence. The digest or digests computed during the H-CRTM Event Sequence will be extended into the PCR designated by the relevant platform-specific specification. A platform-specific specification may allow an H-CRTM Event Sequence before or after TPM2_Startup(). An H-CRTM Event prior to TPM2_Startup() affects PCR[0]. After TPM2_Startup(), an H-CRTM Event affects PCR[17].

17.5 Selecting Multiple PCR

TPM2_PCR_Event() implicitly selects all PCR with the same Index. Some commands allow the selection of multiple PCR in different banks. Examples are TPM2_PCR_Read(), TPM2_Quote(), and TPM2_PolicyPCR() that allow the caller to make arbitrary selections of PCR in multiple banks.

 Copyright © TCG 2006-2020

When a command allows multiple PCR to be selected, a list of selectors is used. Each entry in the list consists of an algorithm ID followed by a bit array. Each bit in the bit array corresponds to one PCR. If a bit is SET, then the indicated PCR in the bank corresponding to the algorithm ID is selected.

The bit correspondence to PCR is that the bit corresponding to PCR[n] is the ($n \bmod 8$) bit in the $\lfloor n/8 \rfloor$ octet of the array.

EXAMPLE An array to select PCR[0] and PCR[13] in a TPM with 16 PCR would be 01 20_{16}. The bit for PCR[0] is the 0 **mod** 8 = 0th bit in the $\lfloor 0/8 \rfloor = 0^{th}$ octet (the octet with the 01_{16} value) and the bit for PCR[13] is the 13 **mod** 8 = 5th bit in the $\lfloor 13/8 \rfloor = 1^{st}$ octet (the octet with the 20_{16} value).

The list of selectors is processed in order. The selected PCR are concatenated, with the lowest numbered PCR in the first selector being the first in the list and the highest numbered PCR in the last selector being the last.

TPM2_PCR_Read() returns a list of PCR values that correspond to the PCR selected in the selector list. TPM2_Quote() and TPM2_PolicyPCR() digest the concatenation of PCR.

It is not an error for the PCR selection to indicate a PCR that is not implemented in a bank. No value is included in the concatenation of PCR for an unimplemented PCR. It is an error if the algorithm ID selects a hash algorithm that is not implemented.

17.6 Reporting on PCR

17.6.1 Reading PCR

TPM2_PCR_Read() reads the current values of a selection of PCR. For this command, the caller indicates a list of PCR to be read using a PCR selection structure. This structure is an array of lists. Each array entry has a hash identifier and a bit field. The hash identifier indicates the bank of PCR, and the bit field indicates the PCR being selected in the bank.

In the response, the TPM provides a PCR selection structure and a list of PCR values. The PCR selection structure indicates the PCR that are present in the return structure. The size of the requested return data structure may not fit in the available TPM output buffer. In that case, the list of PCR values is truncated, and the response PCR selection structure indicates the PCR that were returned. If the returned structure does not contain all of the PCR, the caller may modify the selection structure and make another read request to get additional PCR values.

Since the PCR may change between the calls to collect the full set of PCR of interest, the TPM returns a counter that increments on most invocations of TPM2_PCR_Extend(), TPM2_PCR_Event(), TPM2_EventSequenceComplete(), or TPM2_PCR_Reset() (see 17.9 for exemptions). If this counter value changes between calls, the sequence may need to be repeated until the desired PCR are all returned with no change to the counter value.

17.6.2 Attesting to PCR

In some cases, it is necessary for selected PCR to be in a specific state. When indicating that state, it is not desirable to have to list the contents of each PCR. Instead, a digest of a concatenation of PCR (a composite PCR digest) will indicate the current contents of all of the PCR of interest.

The PCR to be included in the composite digest are selected by the same type of structure used for TPM2_PCR_Read(). The selection structure is first filtered so that unimplemented PCR are not in the selection structure. Then, a composite digest of all of the selected PCR is created. Finally, the filtered selection structure and the composite digest are hashed to create the final digest value. That digest may be compared to a required digest (TPM2_PolicyPCR()) or returned in an attestation (TPM2_Quote()).

 Copyright © TCG 2006-2020

To validate an attestation quote, a remote caller will typically use the PCR to recalculate the digest value. The TPM 1.2 quote command returns the PCR values along with the digest. In TPM 2.0, because of hash agility, the PCR set could have exceeded the response buffer size. Therefore, TPM2_Quote() returns only the digest, and the PCR values must be retrieved separately.

This can lead to a race condition. The PCR values can change between the time of the quote and the time they are read. There are several solutions. The PCR can be read before and after the quote to ensure that they did not change. Alternatively, the quote digest can be validated locally against the PCR before returning results to a remote caller, and the quote can be rerun until the validation succeeds.

17.7 PCR Authorizations

TPM2_PCR_Reset(), TPM2_PCR_Extend(), TPM2_PCR_Event(), and TPM2_EventSequenceComplete() require authorization for the PCR being modified. The type of the authorization may differ based on the PCR being modified. A PCR may be defined as having a fixed, EmptyAuth; a variable *authValue;* or a variable *authPolicy*.

The authorization (*authValue* or *authPolicy*) for a PCR may apply to a set of PCR. That is, several PCR may be designated as using the same authorization value so that changing the authorization value (*authValue* or *authPolicy*) of any PCR in the set will change the value for all PCR in the set. A set of PCR that are authorized by an *authValue* are in an *authorization set*. A set of PCR that are authorized by an *authPolicy* are in a *policy set*.

The type of authorization associated with each PCR is fixed by a platform-specific specification. For each set, the platform-specific specification defines the PCRs that are in the set. A PCR should not be in more than one policy set or one authorization set.

A PCR may be in both a policy set and an authorization set. If it is in both, the only way to use the *authValue* of the authorization set is with a policy that contains TPM2_PolicyAuthValue() or TPM2_PolicyPassword().

An indication of the PCR in an authorization set may be read using TPM2_GetCapability(*capability* == TPM_CAP_PCR_PROPERTIES, *property* == TPM_PT_PCR_AUTH) and the PCR in a policy set may be read using TPM2_GetCapability(*capability* == TPM_CAP_PCR_PROPERTIES, *property* == TPM_PT_PCR_POLICY).

NOTE 1 The reference implementation only provides support for one set of each type. If additional sets are needed, the property types for TPM_CAP_PCR_PROPERTIES may be extended.

NOTE 2 If a PCR is in multiple policy or authorization sets, the TPM will use the policy or authorization of the lowest numbered set. That is, the set with the lowest TPM_PT_PCR_POLICY or TPM_PT_PCR_AUTH property.

To authorize a PCR, the correct authorization type is required, which will depend on the authorization set of a PCR. In all cases, The EmptyAuth value may be provided in either an HMAC session using a zero-length *authValue* in the HMAC calculation or as a zero length password.

17.7.1 PCR Not in a Set

If the PCR is in no set, then the authorization may only be with an EmptyAuth value.

17.7.2 Authorization Set

If the PCR is in an *authorization set,* then the *authValue* of the PCR is provided either with an HMAC session or in a password. When a PCR has a fixed, EmptyAuth value, an authorization session is still required.

 Copyright © TCG 2006-2020

When a PCR has a variable *authValue*, that *authValue* is reset to an EmptyAuth on each STARTUP(CLEAR). It is preserved across STARTUP(STATE). A variable *authValue* may be changed using TPM2_PCR_SetAuthValue() by an entity with knowledge of the *authValue*.

17.7.3 Policy Set

An *authPolicy* for a policy set has both a hash algorithm and a digest value.

If the hash algorithm for the *authPolicy* is TPM_ALG_NULL, the policy has not been set. This *uninitialized policy set* will use an EmptyAuth.

If the digest algorithm for the policy is not TPM_ALG_NULL, then the policy set is an *initialized policy set*. If the PCR is in an initialized policy set, then the authorization may only be given with a policy session.

The hash algorithm for all policy sets is set to TPM_ALG_NULL by TPM2_ChangePPS(). The algorithm and *authPolicy* associated with a PCR may only be changed using TPM2_SetAuthPolicy() by an entity with knowledge of the Platform Authorization.

If an HMAC session or a password is used for a PCR in an initialized policy set, then the TPM will return an error (TPM_RC_AUTH_TYPE). If a policy session is used for a PCR that is not in an initialized policy set, then the TPM will return an error (TPM_RC_POLICY_FAIL). Neither of these two failures would cause an update of the dictionary attack protection.

17.7.4 Order of Checking

When determining the correct type of authorization for a PCR, the TPM will use the authorization type. If the authorization is a password or HMAC session, The TPM will check to see if the PCR is in an authorization set.

17.8 PCR Allocation

A TPM may support reallocation of the PCR by the platform. To change the allocation of PCR, the platform would use TPM2_PCR_Allocate(). The allocation structure has a PCR selection for each implemented hash algorithm. To allocate a PCR in a bank, the corresponding bit would be SET in the selection for that bank.

The TPM2_PCR_Allocate() changes to PCR allocation take effect upon the next _TPM_Init and persist until the next TPM2_PCR_Allocate().

NOTE 1 Because of RAM limitations, an implementation may not allow arbitrary allocation of PCR within a bank. This does not create a deployment issue as the platform is expected to be able to manage the TPMs that would be attached to that platform.

An allocation may not be made for PCR if the attributes for the PCR are not defined by the platform-specific specification of that TPM.

NOTE 2 The attributes for a PCR include the Startup() initialization value, the locality for reset, and the locality for extend.

There is a requirement that a bank exists for each hash algorithm but there is no requirement that the bank have any PCR (that is, all selection PCR selection bits for the bank may be CLEAR).

It is a valid implementation for the TPM to ship with a specific PCR allocation that is not changeable. If the TPM does not allow the changing of the allocation, it would not implement TPM2_PCR_Allocate().

 Copyright © TCG 2006-2020

17.9 PCR Change Tracking

To support the use of PCR in policy the TPM maintains a *pcrUpdateCounter.* In general, this counter is incremented each time a PCR is modified (either extended or reset). This counter is used when a policy requires that PCR have a specific value (see 19.7.7.6).

A platform-specific specification may designate that updates of selected PCR will not cause a change to *pcrUpdateCounter*.

A bitmap of the PCR that can be updated without changing *pcrUpdateCounter* can be read with TPM2_GetCapability(*capability* == TMP_CAP_PCR_PROPERTY, property == TPM_PT_PCR_NO_INCREMENT).

17.10 Other Uses for PCR

The PCR-related commands defined in this library cover common use cases: for example, logging of components during boot or a runtime-switch in the TCB. Platform-specific specifications define PCR attributes that control this behavior and describe how PCR should be used by external software.

However, PCR are designed for more generalized representation of platform state, and platform-specific specifications may define additional PCR behaviors that capture this. Generally, a platform specification may define a PCR to represent any value that is authoritatively known by the TPM or has been securely communicated to the TPM. For instance, a TPM for a “trusted lock” might define a PCR that has value of zero to indicate that a door is closed, and one to indicate that a door is open or a virtual-TPM specification might define a PCR that has a value that represents some characteristic of the virtual machine that is issuing the TPM command. This specification demands no particular behavior or value-semantics for such PCR.

NOTE A PCR can "represent" a value either by having the PCR set to that value or by having the PCR extended with the value. In the case of the "trusted lock," it is more likely that the PCR would contain either a zero or one to represent the state of the lock than that each change to the lock be extended to a PCR.

This does not mean that the platform-specific working groups are allowed to define new commands to operate on PCR.

 Copyright © TCG 2006-2020

18 TPM Command/Response Structure

18.1 Introduction

A command is a TPM Protected Capability that indicates an operation to be performed by the TPM. It contains from one to five components, in the following order:

1) a command header that indicates the overall size of the command, the command code, and a tag indicating whether the Authorization Area is present;
2) a command-dependent number (zero to three) of handles identifying the Shielded Locations with/on which the command (Protected Capability) operates;
3) a 32-bit value indicating the size of the Authorization Area;
4) an Authorization Area containing one to three session structures; and

NOTE Components 3 and 4 always occur together. The authorization size parameter is not present if there are no sessions in the Authorization Area.

5) a command-dependent parameter area containing qualifying information for the command.

A response contains

1) a response header that indicates the overall size of the response, the response code, and a tag indicating whether the Authorization Area is present;
2) a command-dependent number (zero or one) of handles identifying the Shielded Locations with/on which the command (Protected Capability) operates;
3) a 32-bit value indicating the size of the parameter area;
4) a command-dependent parameter area containing the values produced by the TPM; and
5) an Authorization Area containing one to three session structures.

NOTE Components 3 and 5 always occur together. That is, if the Authorization Area is empty, the 32-bit value for the parameter size will not be present.

As with the command, the formats for the remaining areas of the response are dependent on the value of the associated command code. The session and parameter area order are reversed in a response.

The ordering of authorization structures and command-dependent parameters is intended to minimize TPM complexity. In a command, the authorization structures are first in order that the TPM can generate its authorization digests from the command-dependent parameters as they arrive. In a response, command-dependent parameters are first in order that the TPM can use the output buffer to assemble the command-dependent parameters prior to generating its authorization digests.

NOTE: In traditional implementations, all of the octets of a command are available at the same time so skipping around in the data structure was not an issue. In some anticipated implementations, this will not be the case and the processing of a command or response will need to be more linear.

For tables in this specification, the separators indicating the demarcations between the header, handle, authorization, and parameter components are shown in Table 4.

 Copyright © TCG 2006-2020

Table 4 — Separators

Separator	Meaning
	This type of separator is followed by one or more handles.
	In a command, this type of separator is followed by a 32-bit value indicating the number of octets in the *Authorization Area*. In a response, it is followed by a 32-bit value indicating the number of *parameter* octets (present only if tag for command/response is TPM_ST_SESSIONS).
	This type of separator is followed by one or more session structures (present only if tag for command/response is TPM_ST_SESSIONS).
	This type of separator is followed by one or more parameters

Figure 10 and Figure 11 show the basic layout of a TPM command and response (see 18.9 for a detailed example command and 18.10 for a detailed example response).

header
{ handles }
Number of handles is command-dependent and may be zero
{ authorizationSize }
{ Authorization Area }
One or more sessions
{ parameters }
Contents are commandCode-dependent

Figure 10 — Command Structure

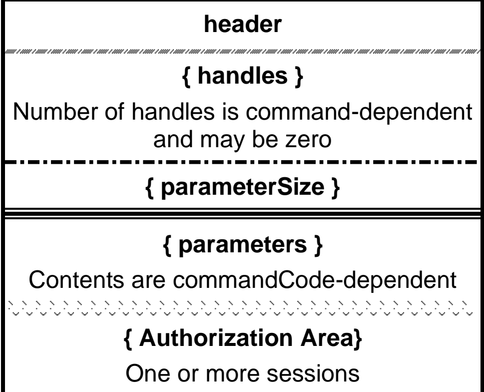

Figure 11 — Response Structure

NOTE Not all sessions in the Authorization Area are required to be used for authorization. Sessions may also be used for audit or parameter encryption.

18.2 Command/Response Header Fields

A command or response header always contains three values, displayed in Figure 12.

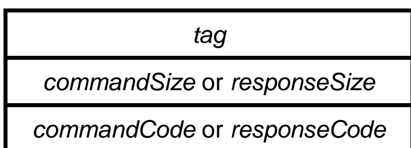

Figure 12 — Command/Response Header Structure

 Copyright © TCG 2006-2020

18.2.1 tag

A *tag* is present in all commands sent to the TPM and in responses received from the TPM. The *tag* indicates whether a command is formatted according to TPM 1.2 or this 2.0 specification. If the latter, the *tag* indicates if any session data is present.

Table 5 lists the *tag* values used for commands and response defined in this specification.

NOTE The tags for commands defined in this specification indicate only whether the command uses one or more sessions, and do not indicate the number of sessions present in the Authorization Area. Each session structure that uses a variable session handle follows the same format, which may be parsed to find the start of the next session.

Table 5 — *Tag* Values

Value	Description
TPM_ST_NO_SESSIONS	This value indicates that the command or response is formatted according to this specification and that the Authorization Area is empty. It is used in a response if the command used this tag or if the command did not complete successfully.
TPM_ST_SESSIONS	This value indicates that the command or response is formatted according to this specification and that the Authorization Area contains one or more authorizations. It indicates that the *authorizationSize* value is present; in a response, it indicates that the *parameterSize* value is present.

18.2.2 commandSize/responseSize

The *commandSize*/*responseSize* value indicates the total number of octets of this command/response, starting with the first octet of *tag.*

18.2.3 commandCode

The *commandCode* appears only in the command to the TPM. It indicates the operation that the TPM should perform and the formats of the handle and parameter areas for the command and response. The *commandCode* parameter is included in the command parameter hash (*cpHash*) and the response parameter hash (*rpHash*).

18.2.4 responseCode

The *responseCode* appears only in the response from the TPM. A *responseCode* of TPM_RC_SUCCESS (zero) indicates that the TPM has successfully completed the command and, depending on the command format, that the handle, parameter, and authorization components are present.

A non-zero *responseCode* indicates an error or fault. In this case, *tag* will be TPM_ST_NO_SESSIONS, and *responseSize* is 10, indicating that no octets follow the *responseCode*. No handle, parameter, or session response components are present.

18.3 Handles

Handles are TPM-assigned values that let the caller indicate the TPM-resident structure that a command is to manipulate. That is, the handle identifies the Shielded Location with/on which a Protected Capability is to operate. Some TPM commands (such as, TPM2_Startup()) require no handles.

 Copyright © TCG 2006-2020

The number of handles in the command and in the response is implied by the *commandCode*. It also indicates the command handles that have an associated authorization session. Handles that require authorization in an associated authorization session are listed ahead of handles that do not have an associated authorization session.

EXAMPLE TPM2_ObjectChangeAuth() has two handles, one (*objectHandle*) that uses an authorization session, and one (*parentHandle*) that does not. The standard command syntax requires that *objectHandle* occur first.

A response may have handles only if the *responseCode* is TPM_RC_SUCCESS.

The architectural limit for the number of handles in the handle area is seven. This limit is determined by the error-reporting scheme.

NOTE No currently defined command uses more than three handles.

18.4 Parameters

The *commandCode* indicates the structure of the optional handle and parameter areas. The contents of these parameter areas differ for commands and responses. Some TPM commands (such as, TPM2_Clear()) require no parameters.

All parameter values and the *commandCode* are included in the *cpHash* or *rpHash*. *authorizationSize* is not included in the *cpHash*, and *parameterSize* is not included in the *rpHash*.

NOTE 1 If a parameter is encrypted, it is included in the *cpHash/rpHash* after encryption. Because audit also uses *cpHash* and *rpHash*, audit of an encrypted session, although valid, is unlikely to be useful at the application level.

A response may have parameters only if the *responseCode* is TPM_RC_SUCCESS.

The architectural limit for the number of parameters in the handle area is 15. This limit is determined by the error-reporting scheme.

NOTE 2 This is the limit of parameters in the parameter list, not the number of values that may be in the parameter area. If a command needs more than 15 parameters, a new structure may be defined that encapsulates two or more of those parameters into a single structure, which may then be unmarshaled as a unit. The only loss is that error reporting may not provide as much detail when a compound parameter has an error.

As described in clause 21, for a command or response parameter to be encrypted, it must be the first parameter and it must be a TPM2B type.

NOTE 3 In order to encrypt more than one parameter, they must be encapsulated in a TPM2B making them a single parameter.

EXAMPLE The TPM2B_SENSITIVE_CREATE is the first parameter to TPM2_CreatePrimary(). The data member, TPMS_SENSITIVE_CREATE, has two members, a TPM2B_AUTH and a TPM2B_SENSITIVE_DATA. The encapsulation of them in the TPM2B_SENSITIVE_CREATE permits both to be encrypted.

18.5 *authorizationSize*/*parameterSize*

These values are only present if the tag of the command/response is TPM_ST_SESSIONS.

In a command, the *authorizationSize* indicates the number of octets in all of the authorization structures in the Authorization Area of the command. *authorizationSize* does not include the four octets of the *authorizationSize* value. The minimum value for *authorizationSize* is 9.

 Copyright © TCG 2006-2020

NOTE 1 The maximum value depends on the size of the largest digest produced by any hash implemented on the TPM.

NOTE 2 The driver and the TPM use the *authorizationSize* field to determine the number of authorizations. After *authorizationSize* bytes have been processed, there are no more authorizations.

In a response, *parameterSize* indicates the number of octets in the parameter area of the response and does not include the four octets of the *parameterSize* value. *parameterSize* may have a value of zero.

authorizationSize is not included in *cpHash*, and *parameterSize* is not included in the *rpHash*.

18.6 Authorization Area

18.6.1 Introduction

The Authorization Area is present in a command only if *tag* for the command is TPM_ST_SESSIONS. If present, the Authorization Area will contain:

- zero, one, or two authorizations (session or password);
- an optional session used for decrypting data sent to the TPM;
- an optional session used for encrypting data sent by the TPM; or
- an optional session used for auditing.

If *tag* is TPM_ST_SESSIONS, then the Authorization Area will have at least one but no more than three authorization/session blocks. If tag is TPM_ST_NO_SESSIONS, then there is no Authorization Area.

The number of authorization sessions that a command will have is indicated in the command schematic in TPM 2.0 Part 3. If a handle in the handle area has the "@" decoration, then an authorization session is required be present (an authorization session being either a password, a policy session, or an HMAC session).

The authorization sessions occur in the order of the associated entity handles. That is, the first handle with an "@" decoration will be associated with the first session in the Authorization Area.

Other sessions may be added to the Authorization Area. Those sessions may be designated as being for encryption, decryption, or audit; in any combination, in any order. However, in a single command, only one session is allowed to have the *encrypt* attribute, one session is allowed to have the *decrypt* attribute, and one session is allowed to have the *audit* attribute.

A single session may be used for authorization, encryption, decryption, and audit at the same time. That is, if a session has one handle with the "@" decoration, the associated authorization session may have the *encrypt*, *decrypt*, and *audit* attributes all set. A password authorization may not be used for anything but authorization and the TPM will return an error (TPM_RC_ATTRIBUTES) if *encrypt*, *decrypt*, or *audit* is SET in a password authorization.

NOTE 1 If an authorization session has *encrypt*, *decrypt*, and *audit* all SET, then the command can only have one authorization session.

The combinations of attributes allowed for each session are summarized in Table 6.

Table 6 — Use of Authorization/Session Blocks

Position	password authorization(1)(6)	authorization session(2)(6)	encryption session(3)	decryption session(4)	audit session(5)
1	✓	✓	✓	✓	✓
2	✓	✓	✓	✓	✓
3			✓	✓	✓

NOTES:

1) a password authorization may not be used for encryption, decryption, or audit.
2) an HMAC authorization session may also be used for encryption, decryption, and audit and a policy authorization session may also be used for encryption and decryption
3) only one session may be designated as being used for encryption
4) only one session may be designated as being used for decryption
5) password authorization sessions and policy sessions may not be used for audit
6) authorization sessions come before sessions used only for encryption, decryption, or audit

In TPM 2.0 Part 3, the schematic for each command will indicate if it has handles and if use of those handles requires authorizations. If there is an *at* symbol ("@") character in front of the handle name, then use of the TPM resource associated with the handle requires authorization and an authorization (session or password) will be present. An authorization will be present for each TPM resource that requires authorization (each handle with an "@"). An additional indication that a handle requires authorization is that, in the "Description" column of the command schematic, each handle has an "Auth Index:" entry. If that entry says "None", then no authorization is required. If that entry is followed by a number, then the number indicates the order of the associated authorization in the list of authorizations.

NOTE 2 Currently, no command requires more than two authorizations.

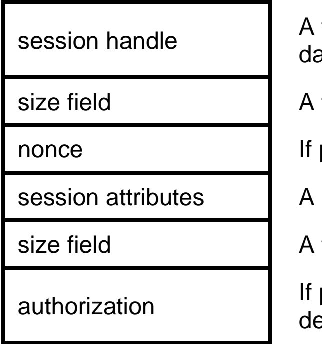
If a command requires authorizations, then those authorizations will be first in the list of authorizations/sessions. They may then be followed by other sessions used for encryption, decryption, or audit.

If the *responseCode* is TPM_RC_SUCCESS, the response has the same number of sessions in the same order as the request. Otherwise, no authorization or audit sessions are present.

18.6.2 Authorization Structure

18.6.2.1 Command

In a command, each authorization structure has the format shown in Figure 13.



A four-octet value indicating the session handle associated with this data block (will be TPM_RS_PW for a password authorization)

A two-octet value indicating the number of octets in *nonce*

If present, an octet array that contains a number chosen by the caller

A single octet with bit fields that indicate session usage

A two-octet value indicating the number of octets in *authorization*

If present, an octet array that contains either an HMAC or a password, depending on the session type

Figure 13 — Authorization Layout for Command

18.6.2.2 Response

In a response, each session structure has the format shown in Figure 14.

size field	A two-octet value indicating the number of octets in *nonce* (will be zero for a password authorization)
nonce	If present, an octet array that contains a number chosen by the TPM
session attributes	A single octet with bit fields that indicate session usage
size field	A two-octet value indicating the number of octets in *acknowledgment*
acknowledgment	If present, an octet array that contains an HMAC

Figure 14 — Authorization Layout for Response

Clause 19.6.7 describes the methods for creating an authorization session.

18.6.3 Session Handles

Session handles are described in 15.4. They identify the session being referenced by a specific session structure.

For a given command, the handle associated with a specific HMAC or policy session may occur only once in the Authorization Area. The handle representing a password authorization (TPM_RS_PW) can occur multiple times.

18.6.4 Session Attributes (*sessionAttributes*)

Each session has a *sessionAttributes* octet to indicate how the session is to be applied. Table 7 explains the meaning of the fields in this octet.

If a session is not being used for authorization, at least one of decrypt, encrypt, or audit must be SET.

Table 7 — Description of *sessionAttributes*

Attribute	Meaning
continueSession	This attribute is used to indicate to the TPM if the session is to remain 'active' when the command completes. If this attribute is CLEAR in the command and the command completes successfully (TPM_RC_SUCCESS), then the session will be flushed from TPM memory and the associated session handle will be available to be assigned to new sessions. When the TPM responds, it will echo this attribute to indicate that the session remains open (see the exception for password authorization below). NOTE In this context, "echo" means that the value of a session attribute will be the same in the response as it was in the command. The primary purpose of this attribute is to eliminate having to do explicit flushes (TPM2_FlushContext()) of a session when it is no longer used. Having this bit CLEAR on the last use of the session will end it and reclaim the TPM resources assigned to this session. For a password authorization, this attribute has no effect, as there are no TPM resources associated with a password authorization. This attribute will always be SET in a response associated with a password authorization. If the audit attribute is SET, then this attribute should also be SET since the audit data will be lost if the session is flushed.

 Copyright © TCG 2006-2020

Attribute	Meaning
decrypt	This attribute is used to indicate to the TPM that the secrets associated with the session are to be used to decrypt the first parameter of the command (the session-based encryption scheme is defined in clause 21). The parameter will be decrypted after the HMAC computations are successfully completed. This attribute may only be SET in a command that has a sized buffer as its first parameter. This attribute is required to be CLEAR in a password session. If SET in a password session, then the TPM will return an error because there is no session key for the decrypt operation This attribute is echoed by the TPM in the corresponding session in the response This attribute may only be SET in one session per command. A session with this attribute does not need to be associated with an entity identified in the handle area. That is, the session may be added just for using the session's secret for parameter decryption. This attribute can be SET in combination with any other session attribute.
encrypt	This attribute is used to indicate to the TPM that the secrets associated with the session are to be used to encrypt the first parameter of the response (the session-based encryption scheme is defined in clause 21). The parameter will be encrypted before the TPM performs the HMAC computations for any of the sessions. This attribute may only be SET in a response that has a sized buffer as its first parameter. This attribute is required to be CLEAR in a password session. If SET in a password session, then the TPM will return an error because there is no session key for the encrypt operation. This attribute is echoed by the TPM in the corresponding session in the response. This attribute may only be SET in one session per command. A session with this attribute does not need to be associated with an entity identified in the handle area. That is, the session may be added just for using the session's secret for parameter decryption. This attribute can be SET in combination with any other session attribute.
audit	This attribute indicates that the session is being used for audit. A digest is maintained in the session context and is updated each time the session is used with a command and *audit* is SET. This attribute does not need to be SET in every use of the session but the TPM will only update the audit data when the session is used with this attribute SET. This attribute has no meaning for a password authorization and is required to be CLEAR. This attribute is not allowed to be SET in a policy or trial policy session. This is because the context of the policy session would have to increase in order to hold the additional audit digest. This is significant overhead and, rather than require the additional memory in policy sessions, use of audit is restricted to HMAC sessions. After an HMAC session is started (TPM2_StartAuthSession(*sessionType* = TPM_SE_HMAC), this attribute may be set in any subsequent use of the session. On the first use of the session with this attribute set, the TPM will initialize the audit digest to 0…0 and then extend the concatenation of cpHash for the command and rpHash for the response. This attribute will be echoed by the TPM in the response. This attribute may be used in combination with any other session attributes but only one session in each command may have this attribute SET.

Attribute	Meaning
auditExclusive	This attribute is used to restrict use of an audit session. When this attribute is SET, the TPM will validate that the session has been used for all auditable commands since the audit sequence was started. NOTE An audit sequence is started when the audit digest is reset to 0…0. The audit digest is set to 0…0 when the session is first used as an audit session and when the audit digest is reset (see the description of the *auditReset* attribute below). If the session was used for all auditable commands, then it is said to be "exclusive"(see 20.2 for explanation of exclusive audit sessions). If this attribute is SET and the session is exclusive, then the command will execute. Otherwise, the TPM will fail this command to indicate to the caller that some TPM actions were not included in the audit sequence. Evaluation of the exclusive status is done at the start of the command. A session does not obtain the exclusive status until the end of the command (this prevents a session from becoming exclusive if the command fails). The implication of this processing is that, if this attribute is SET in the command that starts the audit sequence, the command will fail because the session has not yet become exclusive. In a response, this attribute will be SET if the session has exclusive status. When a session is first used as an audit session this attribute will be SET in the response as no command has executed without this session since the start of the sequence. This attribute may only be SET when the *audit* attribute is SET which excludes this attribute from being SET on a password authorization or a policy session.
auditReset	This attribute allows the caller to restart an audit sequence with a session that has previously been used for audit. If the associated command completes successfully, the TPM will initialize the session audit hash with 0…0 before Extending the cpHash and the rpHash. The response will have the exclusive attribute SET. This attribute may only be SET if audit is SET. The TPM will echo this attribute in the response.

18.7 Command Parameter Hash (*cpHash*)

The command parameter hash (*cpHash*) is used in the computation of a command authorization HMAC and is included in the digests of session and command audits (depending on the policy, the *cpHash* may also be used in the authorization). The *cpHash* is computed from the parameters of the command as follows:

$$cpHash \coloneqq \mathbf{H}_{sessionAlg}(commandCode \; \{|| \; Name1 \; \{|| \; Name2 \; \{|| \; Name3 \;\}\}\} \; \{|| \; parameters \;\}) \qquad (15)$$

where

$\mathbf{H}_{sessionAlg}$ hash function using the algorithm selected for the session when it was initialized

$commandCode$ command code for the command

$Name1$ unique identity of the entity associated with the first handle

$Name2$ unique identity of the entity associated with the second handle

$Name3$ unique identity of the entity associated with the third handle

 Copyright © TCG 2006-2020

$parameters$	remaining command parameters

18.8 Response Parameter Hash (*rpHash*)

The response parameter hash is used in the computation of a response acknowledgment HMAC and is included in the digest of session and command audits. The *rpHash* is computed from the parameters of the response as follows:

$$rpHash \coloneqq \mathbf{H}_{sessionAlg}(responseCode \mid\mid commandCode \{\mid\mid parameters\}) \quad (16)$$

where

$\mathbf{H}_{sessionAlg}$	hash function using the algorithm selected for the session when it was initialized
$responseCode$	command result code
$commandCode$	the commandCode from the command
$parameters$	response parameters

The contents of the *handles* area of the response are not included in the *rpHash*.

NOTE An *rpHash* needs to be computed only when the *responseCode* is TPM_SUCCESS, which means that it is redundant to include the response code. It is retained for legacy reasons.

18.9 Command Example

Table 8 shows an example of a command schematic used in this specification. The command has two object handles (*handleA* and *handleB*). The "@" on the handleA name indicates that use of the entity associated with the handle requires authorization. The command has at least one session to authorize use of *handleA*. It will not have a session for use of *handleB*. The Authorization Area may have an additional audit session and a session used only for parameter encryption. Since one session is required, *tag* is TPM_ST_SESSIONS, and the *authorizationSize* field is present.

Although they are not shown in the command schematic, the *authorizationSize* value and the Authorization Area would be present in the command buffer and be located between *handleB* and *dataSize*.

NOTE: The Authorization Area is not shown with the command schematic because no single representation is possible.

The command and response tables have three columns.

1) **Type** – This column indicates the data type of the parameter passed to the TPM in a command or received from the TPM in a response.
2) **Name** – This column indicates the name of the parameter. This name is referenced in the description of the command that precedes the command table and in the detailed actions of the command that follows the response table.

 Copyright © TCG 2006-2020

3) **Description** – This column provides a limited description of the parameter and indicates the possible options for the command.

EXAMPLE 1

Table 8 — Command Layout for Example Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Example
TPM_HANDLE	@handleA	handle to use for one object of the command Auth Index: 1 Auth Role: USER
TPM_HANDLE	handleB	handle to use for the second object Auth Index: None
UINT32	dataSize	example data size
OCTET	data[dataSize]	example data

Table 9 illustrates all command octets for the command in Table 8. In this example, the nonce size is 20 octets and the authorization HMAC is computed using SHA256. The values in shaded cells are not shown in the TPM 2.0 Part 3 schematic of the command but are included in the command data sent to the TPM.

EXAMPLE 2

Table 9 — Example Command Showing *authorizationSize*

Offset	Size	Parameter	Value
0	2	tag	TPM_ST_SESSIONS
2	4	commandSize	**209** < size in octets of the command >
6	4	commandCode	TPM_CC_Example
10	4	handleA	< a valid TPM resource handle>
14	4	handleB	< a valid TPM resource handle>
18	4	authorizationSize	**61** < size of the authorization session >
22	4	authHandle	< a valid TPMI_SH_AUTH_SESSION >
26	2	nonceCallerSize	**20** < size of *nonce* >
28	20	nonceCaller	< a 20-octet random value>
48	1	sessionAttributes	(continueSession=1)
49	2	hmacSize	**32** <size of *HMAC*>
51	32	HMAC	< a 32-octet HMAC value based on SHA256>
83	2	dataSize	**32** < size of the buffer >
85	124	data[dataSize]	< 124 octet buffer >
209

18.10 Response Example

Table 10 shows an example schematic as it would appear in TPM 2.0 Part 3. The example is for a response sent from the TPM after successful completion of the example command in Table 8. The response has the same number of sessions in the same order as did the command.

EXAMPLE 1

Table 10 — Response Layout for Example Command

Type	Name	Description
TPM_ST	tag	TPM_ST_SESSIONS
UINT32	responseSize	
TPM_RC	responseCode	response code of the operation
TPM_HANDLE	handle	not included in the rpHash
UINT32	dataSize	size in octets of the following data
OCTET	data[dataSize]	a returned block of information

Table 11 illustrates the full response for the command in Table 8. As in the command, the nonce size is 20 octets and the acknowledgment HMAC is computed using SHA256. The values in shaded cells are not shown in the TPM 2.0 Part 3 schematic of the response but are present in the response data from the TPM.

EXAMPLE 2

Table 11 — Example Response Showing *parameterSize*

Offset	Size	Parameter	Value
0	2	tag	TPM_ST_SESSIONS
2	4	responseSize	**203** < size in octets of the response >
6	4	responseCode	**0** < success >
10	4	handle	< a valid TPM_HANDLE >
14	4	parameterSize	**128**
18	4	dataSize	**124**
22	124	data[dataSize]	< 124 octet buffer >
146	2	nonceTpmSize	**20**
148	20	nonceTPM	< a 20-octet random value >
168	1	sessionAttributes	(continueSession=1)
169	2	hmacSize	**32**
171	32	HMAC	< a 32-octet HMAC value based on SHA256 >

19 Authorizations and Acknowledgments

19.1 Introduction

Many commands to the TPM reference TPM-resident structures and use of these structures may require authorization. This authorization is provided in structured data that follows the command data. When an authorization is provided to a TPM, the TPM will provide an acknowledgment.

To provide flexibility in how the authorizations are given to the TPM, this specification defines three authorization types:

1) password;

2) HMAC; and

3) policy.

Depending on the command, zero, one, or two authorizations may be required. In a command, the authorizations follow the handles, and in a response, the authorization replies follow the response parameters. The command definition indicates how many authorizations are required.

19.2 Authorization Roles

For each object and NV Index, there is a set of operations that can be performed on or with that object or NV Index. The operations are divided into groups, based on the impact of the operation on the object. To perform an operation with or on an object in a group, the authorization specific to that group must be provided. When performing an operation in one of the groups, the caller is acting in a specific role with respect to that object.

The TPM supports three different authorization roles. The role and attributes determine whether a password or HMAC can be used for authorization. A policy (if not the Empty Policy) can always be used.

1) **USER** – this authorization role is used for the normal uses of a key (e.g., signing with a signing key, or loading the child of a Storage Key). Methods are defined to allow USER role authorization to be provided either with an authorization value (*authValue*) or a policy. If *userWithAuth* is SET, then USER role authorization may be provided with a password authorization or an HMAC session. If *userWithAuth* is CLEAR, then a password and HMAC authorizations may not be used to provide USER role authorizations. A policy session that satisfies the *authPolicy* of the entity may be used regardless of the setting of *userWithAuth*.

NOTE 1 For USER role, an *authPolicy* is satisfied when the *policyDigest* of a policy session matches the value of the *authPolicy* value of the object.

NOTE 2 If use of an object is to be gated based on PCR values, a policy session is required (see 19.7). If the intent is that different Users have access to the object but only if the PCR are correct, then it is likely that authorization with the *authValue* will be disabled; otherwise, the caller could circumvent PCR protections simply by providing the *authValue*.

2) **ADMIN** – the object Administrator controls the certification of an object (TPM2_Certify() and TPM2_ActivateCredential()) and controls changing of the *authValue* of an object (TPM2_ObjectChangeAuth()). When an action requires ADMIN role authorization, that authorization may be provided using the *authValue* of the object if the *adminWithPolicy* attribute of the object is CLEAR. As with USER role authorization, ADMIN role may always be provided with a policy session as long as the policy session satisfies the *authPolicy* of the object.

NOTE 3 For ADMIN role, an *authPolicy* is satisfied when *policySession→policyDigest* matches the value of the *authPolicy* value of the object and *policySession→commandCode* matches *commandCode* for the authorized command.

EXAMPLE If the *adminWithPolicy* attribute of an object is SET, and if no branch in the object's policy equation contains TPM2_PolicyCommandCode(TPM_CC_Certify), then certification of that key may not occur.

3) **DUP** – this authorization role is only used for TPM2_Duplicate(). If duplication is allowed, authorization must always be provided by a policy session and the *authPolicy* equation of the object must contain a command that sets the policy command code to TPM_CC_Duplicate.

19.3 Physical Presence Authorization

Authorization for some commands requires that it be provided with Platform Authorization. Authorization for some other commands allows use of either Platform Authorization or Owner Authorization (Most of these commands cause persistent state change of the TPM). For these commands, it is possible to require that authorization be augmented with an out-of-band method.

For commands that require Platform Authorization and commands that require a hierarchy authorization, it is possible to require an out-of-band authorization. This may take any number of forms, such as a dedicated pin in the TPM, a special signaling method through the TPM interface, or any desired alternative. Whatever the form, the out-of-band authorization is referred to in this specification as Physical Presence (PP). This does not mean that the signaling requires a human to be physically present in order for the indication to be provided. The term is used in this specification because it was used in previous TPM specifications to refer to a similar concept.

The TPM maintains a table of the commands that require that PP be asserted to authorize command execution. Only certain commands may be included in this table. If, in TPM 2.0 Part 3, the schematic for a command has TPM_RH_PLATFORM in the "Description" column for one of the handles, then that command can be added to the list of commands that require PP. Otherwise, it may not.

NOTE 1 In the "Description" column, TPM_RH_PLATFORM will be followed by +PP if assertion of Physical Presence is required or "+{PP}" to indicate that assertion of Physical Presence may be required if indicated by the table.

NOTE 2 A platform-specific specification may require that the table be initialized in a specific way. It could even require that the table have certain commands defined to require PP confirmation even though a PP interface is not provided on the TPM. This would serve to disable the use of that command by the platform.

When the authorization handle is TPM_RH_PLATFORM, the TPM checks the table to see if the command requires confirmation with PP. If so, PP is checked before the TPM performs any other authorization checks.

TPM2_PP_Commands() is used to change the contents of the table of commands that require confirmation with PP authorization. Authorization of the command TPM2_PP_Commands() requires that PP be asserted and TPM2_PP_Commands() may not be removed from the list of commands that require PP.

NOTE 3 This constraint on TPM2_PP_Commands() prevents setting or modification of the table if no PP interface exists on the TPM.

The contents of the table may be read using TPM2_GetCapability(*capability* == TPM_CAP_PP_COMMANDS).

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

19.4 Password Authorizations

A plaintext password value may be used to authorize an action when use of an *authValue* is allowed. A plaintext password may be appropriate for cases in which the path between the caller and the TPM is trusted or when the authorization value is well known. For these instances, encryption of parameters or the hiding of authorization values in an HMAC is not required.

NOTE 1 While it may seem relatively easy for a caller to perform an HMAC, there are situations where the caller is resource-constrained and unable to do so. This is especially true when the calling software does not support the hash algorithms implemented in the TPM. Additionally, authentication using a cryptographic protocol makes it difficult to provide operating system abstractions.

A reserved authorization handle (TPM_RS_PW) indicates that the authorization is a password.

TPM_RS_PW is always available, and a separate action to create an authorization session is not required. A password authorization does not use nonces. *sessionAttributes→continueSession* is ignored.

A password authorization lets the caller send more or fewer octets than are present in the object's authorization field. The TPM truncates any octets of zero on either of the two values before they are compared.

If present, a password authorization is always associated with a command handle that requires authorization as there is no session context associated with a password that would allow it to be used for encryption or command audit.

Unlike other handles for other session types, the TPM_RS_PW session handle may be used for more than one authorization.

Password authorization data sent to the TPM has the format shown in Table 12.

Table 12 — Password Authorization of Command

Type	Name	Description
TPMI_SH_AUTH_SESSION	authHandle	required to be the reserved authorization session handle TPM_RS_PW
TPM2B_NONCE	nonceCaller	required to be an Empty Buffer
TPMA_SESSION	sessionAttributes	only *continueSession* may be SET
TPM2B_AUTH	password	authorization compared to the *authValue* of the TPM entity

Table 13 illustrates the format of a password authorization in a response. This structure is provided to ensure a one-to-one correspondence between the sessions in the command and in the response.

Table 13 — Password Acknowledgment in Response

Type	Name	Description
TPM2B_NONCE	nonceTPM	zero-length for a password authorization
TPMA_SESSION	sessionAttributes	copy of the flags from the password authorization in the command, *continueSession* will be SET
TPM2B_AUTH	hmac	zero-length buffer for a password authorization

NOTE 2 This structure is used to provide symmetry between password and other response sessions.

 Copyright © TCG 2006-2020

19.5 Sessions

A session is a collection of TPM state that changes after each use of that session. When an object context is loaded into the TPM, multiple copies of the object context may exist both on the TPM and in saved contexts (see clause 30). When a session context is created, only one copy of that context may exist, either on the TPM or as a saved context. The context of a session changes on each use.

A session has a handle that is assigned by the TPM when the session is created. That handle will always refer to the same session until the session is closed. If a handle is re-assigned to a subsequently created session, the session context data will contain a TPM-generated nonce that makes the new instance of the session unique, even though the handle may have been used previously. This nonce will change each time the session is used so that previous instances of the same session can be distinguished from each other (i.e., the nonce prevents reuse of stale session contexts).

There are three uses of a session:

1) **authorization** – A session associated with a handle is used to authorize use of an object associated with a handle. If it is not a password authorization, it may also be used to provide keys for encryption of command or response parameters. A policy session used to authorize may not also be used as an audit session. An HMAC session used to authorize may be used as an audit session.
2) **audit** – An audit session collects a digest of command/response parameters to provide proof that a certain sequence of events occurred. An audit session may also be used to provide secrets for encryption of command or response parameters and may be used for authorization of an HMAC session.
3) **encryption** – A session that is not used for authorization or audit may be present for the purpose of encrypting command or response parameters. If an encryption-only session exists, it will follow the authorization sessions and may come before or after a session used only for audit.

A command may have as many as three authorization blocks. Password blocks may only be used for authorization, so the maximum number of password blocks is equal to the number of authorizations required by the command.

19.6 Session-Based Authorizations

19.6.1 Introduction

Session-based authorizations are used both for protocols that require confidentiality for the authorization value and for audit sessions that require tracking of a sequence of commands sent to the TPM. An authorization session also provides a means of linking the uses of the session.

There are two types of session-based authorization: HMAC and policy. Both types of session are initiated using TPM2_StartAuthSession(). That command establishes the parameters that will be used for the authorizations. The *sessionType* parameter determines if the session will be an HMAC or policy session. When the session is started, the hash algorithm and TPM nonce size used in the session are specified by the caller. The command may include an initial caller nonce and a *salt* value to generate the session key. The parameters of each session are independent from the parameters of any other session and are limited only by the capabilities of the TPM. When TPM2_StartAuthSession() completes successfully, the TPM returns a handle for the session as well as the initial *nonceTPM* value.

Once an authorization session is established, it may be used to authorize actions in multiple commands. The session is not ended until explicitly closed or flushed.

The secret values of a session are determined by the handles used when the session is started. The command for starting a session allows selection of up to two object handles. One handle indicates a TPM

object that is used to encrypt a salt value that is sent when the session is started. A second handle indicates an object containing a shared secret. The salt value and the shared secret are combined with a nonce provided by the caller to create the session secrets.

NOTE Using the endorsement key for which the certificate chain has been validated as the salt key can ensure that the caller is connected to an authentic TPM.

19.6.2 Authorization Session Formats

For a session-based authorization session, the authorization structure for a command is as shown in Table 14.

Table 14 — Session-Based Authorization of Command

Type	Name	Description
TPMI_SH_AUTH_SESSION	authHandle	the handle for the authorization session
TPM2B_NONCE	nonceCaller	the caller-provided session nonce; size may be zero
TPMA_SESSION	sessionAttributes	the flags associated with the session
TPM2B_AUTH	hmac	the session HMAC digest value

In a response, the format for the acknowledgement is as shown in Table 15.

Table 15 — Session-Based Acknowledgment in Response

Type	Name	Description
TPM2B_NONCE	nonceTPM	the TPM-provided session nonce. Size is as specified when the session was started.
TPMA_SESSION	sessionAttributes	the flags associated with the session. This attribute should be the same as the values in the command except *continueSession* may be CLEAR.
TPM2B_AUTH	hmac	the session HMAC digest value

19.6.3 Session Nonces

19.6.3.1 Overview

The primary use of a nonce in a session is to prevent an authorization from being reused. When the session is started by TPM2_StartAuthSession(), the caller indicates, among other things, the size of the nonces to be used in the authorization HMAC and an initial nonce value (*nonceCaller*). After establishing the session, the TPM returns a handle to identify the session and a TPM-generated random nonce (*nonceTPM*). The TPM stores this *nonceTPM* in the context of the session.

Each time the session is used for authorization, the caller performs an HMAC using, along with other parameters, the last *nonceTPM* for the session and a new *nonceCaller* for the session. The TPM then uses the received *nonceCaller* and the saved *nonceTPM* to validate the HMAC. For a response, the TPM uses the last *nonceCaller* and a newly generated *nonceTPM* in the HMAC. The caller then uses the received *nonceTPM* and the saved *nonceCaller* to validate the HMAC in the response.

A nonce has a size field indicating the number of octets in the nonce followed by the nonce data. The nonce size is not included in the HMAC computation.

 Copyright © TCG 2006-2020

19.6.3.2 Session Nonce Size

When an authorization session is created, the caller provides an initial nonce (*nonceCaller*). The size field of *nonceCaller* is retained by the TPM and used to determine the size of all nonces generated by the TPM (*nonceTPM*) in the subsequent uses of the session. The minimum size for *nonceCaller* in TPM2_StartAuthSession() is 16 octets.

After the initial session setup, the caller may use any size for a *nonceCaller* in each use of the session. The *nonceCaller* size may vary from zero (0) up to the size of *nonceTPM* (the initial *nonceCaller* size).

NOTE A TPM implementation may allow larger nonce sizes but the caller should not expect a TPM to accept a nonce size larger than the initial *nonceCaller* size.

The maximum size that may be requested for *nonceTPM* is the size of the digest produced by the authorization session hash.

EXAMPLE For SHA-1 the maximum size for *nonceTPM* is 20 octets and for SHA256 it is 32 octets.

When a session nonce is used in the authorization session HMAC, the *size* field of the nonce is not included in the authorization computation. If the nonce *size* field is zero (0), then the nonce does not affect the authorization HMAC value.

19.6.3.3 Guidance on Nonce Size Selection

The size of the nonce should be chosen to provide a reasonable guarantee that a TPM-generated nonce value will not be used twice with the same *sessionKey*. The choice of nonce size is not related to the number of uses of a specific authorization session but is related to the number of uses of the *sessionKey*.

An HMAC *sessionKey* is derived from the *authValue* kept in an object and that *authValue* may have a long lifetime. To prevent replay attacks on a long-lived *authValue,* use of large nonces is recommended.

NOTE 1 The combined *nonceCaller* plus *nonceTPM* are what determine the anti-replay protection provided by the nonces. Making the combined size larger than the block size of the session hash is not particularly useful. If the caller does not have a good source of entropy for an RNG, then making the *nonceTPM* the size of the digest of the session hash is recommended, so that a *nonceCaller* size of zero would be satisfactory.

NOTE 2 When using a session for encryption, if a parameter is encrypted in a response to one command and a parameter is encrypted in the request of the next command, and they both use the same session for encryption, then the caller should provide a *nonceCaller* in order to prevent the use of the same encryption key on the input and output. A nonce of length 1 with a value of zero would suffice.

19.6.3.4 Nonce Binding

A command may have sessions other than those required for authorization. One use of an extra session is to encrypt a command or response parameter. If an extra encrypting session were removed by an attacker, the TPM would not properly encrypt/decrypt the data and could, as a result, fail to encrypt a response parameter. To prevent removal of extra encrypting sessions, the *nonceTPM* of each of these sessions is included in the HMAC computation of the first authorization session of a command. If an extra session is removed by an attacker, the first authorization will fail, and the command will not be executed.

To simplify the logic in the TPM, the *nonceTPM* of any session used for encryption of command or response data is included in the HMAC computation for the first session even if the encrypt or decrypt session is also an authorization session.

NOTE If the first session is a password authorization, then the path to the TPM is trusted and there is no need to guard against the extra session being removed, also there is probably no need for parameter encryption when a trusted path is present.

 Copyright © TCG 2006-2020

19.6.4 Authorization Values

19.6.4.1 Overview

An object may have a value used to authorize various actions on the object. An authorization session is the mechanism through which a caller proves knowledge of the authorization value (*authValue*) needed to allow an action.

An *authValue* may be sent as a password that does not provide confidentiality (see 19.4), or in an HMAC-based authorization session that can provide confidentiality of the *authValue*.

19.6.4.2 authValue Size

An *authValue* may be as small as zero octets but not larger than the digest size of the algorithm used to compute the Name of the object.

EXAMPLE If the Name algorithm for an object is SHA256, then the largest *authValue* for the object would be 32 octets.

19.6.4.3 Authorization Size Convention

When an *authValue* is based on a password or passphrase, then the *authValue* should be the password/phrase as long as the password/phrase is no larger than the digest produced by the *nameAlg* of the object.

EXAMPLE If the passphrase is “This is a sample passphrase”, and *nameAlg* is TPM_ALG_SHA256, then the *authValue* is 27 octets long containing the value “This is a sample passphrase”.

Trailing octets of zero are to be removed from any string before it is used as an *authValue*.

If the password/phrase, with trailing zeros removed, is longer than the digest produced by the *nameAlg* of the object, then the password/phrase – with trailing octets of zero removed – is hashed using *nameAlg* and the resulting hash given to the TPM as the *authValue* for the object.

19.6.5 HMAC Computation

The HMAC computation for all session types is the same. A *sessionKey* value is concatenated to an *authValue* to create the key that is used in the computation of the HMAC in a command or response. If *sesssionkey* and *authvalue* are both the Empty Buffer, see 19.6.15.

$$\begin{aligned} authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}(&(sessionKey \mathbin{||} authValue), \\ &(pHash \mathbin{||} nonceNewer \mathbin{||} nonceOlder \\ &\{ \mathbin{||} nonceTPM_{decrypt} \} \{ \mathbin{||} nonceTPM_{encrypt} \} \\ &\mathbin{||} sessionAttributes)) \end{aligned} \quad (17)$$

where

$\mathbf{HMAC}_{sessionAlg}$	the HMAC function using the hash algorithm specified when the session was started
$sessionKey$	a value that is computed in a protocol-dependent way, using **KDFa**(). When used in an HMAC or KDF, the size field for this value is not included.
$authValue$	a value that is found in the sensitive area of an entity. This value is an EmptyAuth if the HMAC is being computed to authorize an action on the

 Copyright © TCG 2006-2020

object to which the session is bound. The size field for this value is not included in any KDF or hash function.

NOTE 1 For policy sessions, the *authValue* is not included in the HMAC calculation unless the policy session included TPM2_PolicyAuthValue() and it was not superseded by TPM2_PolicyPassword().

NOTE 2 Trailing zeros are always removed from an *authValue* before it is used in an authorization computation.

$pHash$ digest of the command (cpHash) or response parameters (rpHash) using the session hash algorithm.

$nonceNewer$ a value that is generated by the entity using the session. A new nonce is generated on each use of the session. For a command, this will be nonceCaller and for a response, nonceTPM. The nonce size field is not included in the HMAC.

$nonceOlder$ a value that was received the previous time the session was used. For a command, this will be nonceTPM and for a response, nonceCaller. The nonce size field is not included in the HMAC.

$nonceTPM_{decrypt}$ in the HMAC computation for the first authorization session of a command, if a different session is being used for parameter decryption, then the nonceTPM for that session is included in the HMAC of the first authorization session; but only in the command (see 19.6.3.4). The nonce size field is not included in the HMAC.

NOTE 3 The *decrypt* session is used by the TPM to decrypt a parameter in the command.

NOTE 4 The nonce of the *decrypt* session is included even if that session is also used for authorization.

$nonceTPM_{encrypt}$ in the HMAC computation for the first authorization session of a command, if a different session is being used for parameter encryption, then the nonceTPM for that session is included in the HMAC of the first authorization session; but only in the command (see 19.6.3.4). The nonce size field is not included in the HMAC.

NOTE 5 The *encrypt* session is used by the TPM to encrypt a parameter in the response.

NOTE 6 The nonce of the *encrypt* session is included even if that session is also used for authorization.

NOTE 7 If the same session (not the first session) is used for decrypt and encrypt, its *nonceTPM* is only used once. If different sessions are used for decrypt and encrypt, both *nonceTPM*s are included.

$sessionAttributes$ an octet indicating the attributes associated with a particular use of the session

With the exception of $sessionAttributes$, all the values are large numbers, typically with sizes of 20 octets or more.

In the HMAC computation equations shown below, the possibility that the HMAC computation may include $nonceTPM_{decrypt}$ or $nonceTPM_{encrypt}$ is indicated by "$nonceOlder*$" (asterisk added).

 Copyright © TCG 2006-2020

19.6.6 Note on Use of Nonces in HMAC Computations

In equation (17), and the HMAC computation equations that follow, all of the nonce values are in TPM2B_NONCE data structures. In the HMAC computations, the nonce entries should all be read as if they had the *.buffer* suffix indicating that only the data portion of a nonce is ever used in an HMAC computation.

19.6.7 Starting an Authorization Session

TPM2_StartAuthSession() is used to start an authorization session. The parameters of this command may be chosen to produce sessions with different properties.

Table 16 — Schematic of TPM2_StartAuthSession Command

Type	Name	Description
TPM_ST	tag	
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT+	tpmKey	handle of a loaded key used to encrypt *salt* may be TPM_RH_NULL Auth Index: None
TPMI_DH_ENTITY+	bind	entity providing the *authValue* may be TPM_RH_NULL Auth Index: None
TPM2B_NONCE	nonceCaller	initial *nonceCaller,* sets nonce size for the session
TPM_SE	sessionType	indicates the type of session (HMAC or policy)
TPM2B_ENCRYPTED_SECRET	encryptedSalt	*tpmKey* algorithm-dependent secret if *tpmKey* is TPM_RH_NULL, this shall be an Empty Buffer
TPMT_SYM_DEF+	symmetric	the algorithm and key size for parameter encryption may select TPM_ALG_NULL
TPMI_ALG_HASH	authHash	hash algorithm to use for the session; and shall be a hash algorithm implemented on the TPM and not TPM_ALG_NULL

The two values that determine the session protection values are *tpmKey* and *bind*. Both of these handles can reference TPM_RH_NULL or a TPM entity. The *tpmKey* parameter references the key that is used to encrypt a salt value that is used in the computation of the *sessionKey*. The *bind* parameter references a TPM entity that may provide an *authValue* to the computation for the *sessionKey*. The four variations for *tpmKey* and *bind* give sessions with different properties.

 Copyright © TCG 2006-2020

Table 17 — Handle Parameters for TPM2_StartAuthSession

tpmKey	bind	session properties
TPM_RH_NULL	TPM_RH_NULL	Unbound session
TPM_RH_NULL	TPM entity	Bound session
TPM key	TPM_RH_NULL	Salted session
TPM key	TPM entity	Salted and bound session

19.6.8 *sessionKey* Creation

A *sessionKey* value is used in the HMAC computation as shown in equation (17). If both *tpmKey* and *bind* are TPM_RH_NULL, then *sessionKey* is set to an Empty Buffer. Otherwise, the *sessionKey* is created as follows:

$$sessionKey \coloneqq \mathbf{KDFa}(sessionAlg, (authValue \mathbin{||} salt), \text{“ATH”}, nonceTPM, nonceCaller, bits) \qquad (18)$$

where

$sessionAlg$	a TPM_ALG_ID for a hash that was chosen by the caller when the session was started
$authValue$	if *bind* is not TPM_RH_NULL, a TPM2B_AUTH.buffer that is found in the sensitive area of a TPM entity; otherwise, an Empty Buffer
$salt$	if *tpmKey* is not TPM_RH_NULL, then the salt value recovered from *encryptedSalt*; otherwise, an Empty Buffer
“ATH”	a four-octet label value (see 4.1)
$nonceTPM$	a TPM2B_NONCE that is generated by the TPM when the session was started
$nonceCaller$	a TPM2B_NONCE that is provided by the caller when the session was started.
$bits$	the number of bits returned is the size of the digest produced by *sessionAlg*

NOTE When an authorization failure occurs, the TPM will check to see if the use of the object is exempt from dictionary attack protection. If it is exempt, the response code is changed from TPM_RC_AUTH_FAIL to TPM_RC_BAD_AUTH and no increment of the failed authorization counter occurs (see 19.8).

19.6.9 Unbound and Unsalted Session Key Generation

In this session key generation method used by TPM2_StartAuthSession(), *tpmKey* and *bind* are both TPM_RH_NULL. This results in the session having no *sessionKey* (it is an Empty Buffer). The session is not bound to any object.

NOTE This session type is similar to the OIAP session of TPM 1.2.

A session started using this format can be used for parameter encryption while executing TPM commands. However, during these commands, the key used to encrypt the parameter will only use the *authValue* of the object being accessed by the commands in the key generation, so the strength of the encryption will be no better than the entropy in the *authValue* of the object.

When computing the HMAC, the *authValue* of the referenced entity is used:

 Copyright © TCG 2006-2020

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\,(authValue_{entity}.buffer,\ (pHash \,||\, nonceNewer.buffer \,||\, nonceOlder^{*}.buffer \,||\, sessionAttributes)) \quad (19)$$

If the size of *authValue* is zero, then the caller may omit the HMAC from the authorization (see No HMAC Authorization19.6.15).

Table 18 — Format to Start Unbounded, Unsalted Session

Type	Name	Description
TPM_ST	tag	
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT+	tpmKey	TPM_RH_NULL
TPMI_DH_ENTITY+	bind	TPM_RH_NULL
TPM2B_NONCE	nonceCaller	initial *nonceCaller,* sets *nonceTPM* size for the session
TPM2B_ENCRYPTED_SECRET	encryptedSalt	00 00_{16}
TPM_SE	sessionType	indicates the type of the session (HMAC, policy, or trial)
TPMT_SYM_DEF+	symmetric	will normally be TPM_ALG_NULL for an unbound and unsalted session
TPMI_ALG_HASH	authHash	hash algorithm to use for the session; required to be a hash algorithm implemented on the TPM and not TPM_ALG_NULL

NOTE When *sessionType* is TPM_SE_TRIAL, there is no benefit in using any other version of TPM2_StartAuthSession() as a trial session is not allowed to be used for authorization. This means that the *sessionKey* of the session will never be used so there is no point in having the TPM generate it.

19.6.10 Bound Session Key Generation

In this session key generation method used by TPM2_StartAuthSession(), *tpmKey* is TPM_RH_NULL indicating that no *salt* value is present but *bind* references some TPM entity with an *authValue*.

NOTE 1 This session type has properties that are similar to an OSAP session in TPM 1.2.

The *sessionKey* is computed using the *authValue* from *bind* and an Empty Buffer in place of the *salt* value.

$$sessionKey \coloneqq \mathbf{KDFa}\,(sessionAlg,\ authValue_{bind},\ \text{“ATH”},\ nonceTPM,\ nonceCaller,\ bits) \quad (20)$$

NOTE 2 If handle references a TPM resource that has an EmptyAuth, the *sessionKey* is still computed.

When performing an HMAC for authorization, the HMAC key is calculated as follows:

a) When the session is an HMAC session

1) If the authorization is not for the entity to which the session is bound, the HMAC key is the concatenation of the entity's *authValue* to the session's *sessionKey* (created at TPM2_StartAuthSession() (see equation (21).

 Copyright © TCG 2006-2020

2) If the authorization is for the entity to which the session is bound, the HMAC key is the session's *sessionKey* (created at TPM2_StartAuthSession() (see equation (22)).

b) When the session is a policy session

1) If the session has *isAuthValueNeeded* SET (by TPM_PolicyAuthValue()), the HMAC key is the concatenation of the entity's *authValue* to the session's *sessionKey* (see equation (21)).

2) If the session has *isAuthValueNeeded* CLEAR, the HMAC key is the session's *sessionKey* (created at TPM2_StartAuthSession() (see equation (22)).

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\,(sessionKey \,||\, authValue_{entity}),\ (pHash \,||\, nonceNewer \,||\, nonceOlder^{*} \,||\, sessionAttributes)) \tag{21}$$

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\,(sessionKey,\ (pHash \,||\, nonceNewer \,||\, nonceOlder^{*} \,||\, sessionAttributes)) \tag{22}$$

NOTE 3 Binding to an entity different from the one being authorized is a way of adding entropy to the session key. It is useful in cases where the entity being authorized has a low entropy authorization value.

The TPM is required to keep track of the entity to which the session is bound. This is nominally accomplished when the session is started by recording, in the session context, the Name of the *bind* entity. For an NV Index or persistent handle, the TPM is required to also record the authorization value associated with the entity.

NOTE 4 In the Part 4 reference implementation , the authorization value is combined with the Name and stored in the SESSION→boundEntity member.

NOTE 5 Recording of the NV Index authorization is required to prevent an attacker from "squatting" on an Index. This would be accomplished by creating an NV Index that has properties that are identical to an NV Index that is expected to be created, but with an authorization value known to the attacker. The attacker would then start an authorization session bound to the NV Index and delete the NV Index. When the NV Index to be attacked is created, the attacker would have an authorization session bound to an Index with the same Name and could access to the NV Index even though the actual authorization value is unknown.

On a command, the TPM will check to see if the authorization is being used for the entity to which it was bound. If so, then the *authValue* of the bound entity is not used in the HMAC computation. The TPM will record the fact that the *authValue* was not used in the HMAC computation of the authorization and not include it in the HMAC computation on the response.

NOTE 6 This allows the session to remain bound to an NV Index for the duration of the first command that writes to the Index even though the Name of the Index changes during the command processing. The session will not be bound to the Index when the command completes. The session can continue to be used, but it, in effect, is no longer bound because there is no longer a TPM entity with the correct Name.

For a persistent object, the authorization value is included so that authorization can be revoked. If the administrator for a persistent object changes the authorization, sessions bound to the old authorization should no longer be valid.

NOTE 7 To change the authorization of a persistent object, TPM2_ObjectChangeAuth() would be called. It would return a new sensitive area. The current persistent object would be deleted (TPM2_EvictControl()) and the object with the new authorization loaded (TPM2_Load()). Finally, the loaded object would be made persistent (TPM2_EvictControl()). It is only required that the old object be deleted if the new object is to have the same handle or if it is desired to revoke the old authorization.

 Copyright © TCG 2006-2020

The *noDA* attribute of the bind object is recorded in the session context. For a description of the rationale, see clause 19.8.7.

Table 19 — Format to Start Bound Session

Type	Name	Description
TPM_ST	tag	
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT+	tpmKey	TPM_RH_NULL
TPMI_DH_ENTITY	bind	entity providing the *authValue* to which the session is bound and not TPM_RH_NULL
TPM2B_NONCE	nonceCaller	initial *nonceCaller,* sets *nonceTPM* size for the session
TPM2B_ENCRYPTED_SECRET	encryptedSalt	00 00_{16}
TPM_SE	sessionType	indicates the type of the session (HMAC, policy, or trial)
TPMT_SYM_DEF+	symmetric	if the session is to be used for parameter encryption, set this to an algorithm and key size
TPMI_ALG_HASH	authHash	hash algorithm to use for the session; required to be a hash algorithm implemented on the TPM and not TPM_ALG_NULL

 Copyright © TCG 2006-2020

19.6.11 Salted Session Key Generation

In this session key generation method used by TPM2_StartAuthSession(), *bind* is TPM_RH_NULL, indicating that no entity is referenced to provide an *authValue,* but *tpmKey* is present and indicates a key used to encrypt the *salt* value. The *sessionKey* is computed with an Empty Buffer in place of the *authValue*.

$$sessionKey \coloneqq \mathbf{KDFa}\ (sessionAlg, salt, \text{“ATH”}, nonceTPM, nonceCaller, bits) \tag{23}$$

Because *bind* is TPM_RH_NULL, the session is not bound to any entity. When the session is used to access any entity, the HMAC will use the *sessionKey* and the *authValue* of that entity.

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\ ((sessionKey \mid\mid authValue_{entity}), (pHash \mid\mid nonceNewer \mid\mid nonceOlder^{*} \mid\mid sessionAttributes)) \tag{24}$$

Table 20 — Format to Start Salted Session

Type	Name	Description
TPM_ST	tag	
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT	tpmKey	handle of a loaded key used to encrypt *salt*
TPMI_DH_ENTITY+	bind	TPM_RH_NULL
TPM2B_NONCE	nonceCaller	initial *nonceCaller,* sets *nonceTPM* size for the session
TPM2B_ENCRYPTED_SECRET	encryptedSalt	conveys a secret value used to generate the *sessionKey* – method of conveying this value is dependent on the type of *tpmKey*
TPM_SE	sessionType	indicates the type of the session (HMAC, policy, or trial)
TPMT_SYM_DEF+	symmetric	if the session is to be used for parameter encryption, set this to an algorithm and key size
TPMI_ALG_HASH	authHash	hash algorithm to use for the session; required to be a hash algorithm implemented on the TPM and not TPM_ALG_NULL

 Copyright © TCG 2006-2020

19.6.12 Salted and Bound Session Key Generation

This version of TPM2_StartAuthSession() creates a session that has properties that are similar to the OSAP session type of TPM 1.2 but also allows salting. For this version of the command, *bind* is used to provide an *authValue*, *tpmKey* encrypts the *salt* value and the *sessionKey* is computed using both.

$$sessionKey \coloneqq \mathbf{KDFa}\ (sessionAlg, (authValuebind \mid\mid \text{salt}), \text{“ATH”}, nonceTPM, nonceCaller, bits) \quad (25)$$

If the session is an HMAC session:

- Because *bind* is present, the session is bound to that entity. That is, when the session is used to authorize use of the bound entity, the HMAC will use *sessionKey* but not the *authValue*.

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\ (sessionKey, (pHash \mid\mid nonceNewer \mid\mid nonceOlder^* \mid\mid sessionAttributes)) \quad (26)$$

If the session is a policy session:

- The session is not bound to that entity. That is, when the session is used to authorize use of any entity, the HMAC (if required) will use the *sessionKey* and the *authValue*.

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\ ((sessionKey \mid\mid authValue_{entity}), (pHash \mid\mid nonceNewer \mid\mid nonceOlder^* \mid\mid sessionAttributes)) \quad (27)$$

- The *noDA* attribute of the bind object is recorded in the session context. For a description of the rationale, see clause 19.8.7.

Table 21 — Format to Start Salted and Bound Session

Type	Name	Description
TPM_ST	tag	
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_StartAuthSession
TPMI_DH_OBJECT+	tpmKey	handle of a loaded key used to encrypt *salt*
TPMI_DH_ENTITY	bind	entity providing the *authValue* and to which the session is bound
TPM2B_NONCE	nonceCaller	initial *nonceCaller,* sets *nonceTPM* size for the session
TPM2B_ENCRYPTED_SECRET	encryptedSalt	contains a secret value used to generate the *sessionKey* – method of encrypting this value is dependent on the type of *tpmKey*
TPM_SE	sessionType	indicates the type of the session (HMAC, policy, or trial)
TPMT_SYM_DEF+	symmetric	if the session is to be used for parameter encryption, set this to an algorithm and key size
TPMI_ALG_HASH	authHash	hash algorithm to use for the session; required to be a hash algorithm implemented on the TPM and not TPM_ALG_NULL

19.6.13 Encryption of *salt*

19.6.13.1 Overview

The *salt* parameter for TPM2_StartAuthSession() is asymmetrically encrypted using the methods described in this clause.

The value produced by the secret exchange process using *salt* should be the size of the digest produced by the *authHash* of the session. For ECC, the size of the *seed* is limited because it is an ECC point; but for RSA, XOR, and AES, the size of *salt* may vary.

When the value of salt is determined, it is used in the computation of *sessionKey* as shown in equation (18).

19.6.13.2 Asymmetric Encryption of Salt

The methods of encrypting the salt and producing the session secret differ for each asymmetric algorithm. The methods are described in the algorithm-specific annexes to this specification.

19.6.14 Caution on use of Unsalted Authorization Sessions

If an *authValue* has low entropy, confidentiality of the value may not be preserved if the *authValue* is used in an unsalted authorization session. For an unbound, unsalted session, the HMAC computation for the response from the TPM is:

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\,(authValue,\ (rpHash \,||\, nonceTPM \,||\, nonceCaller \,||\, sessionAttributes)) \quad (28)$$

If an attacker can read the response from the TPM, then the only values unknown to the attacker are *authValue* and *nonceCaller*. An attacker may be able to determine *nonceCaller* by reading the command as it is sent to the TPM. If the attacker has all the variables but *authValue*, they could perform an "off-line" attack on the *authValue* using trial versions of *authValue* until one is found that produces a matching *authHMAC*.

NOTE 1 In this context, an "off-line" attack means that the attacker can perform computations that do not involve the TPM meaning that the protections that the TPM provides against authValue attacks has no effect.

It is important to note that this vulnerability only occurs if an attacker has access to both the command and response of a successful command using the *authValue*. If a user has a password protecting a key and the system is lost or stolen, the key is protected because the attacker will not be able to observe the legitimate owner of the key perform a successful operation with the key.

For a bound session without salt, the attack is a bit more complicated. The HMAC computation for the response is:

$$authHMAC \coloneqq \mathbf{HMAC}_{sessionAlg}\,((sessionKey \,||\, authValue_{entity}),\ (pHash \,||\, nonceNewer \,||\, nonceOlder \,||\, sessionAttributes)) \quad (29)$$

If the attacker observes a TPM2_StartAuthSession() command and response and the *authValue* for the bind entity has low entropy, then they would have all of the components of *sessionKey* except for the *authValue* of the *bind* entity. Then, by observing another successful transaction, an attacker could know everything but the two *authValues* and they could again perform an offline attack.

NOTE 2 If the successful operation is on the *bind* entity, then only one *authValue* is unknown.

 Copyright © TCG 2006-2020

As with the unbound and unsalted session, the vulnerability for a bound session only occurs if the attacker is able to observe successful command response sequences.

Salting provides a mechanism to allow use of low entropy *authValues* and still maintain confidentiality for the authValue. It is also possible to use a high entropy authValue to protect the confidentiality of a low-entropy value. For instance, if the *bind* entity *authValue* has high-entropy, then there would be greater computational complexity in guessing *sessionKey* || $authValue_{entity}$. Depending on the *authValue* and *salt* sizes, a bound session could have a *sessionKey* that is as difficult to guess as does a salted session.

19.6.15 No HMAC Authorization

For a session-based authorization, both HMAC and policy, an *authHMAC* value is computed as shown in equation (17) and that value is used as *hmac* in an authorization or acknowledgement as shown in Table 14 and Table 15 respectively. If an authorization session is started with *bind* and *tpmKey* both set to TPM_RH_NULL, then *sessionKey* in equation (17) will be an Empty Buffer. If the *authValue* in equation (17) is also an Empty Buffer, then the HMAC key will be an Empty Buffer. When this situation exists, the caller has the option of either providing the results of the *authHMAC* computation, or not.

If *authHMAC* is provided, it will be computed as shown in equation (17) with an Empty Buffer as the HMAC key and the TPM will validate that the value in *hmac* matches the internally calculated value.

If *authHMAC* is not provided, the size of *hmac* (see Table 14) will be zero and the TPM will accept this value of *hmac* as providing valid authorization for the object.

For an HMAC session, *authValue* in equation (17) will only be an Empty Buffer if the *authValue* of the authorized object is an EmptyAuth, the session is a bind session and the authorization is for the entity to which the session is bound, or if the session is not an authorization session.

For a policy session, two situations will result in *authValue* being an Empty Buffer:

1) the *authValue* of the authorized object is an EmptyAuth, or
2) the policy does not use the *authValue* of the object (that is, the evaluated policy does not contain TPM2_PolicyAuthValue())(see 19.7.7.6).

For these two cases, if *sessionKey* is an Empty Buffer, *hmac* is allowed to be either a valid *authHMAC* or an Empty Buffer. For a bound or salted policy session, *sessionKey* is not an Empty Buffer, and *hmac* must be valid.

NOTE A policy session that does not use TPM2_PolicyAuthValue() would use a bound or salted session if that session is also used for encryption.

For a policy session that contains TPM2_PolicyPassword(), the password takes precedence and must be present in *hmac*.

The TPM will use the same formulation in the response as was in the command. This is, if *hmac* was non-zero in the command, the TPM will compute *authHMAC* as shown in equation (17) and use the result as *hmac*. If *hmac* was an Empty Buffer in the command, it will be an Empty Buffer in the response.

19.6.16 Authorization Selection Logic for Objects

Each object has two attributes in its public structure to indicate how use of the object is authorized.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

1) ***userWithAuth*** – If this attribute is SET, then USER role authorization for an object may be provided with an HMAC session or a password. If this attribute is CLEAR, then the *authValue* may not be used for USER role authorization, meaning that authorization may not be done using an HMAC session or a password. USER role authorizations with a policy are always allowed regardless of the setting of this attribute.

2) ***adminWithPolicy*** – If this attribute is SET, then ADMIN role authorization for an object may only be provided with a policy session. If this attribute is CLEAR, then authorization may be provided with a policy session, with an HMAC session, or with a password.

When authorization is with a policy session and ADMIN role authorization is being provided, the command code value of the policy session must match the command code for the command being authorized.

For TPM_RH_OWNER, TPM_RH_ENDORSEMENT, and TPM_RH_PLATFORM); *userWithAuth* and *adminWithPolicy* are always SET.

For an NV Index, NV Index attributes (TPMA_NV) determine authorization selection.

NOTE For TPM_RH_OWNER, TPM_RH_ENDORSEMENT, and TPM_RH_PLATFORM); *userWithAuth* and *adminWithPolicy* do not have to be implemented as separate attributes. The code may simply assume that the attributes are SET and act accordingly.

19.6.17 Authorization Session Termination

The TPM will terminate a session (authorization or audit) and clear all associated context under the following circumstances:

- when TPM2_FlushContext() selects the session;
- if *sessionAttributes.continueSession* is CLEAR in the command, the TPM will CLEAR the continueSession flag in the response and perform TPM2_FlushContext() actions;

NOTE When *sessionAttributes.continueSession* is CLEAR in the command but the command does not return success, then the session is not terminated.

- on TPM Reset, all authorization sessions are terminated; and
- on TPM Resume or TPM Restart, authorization sessions in TPM memory will be terminated but sessions context saved off the TPM will remain active.

19.7 Enhanced Authorization

19.7.1 Introduction

Enhanced authorization is a TPM capability that allows entity-creators or administrators to require specific tests or actions to be performed before an action can be completed. The specific policy is encapsulated in a value called an *authPolicy* that is associated with an entity

When an HMAC session is used for authorization, the *authValue* of the entity is used to determine if the authorization is valid. When a policy session is used for authorization, the *authPolicy* of the entity is used.

Many TPM entities have or may have an associated *authPolicy*. A policy defines the conditions for use of an entity. For example,

- a policy may limit the use of a key unless selected PCR have specific values;
- a policy may not allow use of a key after a specific time;
- a policy may require that authorization to change an NV Index be provided by two different entities; or
- a policy may limit a particular signing key to attest to PCR values but not to certify another TPM key.

A policy may be arbitrarily complex. However, the policy is expressed as one (statistically unique) digest called the *authPolicy*.

The digest representing a particular policy may be included in an Object or NV Index when the Object or NV Index is created (the digest representing a policy is created using the methods described in subsequent parts of this clause). In order to use the Object or Index, a policy session is created and then the TPM is given a sequence of policy commands that modify the digest in the policy session. After executing all of the commands of the policy, the TPM will have computed a digest value that is characteristic of the policy. The policy session is then used as an authorization session. If the digest accumulated in the policy session matches the *policyDigest* of the entity (and certain other optional conditions are true) then the command is authorized.

After a policy session is used for authorization, *policySession→nonceTPM* is changed to a new, random value; *policySession→startTime* is set to the current time; and the other values of the policy session context are initialized to the state they had when the session was first created by TPM2_StartAuthSession() (see19.7.8).

The mechanisms of policy creation and evaluation are explained in the remainder of this clause

19.7.2 Policy Assertion

An assertion is a statement that something is true. In an authorization policy, an assertion is a statement of something that must be true before the policy is satisfied. For example, an assertion may be that a set of PCR must have specific values to allow an object to be authorized for use in a specific command. The list of all policy assertions defined by this specification is in 19.7.7.6.

A combination of one or more assertions is used to construct an authorization policy.

19.7.3 Policy AND

A policy may be expressed in an equation as a set of assertions that must all be satisfied before the policy is valid. For example, a policy that requires that 4 assertions be true could be written as:

$a \,\&\, b \,\&\, c \,\&\, d$

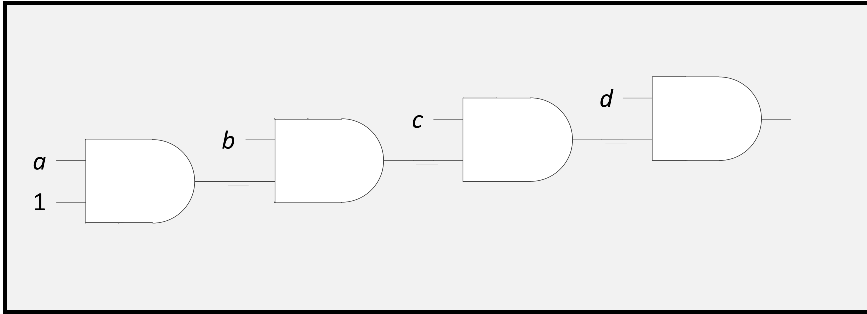
A possible implementation of the policy logic would be to have all the assertions evaluated at the same time to determine if the policy is satisfied. This approach would require that the TPM resources scale with the number of assertions that would need to be evaluated for the policy.

The alternative use in the TPM is to evaluate the expression one assertion at a time with each assertion ANDed with the results of the previous evaluation.

$(((1 \,\&\, a) \,\&\, b) \,\&\, c) \,\&\, d$

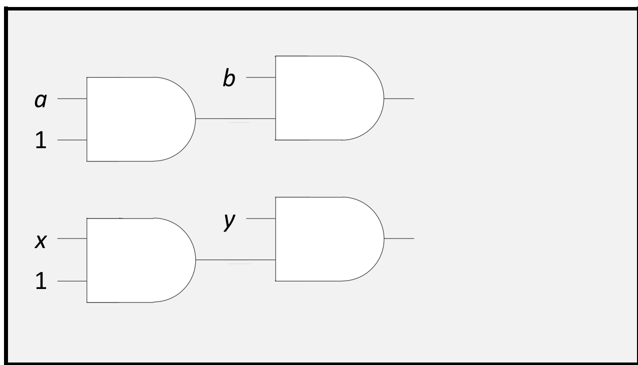
The (1 & *a*) term means that assertion *a* is ANDed with an initial TRUE. This allows each assertion to be just the AND of a new assertion with the results of the previous assertion evaluation. A pictorial representation of the policy evaluation is:

 Copyright © TCG 2006-2020



Any number of assertions can be combined in this way using a fixed set of TPM resources.

The logic of a TPM policy cannot actually be expressed as a simple 1 or 0. For the policy to be valid, not only does it need to evaluate to "TRUE", but it also has to be the correct policy. For example, these two policies may both evaluate to the same logic value (TRUE), but they do not represent the same policies.



So that it can differentiate (*a* & *b*) from (*x* & *y*), the TPM will update a running digest value for each assertion that is added to the policy. The final digest value indicates the policy that was evaluated.

The running digest value is called the *policyDigest*. The *policyDigest* is initialized to a Zero Digest (0…0) when the policy session is started (TPM2_StartAuthSession()). Then, as each policy assertion is evaluated, the *policyDigest* is updated.

$$policyDigest_{new} := \mathbf{H}(policyDigest_{old} \mid\mid PolicyAssertion)$$

NOTE 1 This should be recognizable as the Extend operation.

The *policyDigest* will only be updated if a policy assertion is valid (TRUE) (see 19.7.10 for exception relating to trial policies). This gives an alternative possibility for interpreting the output of one of the policy AND gates. Instead of simply being a 1 (TRUE) or 0 (FALSE), the output of the gate is current value of the *policyDigest*. Using this perspective, the four-term policy becomes:

 Copyright © TCG 2006-2020

where

0…0	the initial value of the policy digest
D1	$\mathbf{H}$(0…0 || *a*)
D2	$\mathbf{H}$(D1 || *b*)
D3	$\mathbf{H}$(D2 || *c*)
D4	$\mathbf{H}$(D3 || *d*)

NOTE 2 In these illustrations, the parameters for the Extend operations are simple parameters ("*a*", "b", etc.). The actual parameters for the Extend are more complex but including the details in the illustrations would add complexity without adding clarity.

19.7.4 Policy OR

If the only type of policy assertion was an AND, then the policies that could be evaluated by the TPM would be of limited value. To make the policies more flexible, an OR policy assertion is defined. As with a logic OR gate, the OR policy assertion will be valid if any of the inputs is valid.

A simple policy using an OR might be written as:

(*a* & *b*) | (*x* & y)

or as:

(((0…0) & *a*) & *b*) | (((0…0) & *x*) & *y*)

Evaluating the AND branches individually, the left side evaluates to:

$$D_{\text{left}} \coloneqq \mathbf{H}(\mathbf{H}(0...0 \mid\mid a) \mid\mid b)$$

and the right side to:

$$D_{\text{right}} \coloneqq \mathbf{H}(\mathbf{H}(0...0 \mid\mid x) \mid\mid y)$$

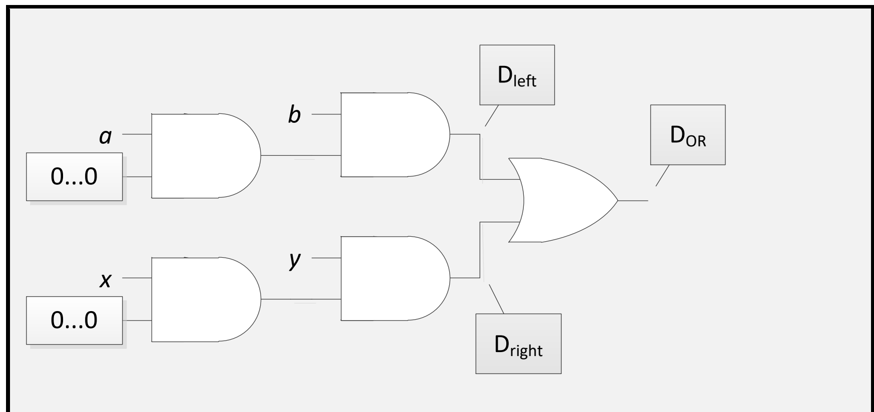
Then, the output from a 2-input policy OR operation will be defined to be

$$policyDigest_{new} \coloneqq \mathrm{H}(D_{\text{left}} \mid\mid D_{\text{right}})$$

Notice that the OR operation replaces the *policyDigest* with a new value instead of Extending it as is done in an AND operation.

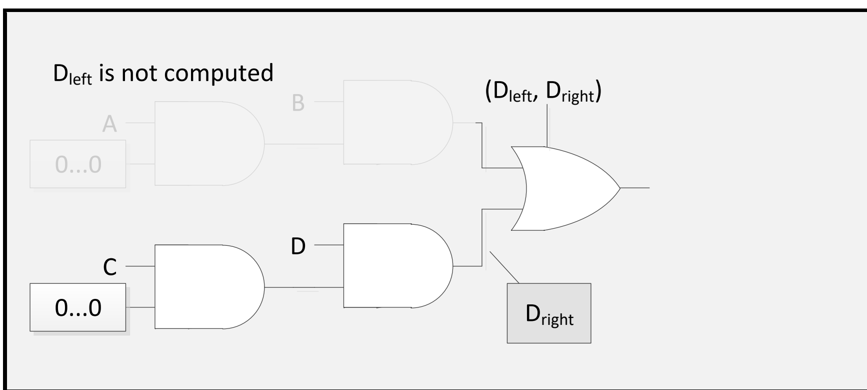
Pictorially, a policy with an OR is:

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019



The TPM processes the OR by comparing the current value of *policyDigest* with a list of digest values provided by the caller. If *policyDigest* is on the list, then the TPM will digest the concatenation of all of the digests in the list. For example, to perform the OR operation above, assume that the TPM has processed (*a* & *b*) producing D_{left}. Then the TPM would be given a list of digests (D_{left}, D_{right}). Because the *policyDigest* is on the list, the TPM computes $D_{OR} \coloneqq \mathbf{H}(D_{left} \mid D_{right})$ and replaces *policyDigest*. Note that if the TPM had processed (*c* & *d*) to compute D_{right} and was then given the same list of digests (D_{left}, D_{right}), the resulting *policyDigest* would be the same.

When processing a policy that has an OR, only one branch of the policy needs to be evaluated. For example, if C and D assertions were valid, then only the *right* branch would need to be evaluated.



The list given to the TPM for a TPM2_PolicyOR() is limited to 8 digests. However, the effective size of the list can be expanded indefinitely by using cascading OR. Figure 15 illustrates one of the many ways to construct a 12 input OR.

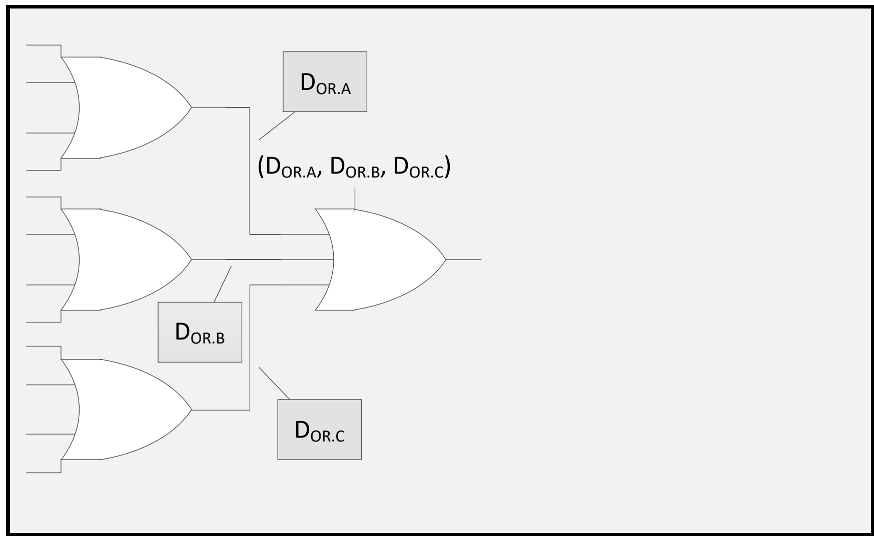


Figure 15 — A 12-input OR Policy

When the OR list can contain 8 digests, 64 different branches can be ORed in just two levels.

The result of an OR operation may be an input to an AND assertion allowing construction of arbitrarily complex policies.

19.7.5 Order of Evaluation

Because the TPM uses digests, the order of evaluations is important. For policy evaluation, (A & B) is not the same as (B & A). In addition, when performing an OR operation, the same list of digests (same number in the same order) must be given to the TPM each time. The list (D_{left}, D_{right}) will not give the same result as (D_{right}, D_{left}) or (D_{left}, D_{right}, D_{other}).

19.7.6 Policy Session Creation

TPM2_StartAuthSession(*sessionType* = TPM_SE_POLICY) is used to start an authorization session. The authorization session may use any of the four options for *tpmKey* and *bind.*

NOTE 1 A policy session does not maintain a binding with a specific object. The bind parameter is used only for session key creation. This allows the context space of the session that is used for the binding value to be dedicated to other policy parameters.

The most typical use of a policy session will be with *tpmKey* and *bind* both set to TPM_RH_NULL. When this option is selected, an HMAC computation might not be performed when the policy session is used and the session *nonce* and *auth* values may be Empty Buffers (see TPM 2.0 Part 3, TPM2_PolicyAuthValue).

NOTE 2 When the session is created, *nonceCaller* still needs to be provided and its size is required to meet the minimum requirements of the command.

When the authorization session is to be used to authorize a command that has an encrypted command or response parameter, then either *tpmKey* or *bind* should be used in the TPM2_StartAuthSession() that starts the session so that a secure *sessionKey* is created.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

19.7.7 Policy Assertions (Policy Commands)

19.7.7.1 Introduction

In TPM 2.0 Part 3 of the specification the set of policy assertions are the commands with names of the form TPM2_Policyxxx() where "xxx" is an indicator of the type of policy assertion. For example, TPM2_PolicySigned() is a policy assertion that an authorization was signed by a specific entity; and TPM2_PolicyPCR() is an assertion that a selected set of PCR have a specific value.

Normally, each policy command will cause the *policyDigest* to be changed in a different way which is why they are different commands. In some cases, the policy command will also cause other changes to the policy session context. For example, TPM2_PolicyLocality() modifies the policy state that indicates the locality that is allowed when the policy session is used for authorization. TPM2_PolicyCommandCode() changes the policy state so that the policy may only be used to authorize a specific command.

The details of the *policyDigest* computation performed by each policy command are provided in the General Description section of each command found in TPM 2.0 Part 3. The description also indicates the policy state that is modified.

The assertions fall into three different groups: immediate, deferred, and combined.

19.7.7.2 Immediate Assertions

For an immediate assertion, the input values are validated and the TPM will return a failure and not update the *policyDigest* if the assertion is not valid. An example of an immediate assertion is TPM2_PolicyNV(). For this assertion, the TPM validates the logical or arithmetic relationship between an input value and an NV Index. If the specified relationship is not valid, the TPM returns an error and the *policyDigest* is not modified. If the relationship is valid, then the *policyDigest* is updated with the Index Name and the relationship that was validated.

19.7.7.3 Deferred Assertions

For a deferred assertion, the TPM will update the *policyDigest* based on the input values and record some parameters in the policy session's context. These parameters are checked when the policy is used for authorization. An example of a deferred assertion is TPM2_PolicyCommandCode(). For this assertion, the input is a TPM command code. The *policyDigest* will be updated to record the fact that the TPM2_PolicyCommandCode() was executed and the *commandCode* value that was specified. The TPM also directly records the *commandCode* parameter in the policy session context. When the policy is used for authorization, the TPM will verify that the command being authorized is the same as the command in the policy and the authorization (and command) will fail if they are not the same.

19.7.7.4 Combined Assertions

For a combined assertion, the TPM will validate some condition of the input and record or modify some parameters in the policy session's context. An example of a combined assertion is TPM2_PolicySigned(). For this assertion type, the TPM validates that the parameters of the command have been signed by the indicated key. If so, it will update the policy session context based on the input parameters. One of the context values that may be updated is the *cpHash* of the session. If the *cpHash* of the authorized command is not the same as the authorized *cpHash* then the command will not be authorized.

19.7.7.5 Repetition of Assertions

In general, any policy assertion may occur multiple times within a policy as long as the assertion is compatible with previous assertions. An example of an incompatible set of assertions is two occurrences of TPM2_PolicyCommandCode() that specify different command codes.

The TPM will return an error if an assertion is incompatible with a previous assertion. It is possible that the failed assertion is incompatible with an assertion of a different type. For example, a TPM2_PolicyCpHash() may be incompatible with a TPM2_PolicySigned(). If they specify different values of *policySession→cpHash,* then the TPM will return an error.

NOTE When referring to an *element* of the policy context, the notation *policySession→element* is used to denote a particular member of the policy context.

19.7.7.6 List of Assertions

The assertions listed in this clause will all update the *policyDigest* of the policy session being operated on if the assertion condition is met. They may also cause a change to other policy session, context values (the list of policy session context values is in 19.7.8) as indicated in the brief description for each assertion.

 Copyright © TCG 2006-2020

- **TPM2_PolicyAuthorize()** – valid if *policySession→policyDigest* has the value authorized by the selected key. This is an immediate assertion and is described in more detail in 19.7.11.
- **TPM2_PolicyAuthorizeNV()** – valid if the specified NV Index contains a hash algorithm identifier and a digest value that match the hash algorithm and *policySession→policyDigest*. This immediate assertion changes *policySession->policyDigest* and is described in more detail in 19.7.11.
- **TPM2_PolicyAuthValue()** – valid if *authValue* of the authorized entity is provided when the policy session is used for authorization. This deferred assertion will SET *policySession→isAuthValueNeeded*. When the policy is used for authorization, the TPM will check *policySession→isAuthValueNeeded*. If it is SET, then the TPM performs an HMAC check on the session as if it were an HMAC session. This HMAC validation will only succeed if the caller is able to prove knowledge of the entity's *authValue* by computing the correct HMAC.
- **TPM2_PolicyCommandCode()** – valid when the authorized command has the specified command code. This deferred assertion sets *policySession→commandCode*.
- **TPM2_PolicyCounterTimer()** – valid when a portion of the TPM's TPMS_TIME_INFO structure has the desired numerical relationship with another value. This is an immediate assertion. If the selected subset of the TPM's TPMS_TIME_INFO structure does not have the specified relationship with the input data, then the TPM will return an error and not change the *policyDigest* (see 36.1 for use cases).
- **TPM2_PolicyCpHash()** – valid if the cpHash of the authorized command has a specific value. This deferred assertion *modifies policySession→cpHash*.
- **TPM2_PolicyDuplicationSelect()** – valid if the handles of the authorized command reference specific objects and the command code is TPM2_Duplicate(). This deferred assertion modifies *policySession→cpHash* and *policySession→commandCode*.
- **TPM2_PolicyLocality()** – valid if the command being authorized is being executed at one of the allowed localities. This is a deferred assertion that modifies *policySession→locality*. For localities 0-4, the input locality parameter is a bit field that indicates the allowed localities. If an execution of this assertion would result in no locality being allowed, then the TPM will return an error. For extended localities, *policySession→locality* is set to the *locality* parameter of the command if the *policySession→locality* was not previously set. Otherwise, the *locality* parameter is required to be the same as the current value of *policySession→locality.*
- **TPM2_PolicyNameHash()** – valid if the handles of the authorized command reference specific objects. This deferred assertion modifies *policySession→cpHash.*
- **TPM2_PolicyNV()** – valid if the contents of NV have the desired relationship with another value. This is an immediate assertion. If the selected portion of the NV Index does not have the specified relationship with the input data, then the TPM will return an error and not change the *policyDigest.*
- **TPM2_PolicyNvWritten()** – valid when the TPMA_NV_WRITTEN attribute of the specified NV Index has the desired value. This deferred assertion sets *policySession→checkNvWritten* and the state of *policySession→nvWrittenState*.
- **TPM2_PolicyOR()** – valid if *policySession→policyDigest* is on a list of digests. This is an immediate assertion. If *policySession→policyDigest* is not on the list of digests, then TPM returns an error. Otherwise, *policySession→policyDigest* is replaced with the digest of the list.
- **TPM2_PolicyPassword()** – valid if the *authValue* of the authorized entity is provided when the session is used for authorization. This deferred assertion will SET *policySession→isPasswordNeeded*. When the policy is used for authorization, the TPM will check *policySession→isPasswordNeeded*. If it is SET, then the TPM performs a password check on the session as if it were a password session. . This password validation will only succeed if the caller is able to prove knowledge of the entity's *authValue* by providing the correct value as the password.

NOTE 1 A session may use TPM2_PolicyAuthValue() and TPM2_PolicyPassword() interchangeably. If TPM2_PolicyAuthValue() and TPM2_Policy Password() are both used, then TPM will perform the check according to the last one used in the policy.

- **TPM2_PolicyPCR()** – valid if the selected PCR have the desired value. This assertion may be either a combined or a deferred assertion. If the caller provides a digest, the TPM validates that the current values of the PCR match the input value and return an error (TPM_RC_VALUE) if not. If this command completes successfully, the *policyDigest* will have been updated with the digest of the selected PCR. The TPM will also record that the PCR have been checked. If the PCR are changed after they are checked but before the policy is used for authorization, then the policy will fail.

NOTE 2 The reference implementation provides this assurance by maintaining a PCR update counter that increments each time the PCR are modified. The update counter is saved in the policy session context. If the update counter does not change between the check of the PCR and the use of the policy session for authorization, then the PCR are the same.

- **TPM2_PolicyPhysicalPresence()** – valid if the physical presence is asserted when the authorized command is executed. This deferred assertion sets *policySession→isPPRequired.*
- **TPM2_PolicySecret()** – valid if the knowledge of a secret value is provided. This assertion is an immediate and possibly also a deferred assertion. Based on the input parameters, this command may modify *policySession→cpHash* and *policySession→timeout.*

NOTE 3 The secret value will be the *authValue* of some TPM entity.

- **TPM2_PolicySigned()** – valid if the parameters are properly signed. This assertion is an immediate and possibly also a deferred assertion. Based on the input parameters, this command may modify *policySession→cpHash* and *policySession→timeout.*
- **TPM2_PolicyTemplate()** – valid if the hash of the *inPublic* parameter of TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded() matches the *templateHash* in this command. This deferred assertion sets *policySession→cpHash.*
- **TPM2_PolicyTicket()** – valid if the ticket is valid. This assertion is an immediate and possibly also a deferred assertion. Based on the input parameters, this command may modify *policySession→cpHash* and *policySession→timeout*.

19.7.8 Policy Session Context Values

A policy session context contains the state and tracking information for evaluation of a policy. The context values are set to their default values when the session is created and again each time the session is successfully used to authorize a command.

The values may be changed by a policy assertion. The policy assertions are listed in 19.7.7.6 with an indication of the policy session context values that they modify. The policy session context values are described further here.

- ***policyDigest*** – digest that is updated by each assertion. The default value for *policyDigest* is a Zero Digest (a buffer with a length equal to the digest size of the hash algorithm with all octets having a value of zero).
  - ***nonceTPM*** – set from the RNG and is sized according to the size of *nonceCaller* in TPM2_StartAuthSession(). This value does not change during the policy evaluation. However, it does change when the policy session is used for authorization.
  - ***cpHash*** – set by an assertion that limits the authorization to a specific set of command parameters. If an assertion would set *policySession→cpHash* and a previous assertion has set *policySession→cpHash* to a different value, then the assertion will fail. The default for *policySession→cpHash* is an Empty Buffer.
  - ***nameHash*** – set by TPM2_PolicyNameHash() and indicates the combination of Name values for a command. This context parameter occupies the same location as *policySession→cpHash*. If an assertion would set *policySession→cpHash* and a previous assertion has set *cpHash* to a different value, then the assertion will fail. The default for *policySession→nameHash* is an Empty Buffer.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

- ***startTime*** – set to TPMS_TIME_INFO.*clockInfo.clock* when *policySession→nonceTPM* changes. No assertion changes this value. It is updated to the current value of *clock* by TPM2_StartAuthSession() and when the session is used for authorization.
- ***timeout*** – the time when the policy session expires. Its default setting is an implementation-specific value corresponding to "never expires." This value is updated if an assertion has a non-zero expiration time that is sooner than the current setting of *policySession→timeOut*. An assertion may only decrease the value of *policySession→timeout.*
- ***commandCode*** – set by an assertion that limits the policy to a specific command but does not limit the command parameters (TPM2_PolicyCpHash() limits the command and its parameters). If an assertion sets *policySession→commandCode* and a previous assertion has set *policySession→commandCode* to a different value, then the TPM will return an error. The default for *policySession→commandCode* is an implementation-specific value that indicates that it has not been set.
- ***pcrUpdateCounter*** – set by TPM2_PolicyPCR(). The TPM maintains a *pcrUpdateCounter* that is incremented each time a PCR changes (with a few exceptions as described in 17.9). When it executes TPM2_PolicyPCR(), the TPM will copy *pcrUpdateCounter* to *policySession→pcrUpdateCounter.* When the policy session is used for authorization, the TPM will verify that *policySession→pcrUpdateCounter* matches *pcrUpdateCounter.* A match provides assurance that the PCR values still match the values evaluated by TPM2_PolicyPCR().
- ***commandLocality*** – indicates the locality required for the command being authorized by the policy. The default for *policySession→commandLocality* is any locality. Each locality that is not enabled in TPM2_PolicyLocality(*locality)* is disabled in *policySession→commandLocality*. If the result of this operation would result in there being no locality at which the policy would be valid, the TPM will return an error and not change *policySession→commandLocality*. If *commandLocality* is set to an extended locality (greater than 31), then the locality cannot be change by subsequent TPM2_PolicyLocality().
- ***isPPRequired*** – SET by TPM2_PolicyPhysicalPresence() to indicate that presence is required to be asserted when authorized command is executed. The default value is CLEAR.
- ***isAuthValueNeeded*** – SET by TPM2_PolicyAuthValue()to indicate that the *authValue* of the authorized entity will need to be provided when the policy session is used for authorization. The *authValue* is required to be included in an HMAC. The default value is CLEAR. It will also be CLEAR by TPM2_PolicyPassword()
- ***isPasswordNeeded*** – SET by TPM2_PolicyPassword() to indicate that the *authValue* of the authorized entity will need to be provided when the policy session is used for authorization. The *authValue* is required to be provided as a password. The default value is CLEAR. It will also be CLEAR by TPM2_PolicyAuthValue().
- ***isTrialPolicy*** – SET to indicate that policySession→policyDigest is to be updated even if the assertion is not valid. The session may not be used for authorization.
- ***checkNvWritten* –** SET to indicate that the TPMA_NV_WRITTEN attribute of the authorized NV Index must be compared with *nvWrittenState.*
- ***nvWrittenState*** – SET when TPMA_NV_WRITTEN is required to be SET in the NV Index being authorized. This attribute has no meaning when ***checkNvWritten*** is not SET.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

19.7.9 Policy Example

In TPM 1.2, the basic policy for use of a key was limited to a combination of an authorization value and PCR state. This policy was built in to each key. In TPM 2.0 there is no built-in policy. A TPM 2.0 policy that is the same as the TPM 1.2 policy is:

TPM2_PolicyPCR() & TPM2_PolicyAuthValue()

Note This policy could also be written as

TPM2_PolicyAuthValue() & TPM2_PolicyPCR()

This policy would have a different *policyDigest* because the order of evaluation affects the digest.

To associate this policy with a key, evaluate the policy to determine the *policyDigest* that it would generate. Then create the key with this digest as the *authPolicy* and CLEAR the *userWithAuth* attribute. When *userWithAuth* is CLEAR, USER mode actions for the key will require use of the key's *authPolicy*.

19.7.10 Trial Policy

The policy evaluation to determine the value for the *authPolicy* may be done in software that does the same *policyDigest* computation as the TPM. Alternatively, a trial policy session may be used. A trial policy session is created and used in a sequence of policy commands just like a normal policy session. The difference is, in a trial policy, a policy assertion is always assumed to be TRUE and the *policyDigest* updated accordingly. The *policyDigest* value computed in the trial policy can be read from the TPM and used as an object's *authPolicy*. Since the assertions in the trial policy do not need to be valid, the trial session may not be used for authorization.

19.7.11 Modification of Policies

Some policies, such as those associated with the hierarchies, may be altered directly by changing the *authPolicy* value. Policies associated with Objects and NV Indices may not be directly altered. The reason that these policies may not be altered is that the policy can affect the trust that someone places in the use of that entity. For example, a key may only be trusted if it may only be used when the PCR have a specific set of values. If the policy could be changed, then the PCR check could be removed, and the key would no longer be trusted. There would be no way for the trusting entity to know if a version of the key exists where the PCR are not checked.

Even though there is no way to directly change a policy, it can be indirectly changed. The command that allows this is TPM2_PolicyAuthorize(). When this command is included in a policy, it allows a designated entity (an "authority") to authorize a *policyDigest* to be included in the policy. This is best described with an example.

It is common to seal a data value to PCR values so that the data value can only be recovered if the platform has booted in a known way. A problem with this is that if there is a BIOS update, the PCR will change, and the sealed data value can no longer be retrieved, and some kind of recovery process is necessary. The inability of a policy to accommodate changes to PCR values is called "brittleness". That term suggests that the policy is easy to break (make unusable). This brittleness could be a problem with TPM 2.0 if the policy was completely fixed.

Figure 16 illustrates the use of TPM2_PolicyAuthorize() to implement a flexible policy. This assertion evaluation checks to see if the current *policyDigest* is authorized by a signing key – that is, did an authorizing entity sign a digest indicating that a specific value of *policyDigest* represents a known set of PCR values. If the *policyDigest* value was signed, then *policyDigest* is replaced by a digest of the Name of the key that was used for authorization and *policyRef* (see 19.7.12).

 Copyright © TCG 2006-2020

NOTE 1 Other information is included with the Name of the key when the new *policyDigest* is computed in order to indicate that the Name was included as the result of a TPM2_PolicyAuthorized() operation.

NOTE 2 This example purposefully avoids using terms that would indicate that the signing entity does anything other than indicate that the PCR values are the expected values. In particular, the signing entity does not have to certify that the PCR values are safe. The signing entity may provide other assurances but, in the case of PCR, it is not necessary to warrant anything other than that the PCR values are expected.

An example of how of this assertion type may be used to avoid PCR brittleness is shown in Figure 16. This shows the example policy in 19.7.9 but with the ability to satisfy the policy with different PCR values.

NOTE 3 The actual *authPolicy* in the authorized entity would contain (PolicyAuthorize & PolicyAuthValue).

As shown, a PolicyPCR assertion is followed by PolicyAuthorize(). If there is an authorization signed by KEY for the current *policyDIgest* (in this case, $D_{PCR.A}$), then the result of the PolicyAuthorize() will be D_{KEY}. This is the same output that would be produced if the input to the PolicyAuthorize() were $D_{PCR.B}$ and there was an authorization sighed by KEY for $D_{PCR.B}$. That is, in TPM2_PolicyAuthorize(), if the key authorized the current *policyDigest*, *policyDigest* reset to a Zero Digest and then extended with the Name of the key. The *policyDigest* value D_{final} no longer reflects the previous value ($D_{PCR.A}$ or $D_{PCR.B}$).

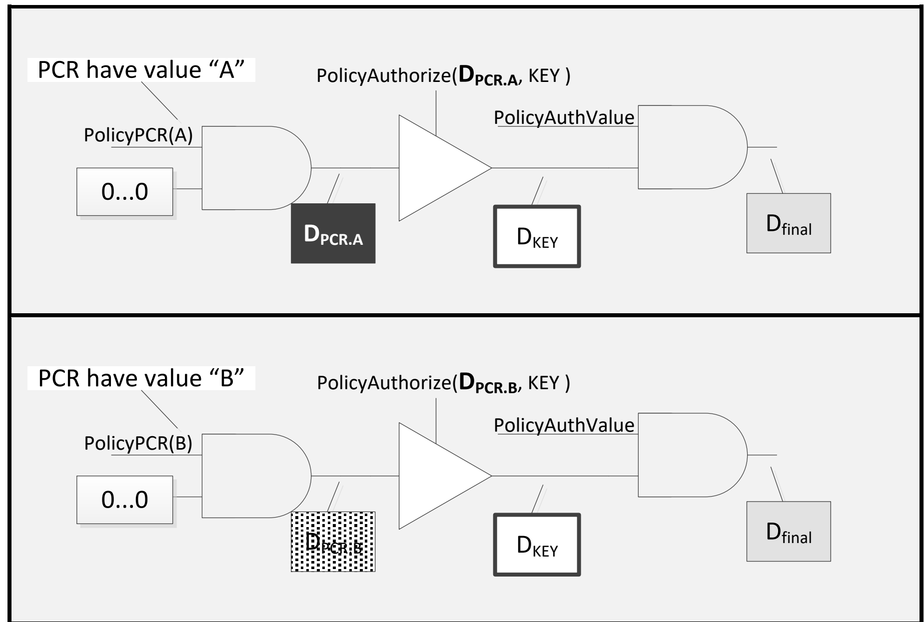

Figure 16 — Use of TPM2_PolicyAuthorize() to Avoid PCR Brittleness

In the case of a BIOS update that changes PCR, the platform OEM could provide a signature for the PCR values created by the new BIOS. Now, if the policy of the sealed data includes a TPM2_PolicyAuthorize() from the OEM, then the BIOS can be updated, and no recovery process would be needed to deal with the new PCR values. That is, with either authorized set of PCR, D_{KEY} and D_{final} will be the same, even though $D_{PCR.A}$ and $D_{PCR.B}$ are different.

An additional way to indirectly modify a policy uses TPM2_PolicyAuthorizeNV(). This command specifies an NV Index location of a policy that will be effective for an entity, the effective policy being the policy digest stored in the data at that NV index. When a policy is formed using TPM2_PolicyAuthorizeNV(), the NV Index Name is specified. When the entity is to be authorized, the policy stored in the data of the named index is satisfied, and then TPM2_PolicyAuthorizeNV() is executed. If the policy stored in that index matches the *policySession->policyDigest*, then the *policySession->policyDigest* is replaced with results of first setting the *policySession->policyDigest* to the Zero Digest, and then extending it with the command code concatenated with the name of the NV index, which will contain the modified policy. The

 Copyright © TCG 2006-2020

main difference between this command and TPM2_PolicyAuthorize() is that multiple policies can satisfy TPM2_PolicyAuthorize(), as long as they are all signed with the appropriate key. Only the policy that is currently stored in the NV index can satisfy TPM2_PolicyAuthorizeNV().

19.7.12 TPM2_PolicySigned(), TPM2_PolicySecret(), and TPM2_PolicyTicket()

The set of assertions discussed in this clause have properties that enable a number of authorization scenarios. Among these are:

- the ability to grant an authorization that can persist for a specific amount of time (because in many protocols, access to a resource (such as, a network) is granted for some time interval); and
- the ability to associate an authorization with a policy of the authorizing entity (because in many instances, the authorizing entity may use the same key or secret for different purposes).

TPM2_PolicySigned() and TPM2_PolicySecret() convey an authorization by signing a set of parameters that indicate the nature of the authorization. With TPM2_PolicySigned() the signature is with a key value (symmetric or asymmetric) and with TPM2_PolicySecret() the signature is with an HMAC using an *authValue* in the HMAC key.

The policy assertions of TPM2_PolicySigned() and TPM2_PolicySecret() can be time limited. When a policy's authorization is time limited, it expires (is no longer valid) when TPM *Time* is greater than the indicated value for the authorization. An expiration time can be expressed in two ways. A *timeout* is an absolute value of *Time*. An *expiration* value is a relative value in seconds from the start *Time* of the policy session to which the authorization applies.

Both TPM2_PolicySigned() and TPM2_PolicySecret() can produce tickets that enable authorizations to be used and reused over a period of time and in different policy sessions. These tickets are used in TPM2_PolicyTicket().

These three commands have several input parameters in common:

- **nonceTPM** – the value returned by TPM2_StartAuthSession() or when a session is used for an authorization. It is used to limit the use of a policy assertion to a specific policy session. If a policy command includes a *nonceTPM,* then the TPM will return an error if it does not match *policySession→nonceTPM*.
- **cpHashA** – if the caller chooses to limit the authorization to a specific command and command parameters, they would include this value in the signed data structure. Use of this parameter allows the caller to provide an authorization that is similar to the HMAC authorization. That type of authorization is only valid for a specific command and set of command parameters. If this parameter is not part of the signed authorization, then this parameter should be set to the Empty Buffer.
- **policyRef** – in some circumstances, it is desirable to have an authorization convey some information relating to the authorizing entity. For example, a fingerprint reader may have a signing key that it uses to verify when it has recognized a fingerprint regardless of whose fingerprint it might be. This type of authorization would be difficult to use if it were not possible to indicate whose fingerprint was scanned. The *policyRef* parameter would allow the fingerprint reader to provide this indication. The TPM includes this value in the *policyDigest*. In the example of the fingerprint reader, this would mean that the *policyDigest* would only have the correct value if the fingerprint reader scanned a finger from the correct person. If this parameter is not part of the signed authorization, then this parameter should be an Empty Buffer.

  NOTE 1 Because TPM2_PolicySigned() does not include the *cpHashA* and *policyRef* size in the *aHash* calculation, it is recommended that the size of *policyRef* not be the same size as that of the entity Name algorithm.

 Copyright © TCG 2006-2020

- **expiration** this parameter is used to place a time limit on an authorization. It is either the number of seconds from the last time that the *nonceTPM* of a policy session was changed, or the value of Time after which a policy assertion is no longer valid.
- **timeout –** this indicates the value of *Time* after which a policy assertion is no longer valid.

If a TPM2_PolicySigned() or TPM2_PolicySecret() has a non-zero *expiration* parameter:

- If *nonceTPM* is not included, *expiration* is a *timeout.*
- If expiration is a negative number, a ticket will be produced

NOTE 2 For TPM2_PolicySecret(), if *authHandle* references a PIN Pass Index, then no ticket will be produced even if *expiration* is negative. This prevents use of a ticket to bypass the limit count on an PIN Pass Index.

When a policy session is started, a *nonceTPM* is generated and the current value of *Time* is copied to *policySession→startTime*. When a policy assertion includes a non-zero *expiration* and a *nonceTPM*, then *policySession→startTime* is added to the absolute value of *expiration* to determine the *timeout* for the policy assertion. If a policy assertion includes a non-zero value in its *expiration* parameter but no *nonceTPM*, then the *expiration* parameter is used directly as a *timeout*

When an assertion produces a *timeout*, the *timeout* value is placed in *policySession→timeout.* If *policySession→timeout* has previously been set, then it will be updated with the lesser of *timeout* and *policySession→timeout*.

When *Time* has a greater value than *policySession→timeout,* the policy session expires and cannot be used for authorization. If the authorization used a *timeout* (no *nonceTPM*), then the authorization will also expire on the next TPM Reset.

NOTE 3 A policy assertion includes an *expiration* when the *expiration* parameter is non-zero. A policy assertion includes a *nonceTPM* when its *nonceTPM* parameter is not the Empty Buffer.

NOTE 4 *expiration* may need to be converted to milliseconds before being added to *policySession→startTime.*

NOTE 5 When an *expiration* parameter is used directly as a *timeout, expiration* is the value of Time in seconds when the assertion expires. When an assertion contains a *timeout* parameter (only in TPM2_PolicyTicket()), *timeout* is an implementation-dependent value.

A ticket contains a digest of the command parameters of the assertion along with a ticket *timeout*. As long as a ticket has not expired, its effect on a *policySession→policyDigest* and *policySession→timeout* will be the same as the TPM2_PolicySigned() or TPM2_PolicySecret() command that generated the ticket. For example, one may use a TPM2_PolicySigned() command with an expiration of -3600 (the negative of the number of seconds in an hour) to return a ticket. For the next hour, that ticket can be used with TPM2_PolicyTicket() to grant whatever other permissions were approved by the TPM2_PolicySigned() command.

When the TPM is not able to report the passage of time (*Time* does not advance), accurate timing of assertions is not possible. To prevent having a timed assertion persist past the intended timeout, a TPM is required to invalidate any time based assertion that was created before a discontinuity in the TPM's measurement of time. Such a discontinuity can occur when *Time* does not advance or when *Time* is reset. This requirement is met by having a number (a counter or a nonce) that changes each time that there is a time discontinuity (an epoch) and by including *timeEpoch* in the computation of time-based assertions. This implies that each policy session will need to:

 Copyright © TCG 2006-2020

- record *timeEpoch* when the session is created (in *policySession→timeEpoch*);
- validate that the *timeEpoch* associated with a time-limited assertion is the same as *policySession→timeEpoch* before the assertion is accepted; and
- when a time-limited policy is used for authorization, verify that the current TPM *timeEpoch* matches *policySession→timeEpoch.*

If a counter is used for *timeEpoch*, it needs to be saved in NV memory whenever it changes. If the number used for *timeEpoch* is a nonce, it can be kept in RAM and changed on each time discontinuity.

NOTE 6 A *timeEpoch* nonce needs to be large enough that a replay is infeasible. That is, a ticket issued with a given nonce should not be useable after a future power cycle because the nonce values happen to match. In the context of a specific ticket, a nonce collision is not a "birthday problem" as the nonce has to match exactly rather than being one of a group of values that are equivalent.

19.7.13 Use of TPM for authPolicy Computation

To use a policy for authorization for an object or NV Index, the creator of an object or NV Index is required to know, at the time of creation of the Object or NV Index, the digest of the policy. The computation of this policy requires duplication of the steps that would be performed by the TPM when it evaluates the policy and updates the accumulated *policyDigest* of the session.

This computation can be done by software but would require that the policy update process for each command be replicated by software. As an alternative, the TPM can be used to perform the computation.

To use the TPM, a policy session is created, and various policy commands are sent to the TPM as if the policy were being evaluated in order to authorize an action. TPM2_PolicyGetDigest() may then be used to read the final *policyDigest* from the TPM. That *policyDigest* value may then be used as the *authPolicy* parameter in a new Object/NV Index.

NOTE There is no requirement that the *authPolicy* for each Object or NV Index be unique.

If the policy is complex and uses TPM2_PolicyOR(), it will be necessary to compute multiple *policyDigest* values. The same policy session can be used for all of the computations by using TPM2_PolicyRestart() after the *policyDigest* for a branch is computed. When the last branch is computed, it may be used in a TPM2_PolicyOR that is constructed from the previously computed values.

TPM2_PolicyGetDigest() could also be used to help validate the software that is implementing the digest computation. The value computed by the TPM can be compared to the value computed by the software library to ensure that they are the same. If desired, TPM2_PolicyGetDigest() can be called after each policy command.

19.7.14 Trial Policy Session

If a policy requires a signed (symmetric or asymmetric) authorization for an action, that authorization may not be available at the time that the Object/NV Index is created, and, in fact, the authorizing entity might not be willing or able to provide the necessary authorization at the time of creation.

EXAMPLE 1 If the Object is to have a duplication authorization, the duplication authority may not provide the authorization for the duplication when the Object is created. If they did, then the migration policy could be computed; the *policyDigest* of the session read and placed in a new Object, and immediately used for duplication of the Object. The duplication authority may not want to allow the duplication at that time.

The TPM provides a special type of policy session to be used for the purpose of computing the policy without enabling the use of the policy. When a session is created by TPM2_StartAuthSession(*policyType*

 Copyright © TCG 2006-2020

= TPM_SE_TRIAL), a policy session is created that cannot be used for authorization. Since it cannot be used for authorization, authorizations are not needed in the computation of the policy.

EXAMPLE 2 If TPM2_PolicySigned() is called to update the digest of a trial policy session, the signature is not validated but the *policyDigest* is updated as if a correct signature was provided.

19.7.15 Use of TPM2_PolicySigned() and TPM2_PolicySecret() without *nonceTPM*

The primary purpose of including *nonceTPM* in TPM2_PolicySigned() and TPM2_PolicySecret() is to restrict the use of the policy assertion to a specific policy session so that the assertion may only be used once.

nonceTPM serves a different purpose when the assertion is structured so that a ticket is produced. In that case, the intent is that the assertion can apply to more than one policy session, so *nonceTPM* serves a different purpose – to associate the assertion with a specific TPM. That is, a non-zero expiration causes the TPM to produce a ticket. If the signer did not include *nonceTPM*, its signature could be used with any session and therefore on any TPM. Including *nonceTPM* binds the signature to a specific session, and thus a specific TPM. The signer forces the ticket to be created on a specific TPM, which ties the ticket to a timer on that TPM.

Each *nonceTPM* is expected to be statistically unique and not appear on any other TPM (this is just expected to be true and not required to be true). Therefore, when an assertion includes *nonceTPM,* the assertion will only be usable on one policy session on a specific TPM.

NOTE When a ticket is produced, that ticket is always restricted to use on a specific TPM because of the use of TPM- and hierarchy-specific proof values in the ticket computation.

When the policy assertion does not include *nonceTPM,* then is it possible to use the assertion with any policy session. For TPM2_PolicySecret() the assertion may still be associated with a specific TPM if the authorization for the *authObject* uses an HMAC or policy session. This is because that authorization session will be TPM specific. For TPM2_PolicySigned(), when there is no *nonceTPM* in the assertion, then the assertion may be used on any policy session on any TPM where the public part of *authObject* may be loaded (that is, any TPM that is compatible with this specification). This may be suitable when an assertion is limited to performing specific actions (through *cpHash*) or specific policies (though *policyRef*), but this capability should be used with caution.

19.8 Dictionary Attack Protection

19.8.1 Introduction

The TPM incorporates mechanisms that provide protection against guessing or exhaustive searches of authorization values stored within the TPM.

The dictionary attack (DA) protection logic is triggered when the rate of authorization failures is too high. If this occurs, the TPM enters Lockout mode in which the TPM will return TPM_RC_LOCKOUT for an operation that requires use of a DA protected *authValue*. Depending on the settings of the configurable parameters described below, the TPM can “self-heal” after a specified amount of time or be programmatically reset using proof of knowledge of an authorization value or satisfaction of a policy

The *authValue* for an object receives DA protection unless the object's *noDA* attribute is SET. The *authValue* for an NV Index receives DA protection unless the TPMA_NV_NO_DA attribute of the Index is SET. The *authValue* associated with a permanent entity, other than TPM_RH_LOCKOUT, does not receive DA protection. Sequence objects created by TPM2_HMAC_Start() and TPM2_HashSequenceStart() do not receive DA protection.

 Copyright © TCG 2006-2020

NOTE 1 Authorization values associated with permanent entities, other than TPM_RH_LOCKOUT, are expected to be high-entropy values that are managed by a computer or will be well-known values, In either case, they will not need DA protection. While it is safer when *lockoutAuth* is a high-entropy value, it is possible that *lockoutAuth* will be a value chosen to be remembered by a human which will likely have less entropy than other permanent entities. As a consequence, *lockoutAuth* is DA protected even though it is a permanent entity.

The reason for being able to exclude entities from DA protection is that lockout of all TPM use could make the system unstable. The OS may have uses for the TPM that should not be blocked due to authorization problems with keys associated with user-mode applications. The OS is expected to use a well-known or high-entropy *authValue* for any entities that it manages and an *authValue* of neither type needs DA-protection.

An *authValue* may be used for authorization in three ways:

1) a password;
2) the *authValue* parameter in the HMAC computation of equation (17); or
3) the *authValue* parameter in the computation of *sessionKey* for a bound session as shown in equation (18).

All uses of a DA protected *authValue* receive DA protection.

NOTE 2 A TPM PIN Index provides a type of DA protection for an individual TPM entity. This is described in37.2.8.

19.8.2 Lockout Mode Configuration Parameters

The TPM uses four, 32-bit, non-volatile state variables to control the initiation and recovery from the DA-lockout mode.

NOTE The "NV" notation indicates that these values are required to be held in persistent memory and be updated in NV when they change

a) ***failedTries*** (NV) – This counter is incremented when the TPM returns TPM_RC_AUTH_FAIL. TPM2_Clear() will reset this counter to zero. This counter is also set to zero on a successful invocation of TPM2_DictionaryAttackLockReset(). This counter is decremented by one after *recoveryTime* seconds if:
   1) the TPM does not record an authorization failure of a DA-protected entity,
   2) there is no power interruption, and
   3) *failedTries* is not zero.

NOTE 1 If the TPM has a trusted source of time that runs when TPM power is lost, then *failedTries* may be reduced when power is restored. The amount that *failedTries* is decremented would be dependent on the duration of the power loss and the value of *recoveryTime*.

NOTE 2 The TPM may keep track of the time elapsed toward *recoveryTime* at shutdown and use that against the *recoveryTIme* upon power up.

b) ***maxTries*** (NV) – The TPM is in Lockout mode as long as *failedTries* equals this value. When a new owner is installed, *maxTries* is set to its default value as specified in the relevant platform-specific specification.

c) ***recoveryTime*** (NV) – This value indicates, in seconds, the rate at which *failedTries* is decremented. This can be set to a large value (2^{32} - 1) which essentially inhibits automatic exit from Lockout mode. When a new owner is installed, this value is set to its default value as specified in the relevant platform-specific specification.

d) ***lockoutRecovery*** (NV) – This value indicates the delay in seconds between attempts to use *lockoutAuth*. The time delay only applies after an authorization failure using *lockoutAuth*. A value of zero indicates that a system reboot (TPM2_Startup(TPM_SU_CLEAR)) is required between lockout attempts.

The parameters *maxTries*, *recoveryTime*, and *lockoutRecovery* are set with TPM2_DictionaryAttackParameters(). This command requires Lockout Authorization.

19.8.3 Lockout Mode

The TPM is in Lockout mode while failedTries is equal to *maxTries*. While in Lockout mode, any use of a DA-protected *authValue* will return TPM_RC_LOCKOUT.

NOTE 1 An exception is that TPM2_DictionaryAttackLockReset() is allowed to execute even though *lockoutAuth* is DA protected.

NOTE 2 If there is an authorization failure that does not increment *failedTries*, the TPM returns TPM_RC_BAD_AUTH

An authorization failure may occur with a password or an HMAC. For a policy authorization, the policy is validated before the HMAC is computed. If the policy fails, the TPM returns TPM_RC_POLICY to indicate that dictionary attack protection was not involved.

NOTE 3 A policy authorization does not always have an associated HMAC.

19.8.4 Recovering from Lockout Mode

The TPM can recover from Lockout mode in three ways.

1) TPM2_DictionaryAttackLockReset() sets *failedTries* to zero. This command requires Lockout Authorization. The TPM does not have to be in Lockout mode in order to use this command.
2) The TPM decrements *failedTries* by one if no TPM resets are recorded during *recoveryTime*.

NOTE 1 If the TPM is in Lockout mode, then the TPM will always leave Lockout mode when *failedTries* decrements because *failedTries* will no longer be equal to *maxTries*.

NOTE 2 The failure count is not decremented below zero.

3) *failedTries* is set to zero if the owner changes.

Configuration and programmatic recovery of the dictionary attack logic requires proof of knowledge of Lockout Authorization. When the TPM owner is changed by changing the SPS, *lockoutAuth* is set to the EmptyAuth and *lockoutPolicy* is set to the Empty Buffer

TPM2_DictionaryAttackLockReset() allows external software to reset the dictionary attack protection logic by providing Lockout Authorization. This command can be used when the TPM is in Lockout mode.

19.8.5 Authorization Failures Involving *lockoutAuth*

When *lockoutAuth* is used in an authorization and that authorization fails, the TPM enters a lockout state intended to provide special protection for the *lockoutAuth* value. An authorization failure associated with *lockoutAuth* causes the TPM to enter this special lockout state regardless of the setting of *failedTries* and *maxTries*.

When in this special lockout state, the TPM will not allow use of *lockoutAuth*. The TPM will exit this state when TPM2_DictionaryAttackLockReset() is used with a successful lockoutPolicy or after the TPM is

 Copyright © TCG 2006-2020

powered for a configurable time period (*lockoutRecovery*). If *lockoutRecovery* is set to zero, then the TPM will not exit this state until the next TPM2_Startup() or until lockoutPolicy is used.

NOTE The design depends upon the trusted computing base to filter commands to the TPM such as TPM2_DictionaryAttackLockReset(). This prevents a rogue application from completing a denial of service attack on the TPM by intentionally sending the command with a bad *lockoutAuth*.

19.8.6 Non-orderly Shutdown

A TPM may be implemented such that the command execution unit does not always have access to NV memory (see 37.7.2). For such an implementation, it may not be possible to increment the NV copy of *failedTries* when the authorization failure occurs. When the failure occurs, the TPM will return TPM_RC_AUTH_FAIL and, until the NV version of *failedTries* is updated, the TPM will be in lockout.

It is possible that the TPM will be reset when a write to the NV version of *failedTries* is pending. If the TPM did not handle this special case, then an attacker could try an authorization for a DA protected object when NV writes are not possible. When the TPM restarted, the failed attempt would not be recorded, and the attacker could try again.

To prevent this type of attack, at TPM2_Startup(), the TPM checks if it is starting after an orderly shutdown. If not, and *failedTries* is not already equal to *maxTries*, then the TPM will increment *failedTries* by one.

NOTE This check and increment of *failedTries* may not be necessary if it is impractical for an attacker to prevent update of the NV version of *failedTries*.

An alternative implementation sets an NV flag indicating that access to a DA protected object occurred during this boot cycle. After a non-orderly restart, if the flag is set, the TPM increments *failedTries* and clears the flag. If the flag is clear, there is no need to increment *failedTries*.

EXAMPLE This handles the case where a platform repeatedly does a non-orderly shutdown, possibly due to a low battery. Without the flag, *failedTries* would increment on each reboot and the TPM would go into lockout.

19.8.7 Justification for Lockout Due to Session Binding

When a bound session is created, the caller does not have to prove knowledge of the *authValue* of the bind object. The *authValue* is used in the creation of the *sessionKey* and if the caller does not know the *authValue*, they will not be able to compute the correct *sessionKey* and use the authorization session.

A bound authorization session may be used to authorize actions on another object. If that object does not have DA protection, then an attacker could use binding to circumvent DA protection on the bind object.

The attack is as follows:

a) An attacker creates an object (D) that has no DA protection and *authValue* known to the attacker.
b) An attacker guesses a possible *authValue* for a DA protected object (object A).
c) The attacker uses object A as the *bind* object in TPM2_StartAuthSession() to create a session (S).
d) The attacker uses session S to authorize an action on object D.
e) If the authorization fails, the attacker goes to step b) and tries a new value.

By retaining the DA state of object A in the session state, the attack is prevented. When the session is used for authorization, the authorization failure counter (*failedTries*) is incremented if either the entity being authorized is subject to DA protection or if the session is bound to an entity that has DA protection.

 Copyright © TCG 2006-2020

NOTE If a session is bound to a permanent entity other than TPM_RH_LOCKOUT, then the session is not bound to an entity that has DA protection.

19.8.8 Sample Configurations for Lockout Parameters

19.8.8.1 Introduction

Two common configurations are anticipated: one for enterprise-managed TPMs, and one for home users.

NOTE It is anticipated that the operating system will layer additional anti-hammering protection atop that provided by the TPM so that it is unlikely that one OS user will be able to interfere with the actions of another user or the trusted computing base (TCB).

19.8.8.2 Enterprise Use

In this use, it is expected that the TPM owner will set the *lockoutAuth* to a high-entropy value that is held in a database and set the *lockoutRecovery* to a small, non-zero value, such as one. The enterprise will use this value to recover the TPM when suitable non-automated validation procedures have been performed.

The enterprise would likely set *maxTries* to a relatively low value (such as, 10).

For a server or data center, the *recoveryTime* would be set to a large value (such as, 2^{32} -1) implying manual recovery. For laptops, a setting of a few hours would provide adequate protection for PINs.

19.8.8.3 Home or Unmanaged Use

In this application, the *lockoutAuth* may be set to a random, high-entropy value that is then erased so that programmatic lockout recovery is not possible. *maxTries* and *recoveryTime* can be set to balance security and convenience.

NOTE If this configuration is used, the only way to execute TPM2_Clear() to change the owner is to use Platform Authorization.

 Copyright © TCG 2006-2020

20 Audit Session

20.1 Introduction

An audit session allows for the auditing of a selected sequence of commands so that evidence may be provided that the commands were executed.

Any HMAC authorization session may be designated for auditing but only one session may be used for audit in each command. A session is designated for auditing by setting the *audit* attribute in the session.

When a session is first used as an audit session, the TPM will initialize the audit hash for the audit session. The initialization value is a Zero Digest with the number of octets determined by the hash algorithm of the session.

If the session was bound when created (see 19.6.10 and 19.6.12), the bind value is lost and any further use of the session for authorization will require that the *authValue* be used in the HMAC.

Since the first use of an audit session may cause the size of the session context to change, the command may fail due to insufficient memory. TPM-management software may save other session contexts and retry the command.

NOTE 1 The TPM is required to have sufficient memory to allow three sessions to be simultaneously loaded, one of which may be an audit session.

For all commands using a session tagged as audit (including the initial use), if the command completes successfully, the *cpHash* and the *rpHash* are Extended to the audit session digest. When a command fails, the audit session digest is not changed and, as is normal in the case of a command failure, the sessions are not included in the response and session nonces are not updated.

The equation for updating the audit session digest is:

$$auditDigest_{new} \coloneqq \mathbf{H}_{auditAlg}\left(auditDigest_{old} \,||\, cpHash \,||\, rpHash\right) \tag{30}$$

The hash algorithm is the algorithm designated in TPM2_StartAuthSession().

NOTE 2: Audit within an encrypted session will record the encrypted cpHash and/or rpHash, which is unlikely to be useful at the application level.

Unless a command description indicates that no sessions are allowed, an audit session may be used with any command. A command may have only one audit session.

An audit session uses the same session format as other HMAC-based sessions. The method of computing the HMAC differs in that, if the audit session is not associated with any object handle, no *authValue* is available for use in the authorization HMAC. All HMAC computations for an audit session will set *authValue* to an Empty Buffer.

NOTE 3 If the *sessionKey* is also an Empty Buffer, then no HMAC computation is performed and the *hmac* parameter of the session structure will be an Empty Buffer.

For commands that do not require authorization, a bound or salted audit session causes an HMAC based on a shared secret to be generated. This provides assurance that the command was executed on the TPM. A bound session allows association with a known *authValue* in a TPM, which can provide assurance that the commands being audited are actually associated with a specific TPM. However, if others know the *authValue*, then the unsalted audit session may have the same association issue as the unbound session. A salted session can be associated with a key that is known to be TPM-resident, so the audit based on a salted session can be reliably associated with a specific TPM.

 Copyright © TCG 2006-2020

NOTE 4 This assurance does not require a signed audit digest to be used.

EXAMPLE TPM2_PCR_Read does not require authorization. A bound or salted audit session will cause an HMAC to be used, and thus provide integrity for the command and response.

20.2 Exclusive Audit Sessions

An exclusive audit session permits the TPM to prove that a series of commands were executed with no intervening commands that were not audited by the exclusive audit session.

In a response, the *auditExclusive* attribute of an audit session will indicate if the TPM has executed any commands that were not audited by the session. If there was another user of the TPM, the *auditExclusive* attribute will be CLEAR. If not, the audit session is exclusive and the *auditExclusive* attribute will be SET.

The TPM keeps track of the current exclusive session. At most, one active session may have the *auditExclusive* status. A session becomes the current exclusive audit session when it is first used as an audit session, regardless of the setting of *auditReset*. It may also become the current exclusive audit session if the *auditReset* attribute of the session is SET in the command. In the response, the *auditExclusive* attribute of the session will be SET and the session is exclusive. The session is no longer the current exclusive audit session if it is flushed (TPM2_FlushContext()) or if an auditable command is executed that does not use the current exclusive audit session.

NOTE 1 *auditReset* may only be SET if *audit* is also SET.

A command that is not allowed to have any sessions will not change the current exclusive audit session. Those commands include the context management commands (TPM2_ContextSave(), TPM2_ContextLoad(), and TPM2_Flush()), TPM2_Startup(), and TPM2_ReadClock().

NOTE 2 It is the responsibility of the TCG Software Stack (TSS) or other controlling software to preserve the integrity of the exclusive audit session. As the purpose of the exclusive audit session is to show that no other commands were executed during the session, the expectation is that the controlling software would limit access to the TPM to prevent any other uses of the TPM.

20.3 Command Gating Based on Exclusivity

If the *auditExclusive* attribute of an audit session is SET in the command, then the TPM will return TPM_RC_EXCLUSIVE if the audit session is not the current exclusive audit session.

NOTE 1 As with other error returns, no change is made to the state of the session and it remains active.

NOTE 2 *auditExclusive* in a command only determines whether the command is executed. It does not affect the exclusive status of the session.

NOTE 3 *auditExclusive* may only be SET if audit is also SET.

20.4 Audit Session Reporting

The audit status of an audit session can be determined with TPM2_GetSessionAuditDigest(). This command returns a data structure that includes the audit session digest. If the handle for the signing key is not TPM_RH_NULL, the TPM returns a signature over the data structure.

In the atypical case where the TPM2_GetSessionAuditDigest() sessionHandle is the same as the handle of the audit session, because the audit digest is signed before the audit digest is updated, the *cpHash* and *rpHash* for a TPM2_GetSessionAuditDigest() is not included in the audit digest of the signed data structure. Possession of the audit digest is proof that the command executed. However, the *cpHash* and *rpHash* of TPM2_GetSessionAuditDigest() will be included in subsequent audits if the audit session remains active.

 Copyright © TCG 2006-2020

TPM2_GetSessionAuditDigest() requires that the indicated session be an audit session and will return TPM_RC_TYPE if it is not. The TPM does not change internal state unless the command actions complete successfully. This means that a session cannot become an audit session unless the command in which it is designated as an audit session completes successfully. From this we can conclude that a session cannot be designated as being an audit session in a TPM2_GetSessionAuditDigest() in which the same session is the audited session.

20.5 Audit Establishment Failures

If a command is the first use of a session as an audit session, and the command fails, then the state of a session as an audit session will not change. This means that, if a session was not an audit session before the command was executed, it will not be an audit session after the command fails. If a session was an audit session before the command was executed, it will be an audit session after the command fails.

If a command fails, then the exclusive status of sessions does not change. A session that was exclusive before the command failure is exclusive after the command failure.

20.6 Audit Alternative

Both TPM2_GetSessionAuditDigest() and TPM2_GetCommandAuditDigest() require Endorsement Authorization. If an application does not have Endorsement Authorization, it can still obtain proof that a command was run on a particular TPM. The application must have a *fixedTPM* asymmetric encryption key that is trusted to be on the TPM. This key would have similar trust properties to the signing key that would be used with the TPM2_GetSessionAuditDigest() and TPM2_GetCommandAuditDigest() commands. The application uses an audit session that is a salted session with the trusted key specified as *tpmKey*. The salt forces an HMAC session. The HMAC verification is proof that the command was run on that TPM.

 Copyright © TCG 2006-2020

21 Session-based encryption

21.1 Introduction

Several commands have parameters that may need to be encrypted going to or from the TPM. An example is the authorization data that is passed to the TPM when an object is created or when the authorization value is changed. Session-based encryption may be used to ensure confidentiality of these parameters.

Not all commands support parameter encryption. If session-based encryption is allowed, only the first parameter in the parameter area of a request or response may be encrypted. That parameter must have an explicit size field. Only the data portion of the parameter is encrypted. The TPM should support session-based encryption using XOR obfuscation. Support for a block cipher using CFB mode is platform specific. These two encryption methods (XOR and CFB) do not require that the data be padded for encryption, so the encrypted data size and the plain-text data size is the same.

If the symmetric algorithm is TPM_ALG_NULL and encryption or decryption is specified, the TPM returns TPM_RC_SYMMETRIC.

Any first parameter may be encrypted as long as the parameter has a size field.

Session-based encryption uses the algorithm parameters established when the session is started and values that are derived from the session-specific *sessionKey*. The encryption values are created in a way that is dependent on both the session type and the session encryption parameters.

If a session is also being used for authorization, *sessionValue* (see 21.2 and 21.3) is *sessionKey* || *authValue*. The binding of the session is ignored. If the session is not being used for authorization, *sessionValue* is *sessionKey*.

NOTE 1 A policy session that is used for parameter encryption uses *authValue* to calculate *sessionValue* even if the policy does not include TPM2_PolicyAuthValue().

If *sessionAttributes.decrypt* is SET in a session in a command, and the first parameter of the command is a sized buffer, then that parameter is encrypted using the encryption parameters of the session. If *sessionAttributes.encrypt* is SET in a session of a command, and the first parameter of the response is a sized buffer, then the TPM will encrypt that parameter using the encryption parameters of the session. The *encrypt* attribute may only be SET in one session that is used in a command and the *decrypt* attribute may only be SET in one session per command. The attributes may be SET in different sessions or in the same session.

Parameters in commands are encrypted before any *cpHash* is computed. Parameters in responses are encrypted before any *rpHash* is computed.

The parameter data buffer is protected with either XOR obfuscation or CFB mode encryption. The size field of the parameter is not protected.

When a command/response with an encrypted parameter is received, the *cpHash*/*rpHash* is computed as required for the sessions before the parameter is decrypted.

NOTE 2 The caller may obfuscate the true size of an authorization value by adding octets of zero to the end. The extra octets of zero will have no impact on the authorization computations and may be discarded by the TPM.

The two methods of session-based encryption used in this specification are, by themselves, malleable. That is, an attacker can make a controlled change (bit reversal) in the encrypted data that will result in an

 Copyright © TCG 2006-2020

identical change in the decrypted data. This kind of attack is mitigated by the HMAC authorization session verification.

21.2 XOR Parameter Obfuscation

For session-based obfuscation using **XOR**(), the operation is:

$$\mathbf{XOR}(parameter, hashAlg, sessionValue, nonceNewer, nonceOlder) \quad (31)$$

where

parameter	a variable sized buffer containing the parameter to be obfuscated
hashAlg	the hash algorithm associated with the session
sessionValue	see 21.1
nonceNewer	for commands, this will be nonceCaller and for responses it will be nonceTPM
nonceOlder	for commands, this will be *nonceTPM* and for responses it will be *nonceCaller*

NOTE 1 The **XOR**() function is defined in 11.4.7.3.

NOTE 2 The obfuscated size of parameter is the same as the size of the underlying parameter. That is, if a TPM2B_CREATE is obfuscated, the size of the obfuscated data is the same as the size of the data.

21.3 CFB Mode Parameter Encryption

When session-based encryption uses a symmetric block cipher, an encryption key and IV will be generated from:

$$\mathbf{KDFa}\ (hashAlg, sessionValue, \text{“CFB”}, nonceNewer, nonceOlder, bits) \quad (32)$$

where

hashAlg	the hash algorithm associated with the session
sessionValue	see 21.1
“CFB”	label to differentiate use of **KDFa**() (see 4.2)
nonceNewer	*nonceCaller* for a command and *nonceTPM* for a response
nonceOlder	*nonceTPM* for a command and *nonceCaller* for a response
bits	the number of bits required for the symmetric key plus an IV

NOTE 1 The IV size is equal to the block size of the cipher.

The most significant octets of the returned value are used as the encryption key and the remaining octets are used as the IV. The number of octets used for the encryption key and for the IV is dependent on the algorithm parameters of the session.

EXAMPLE For AES, the block size is 16 octets regardless of the key size. If the key size were 256 bits (32 octets), then, in the call to **KDFa** (), *bits* would be set to 48*8. The most significant 32 octets of the returned value would be used as the key for the encryption and the next 16 octets would be used for the IV.

 Copyright © TCG 2006-2020

NOTE 2 If the key size is not an even multiple of 8 bits, the first N octets of the returned value will contain the key and the remaining octets the IV. N is the smallest integer such that (N * 8) ≥ the key size.

The data portion of the parameter is then encrypted using the symmetric key and the symmetric block cipher algorithm associated with the session.

 Copyright © TCG 2006-2020

22 Protected Storage

22.1 Introduction

When a Protected Object is in the TPM, it is in a Shielded Location because the only access to the context of the object is with a Protected Capability (a TPM command). The size of TPM memory may be limited and if the only storage for Protected Objects were the TPM Shielded Locations, the TPM's usefulness would be reduced. The effective memory of the TPM is expanded by using cryptographic methods for Protected Objects when they are not in Shielded Locations.

22.2 Object Protections

The cryptographic protections for a Protected Object include encryption to prevent disclosure of the confidential contents, and an integrity check to allow detection of modifications to the externally stored Protected Object. The integrity check detects modifications to either the confidential or the non-confidential portions of the Protected Object.

The integrity value is computed over the encrypted data. If the integrity check fails, then symmetric decryption will not occur. Since the integrity value contains the digest of the associated public area (its Name), the confidential contents of the Protected Object will not be decrypted if they are not properly paired with a public area.

22.3 Protection Values

The protection of a sensitive area uses two keys. These values are created from a secret value associated with an object's Storage Parent. One of the keys is used as an HMAC key and the second is a symmetric encryption key.

A seed value is used in the generation of the symmetric encryption key and the HMAC key. The source of the seed is dependent on the situation. If the protections are for an object in a hierarchy, the seed is the *seedValue* in the Storage Parent's sensitive area. If the protections are for a duplication blob, the seed is derived from a shared secret that is protected using asymmetric methods of the new parent. The algorithm-specific annexes contain the formulations for deriving the seed when asymmetric protections are used.

To produce the symmetric key, the seed value and object Name are used in **KDFa**() as shown in equation (33). This method is used when a symmetric key is generated for the protection of sensitive areas attached to a hierarchy or sensitive data in a duplication blob (see 23.3).

NOTE 1 This method is also used to generate the symmetric key used for the protection of credential values (see 24.4).

To produce the HMAC key, the seed is used in **KDFa**() as shown in equation (35). This method is used when an HMAC is used to protect the integrity of a sensitive area attached to a hierarchy or for sensitive data in a duplication blob.

NOTE 2 This method is also used to generate the HMAC key for credential values (see 24.4).

When performing symmetric encryption, an IV of zero is used unless the same symmetric key is used multiple times. The same symmetric key is used each time that the sensitive area of a child changes due to TPM2_ObjectChangeAuth(). For encryption of a child, a random IV is generated by the TPM each time it performs the encryption.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

22.4 Symmetric Encryption

A symmetric key is used to encrypt the sensitive area of an object that was created by TPM2_Create() or imported by TPM2_Import(). It is also used when re-encrypting a sensitive area when the authorization value is changed (TPM2_ObjectChangeAuth()). The symmetric key is derived from a seed value contained in the Storage Parent's sensitive area and the Name of the protected object.

The block cipher used for encrypting the object's sensitive area is the symmetric cipher of the Storage Parent.

The symmetric key for the encryption is computed by:

$$symKey \coloneqq \mathbf{KDFa}\ (pNameAlg, seedValue, \text{“STORAGE”}, name, \text{NULL}\ , bits) \tag{33}$$

where

$pNameAlg$	*nameAlg* of the object's Storage Parent
$seedValue$	symmetric seed value in the sensitive area of the object's Storage Parent (see 27.7.4)
“STORAGE”	a value used to differentiate the uses of the KDF
$name$	Name of the object being encrypted / decrypted
$bits$	number of bits required for the symmetric key

When a $symKey$ is being used to protect the sensitive area of a child object, the TPM will create a random IV value ($symIv$) that is the size of an encryption block of the symmetric algorithm. This $symIV$ is included in the private area and in the HMAC computation of the sensitive area. A *symIV* of zero is used when encrypting the sensitive area for duplication or a credential to be used in TPM2_ActivateCredential().

The $symKey$ and $symIv$ are used to encrypt the sensitive data.

$$encSensitive \coloneqq \mathbf{CFB}_{pSymAlg}\,(symKey, symIv, sensitive) \tag{34}$$

where

$\mathbf{CFB}_{pSymAlg}$	symmetric encryption in CFB mode using the symmetric algorithm of the Storage Parent
$symKey$	symmetric key from (33)
$symIv$	IV from RNG or 0
$sensitive$	a TPM2B_SENSITIVE containing the sensitive area structure being protected

NOTE The *size* and *buffer* fields of *sensitive* are encrypted.

After the data is encrypted, the TPM2B_IV containing the random $symIv$ is placed in front of the encrypted data in preparation for the integrity computation. If the *symIV* was zero, then no value is added to the encrypted data.

22.5 Integrity

The HMAC key ($HMACkey$) for the integrity is computed by:

 Copyright © TCG 2006-2020

$$HMACkey \coloneqq \mathbf{KDFa}\ (pNameAlg, seedValue, \text{“INTEGRITY”}, \text{NULL}, \text{NULL}, bits) \quad (35)$$

where

$pNameAlg$	the *nameAlg* of the object's Storage Parent
$seedValue$	the symmetric seed value in the sensitive area of the object's Storage Parent (see 27.7.4)
“INTEGRITY”	a value used to differentiate the uses of the KDF
$bits$	the number of bits in the digest produced by *pNameAlg*

$HMACkey$ is then used in the integrity computation.

An HMAC is performed over the $symIV$ and the $encSensitive$ produced in (34).

NOTE 1 This is called an *outerHMAC* because it is the same HMAC process that is used when an object is duplicated. The duplication can produce an inner and an outer HMAC.

$$outerHMAC \coloneqq \mathbf{HMAC}_{pNameAlg}\ (HMACkey, symIv \mid\mid encSensitive \mid\mid name.buffer) \quad (36)$$

where

$\mathbf{HMAC}_{pNameAlg}$	the HMAC function using *nameAlg* of the object's Storage Parent
$HMACkey$	a value derived from the Storage Parent’s symmetric protection value (*seedValue*) according to equation (35)
$symIv$	a marshaled TPM2B_IV containing the symmetric IV value used in (34). Both the size and buffer fields are included in the HMAC
$encSensitive$	encrypted TPM2B_SENSITIVE produced in (34); after encryption, the size and buffer fields are not separable
$name.buffer$	the Name of the object being protected (does not include a size field)

The integrity value is placed before the symmetric IV.

NOTE 2 Placement of the integrity value at the beginning of the sensitive area in preparation simplifies the process of finding the integrity value when the protected data contains variable-sized elements.

NOTE 3 Inclusion of the Name ensures that the sensitive area is associated with the correct public area.

</table>

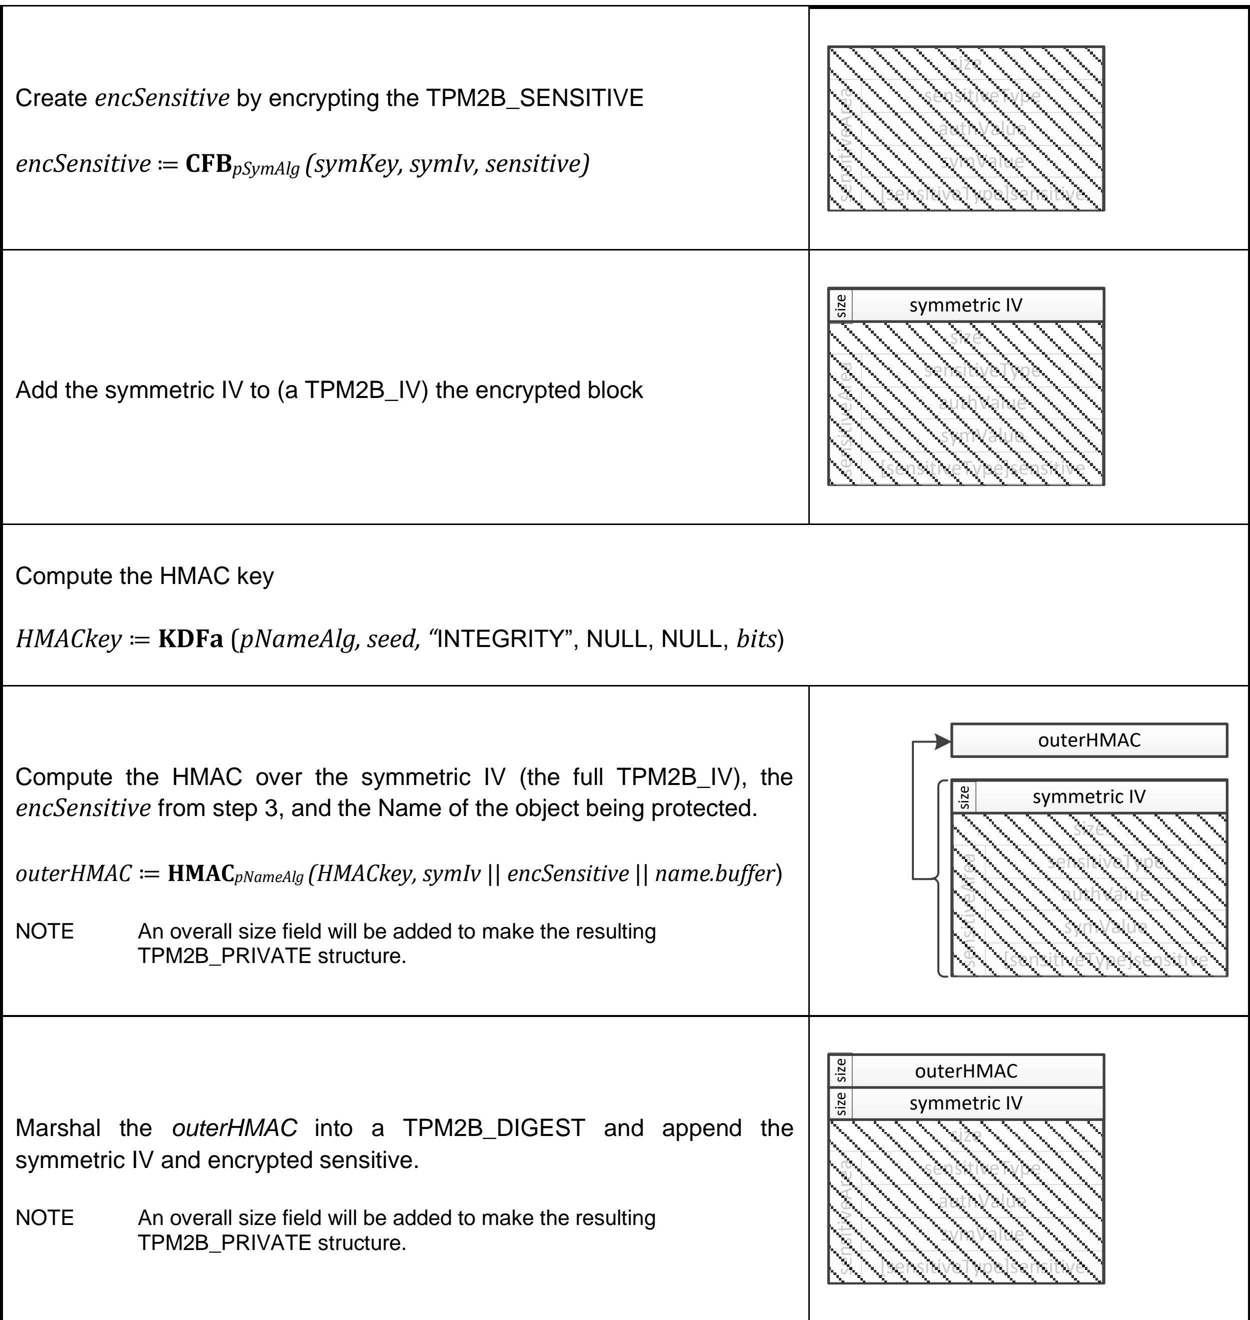

Figure 17 — Creating a Private Structure

23 Protected Storage Hierarchy

23.1 Introduction

The TPM supports the creation of hierarchies of Protected Locations. A hierarchy is constructed with Storage Keys as the connectors to which other types of objects (keys, data, and other connectors) may be attached.

The hierarchical relationship of objects allows segregation of objects based on the system-operating environment (established by PCR or authorizations) as well as simplifying the management of groups of related objects.

23.2 Hierarchical Relationship between Objects

A hierarchy is rooted in a secret seed key, kept in the TPM. To create a hierarchy of keys, the seed key (Primary Seed) is used to generate a key that uses a specific set of algorithms. If this key is a restricted decryption key, then it is a Parent Key. If it is not a Derivation Parent, then it is a Storage Parent under which other objects may be created or attached.

A Storage Parent provides protection for the sensitive area in another object (a child) when that object is stored outside of the TPM. Protection is provided by symmetric encryption and HMAC-based integrity protection of the sensitive area. There are two different cases for sensitive area encryption: storage and duplication.

When an Ordinary Object is created (TPM2_Create() or TPM2_CreateLoaded()) the keys used for protection of the Object's sensitive area are derived from a seed value (*seedValue*) in the sensitive area of the Storage Key. When an Object is prepared for duplication, its sensitive area is protected by a random key and a form of Diffie-Hellman is used to convey the key to the duplication target.

The objects in a hierarchy have a parent-child relationship. A Storage Key that is protecting other objects is a Storage Parent and the objects that it is protecting are its children. The ancestors of an object are the parent keys that connect the object to a TPM Primary Seed. Descendants of a key are all the objects that have that Parent as an ancestor. Unless it is intended to be used as a parent, a child object may be of any type.

A Derived Object is a child of its Derivation Parent. Both Primary Objects and Derived Objects are derived from seed values. For a Primary Object, the seed value is a Primary Seed and for a Derivation Object the seed value is the secret seed value in the Derivation Parent.

The sensitive part of an object created from a seed is not stored off of the TPM except in a context blobs (see clause 30). This means that the seed used to create the Object is not also used to generate protection keys for the Object. When an Object is duplicated, its sensitive area is protected by a random key, so the creation seed is not put at risk by the duplication process (see 23.3).

 Copyright © TCG 2006-2020

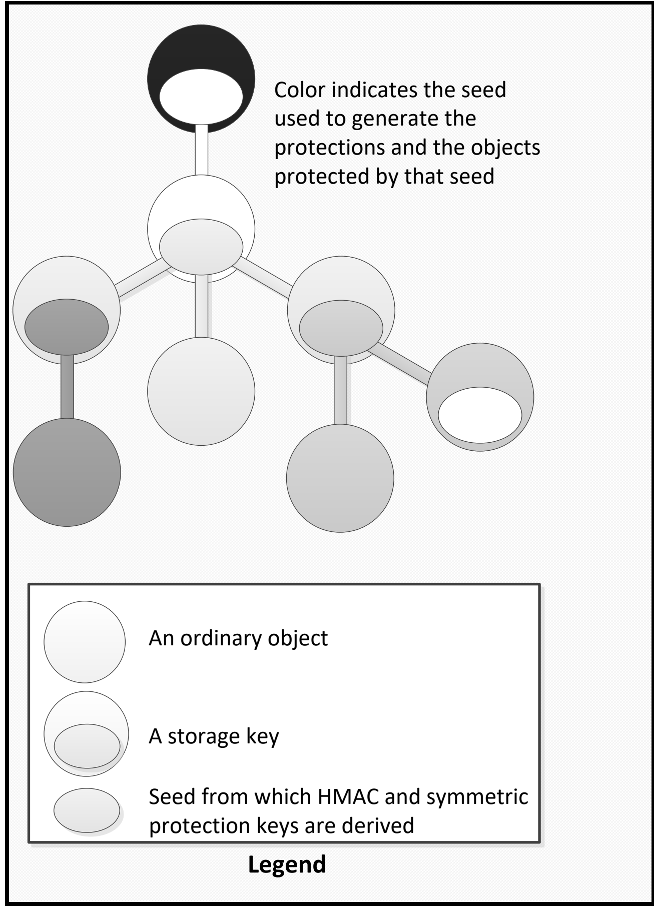

Figure 18 — Symmetric Protection of Hierarchy

There are two classes of Storage Keys: asymmetric and symmetric. All Storage Keys contain a symmetric protection key. An asymmetric Storage Key has a public identity that can be used as the target of an identity-based or secret-based duplication operation. An object that is a symmetric block cipher Object may also be a Storage Key, but may only be the target of secret-based duplication

23.3 Duplication

23.3.1 Definition

Duplication is the process of allowing an object to be a child of additional Storage Parent keys. The new parent (NP) may be in a hierarchy of the same TPM or of a different TPM.

The creator of an object controls the duplication process by selecting the duplication policy for the object.

Authorization for duplication requires a policy session. The policy sequence is required to have a command that causes the *commandCode* value of the policy context to be set to TPM_CC_Duplicate. This enables the DUP role of the policy, which is a requirement for duplication.

Duplication occurs on a loaded object and produces a new, sensitive structure that is encrypted using the methods of the NP. This new sensitive structure may not be used until TPM2_Import() has been executed to convert the object from "external" to "internal" protections.

NOTE 1 External protections use both asymmetric and symmetric cryptography, whereas the internal protections only use symmetric cryptography.

 Copyright © TCG 2006-2020

When an Object is duplicated, its sensitive area may be protected with an outer wrapper, an inner wrapper, or both. The outer wrapper uses Diffie-Hellman based on asymmetric keys and provides identity-based duplication. The inner wrapper uses a symmetric key that is under control of the duplication authority for the Object. Duplication using an inner wrapper is secret-based duplication.

NOTE 2 The duplication authority is the entity that controls the conditions under which an Object may be duplicated.

23.3.2 Protections

23.3.2.1 Introduction

In TPM2_Duplicate(), the caller may specify that the object should be protected with an inner, symmetric encryption. That is, the sensitive area is symmetrically encrypted before it is asymmetrically encrypted using the methods of the NP. If a symmetric inner wrapper is desired, the caller may provide a key or allow the TPM to generate the key.

If the *encryptedDuplication* attribute is SET in the object being duplicated, then it is required that the object have an inner wrapper and that the new parent not be TPM_RH_NULL. For such an object, the TPM will return an error (TPM_RC_SYMMETRIC) if the *symmetricAlg* parameter in TPM2_Duplicate() is TPM_ALG_NULL and TPM_RC_HIERARCHY if the *newParentHandle* parameter is TPM_RH_NULL.

Creation of a duplicate object uses two encryption phases. The first is used to apply an inner wrapper and the second is to encrypt using the algorithms of the NP.

The *encryptedDuplication* attribute of all objects in a duplication group are required to have the same setting. When an object is created with the *fixedParent* attribute CLEAR, then the *encryptedDuplication* attribute may be SET or CLEAR if the *fixedTPM* attribute is SET in the Storage Parent. If the *fixedTPM* attribute of a Storage Parent is not SET, then the *encryptedDuplication* attribute is required to be the same in all descendant objects of that Storage Parent.

23.3.2.2 Inner Duplication Wrapper

For the first phase, the TPM computes an integrity hash over the sensitive data. This hash includes the Name of the public area associated with this object.

$$innerIntegrity \coloneqq \mathbf{H}_{nameAlg}(sensitive \mid\mid name) \tag{37}$$

where

$\mathbf{H}_{nameAlg}$	hash function using the *nameAlg* of the object
$sensitive$	a TPM2B_SENSITIVE
$name$	the Name of the object being protected

A TPM2B_DIGEST containing the integrity digest value is prepended to the sensitive area and the buffer (integrity plus sensitive) is encrypted using CFB.

$$encSensitive \coloneqq \mathbf{CFB}_{pSymAlg}(symKey, 0, innerIntegrity \mid\mid sensitive) \tag{38}$$

where

$\mathbf{CFB}_{symAlg}$	symmetric encryption in CFB mode using the algorithm specified in the command

 Copyright © TCG 2006-2020

$symKey$	*encryptionKeyIn* parameter in TPM2_Duplicate() or a value from the RNG if no key is provided
$innerIntegrity$	value from (37)
$sensitive$	the sensitive value used in (37)

If no inner wrapper is specified, no integrity value is computed, and no encryption occurs in this first phase and

$$encSensitive \coloneqq sensitive \tag{39}$$

23.3.2.3 Outer Duplication Wrapper

In the second phase, the $encSensitive$ produced by phase 1 is encrypted and integrity checked using processes similar to those defined in clause 22. However, the seed from which the protection keys are derived is protected by the asymmetric algorithm of the NP. The method of generating *seed* is determined by the asymmetric algorithm of the NP. The different methods are described in annexes to this TPM 2.0 Part 1, for example, B.10.3 or C.6.3. The seed is selected prior to integrity generation for *encSensitive* or encryption of *encSensitive*.

NOTE For an RSA new parent, *seed* is not allowed to be larger than the size of the digest produced by the *nameAlg* of the object. When the TPM creates *seed*, it will be exactly the size of the *nameAlg* of the new parent.

Given a value for $seed$, a symmetric encryption key ($symKey$) is created by:

$$symKey \coloneqq \mathbf{KDFa}\,(npNameAlg, seed, \text{“STORAGE”}, Name, \text{NULL}, bits) \tag{40}$$

where

$npNameAlg$	the *nameAlg* of the new parent
$seed$	the symmetric seed value
“STORAGE”	a value used to differentiate the uses of the KDF
$Name$	the Name of the object being encrypted or decrypted
$bits$	the number of bits required for the symmetric key

The $symKey$ is used to encrypt the $encSensitive$.

$$dupSensitive \coloneqq \mathbf{CFB}_{npSymAlg}\,(symKey, 0, encSensitive) \tag{41}$$

where

$\mathbf{CFB}_{npSymAlg}$	symmetric encryption in CFB mode using the algorithm of the new parent
$symKey$	symmetric key from (40)
$encSensitive$	value from either (38) or (39)

 Copyright © TCG 2006-2020

Next, an HMAC key is generated from seed:

$$HMACkey \coloneqq \mathbf{KDFa}\,(npNameAlg, seed, \text{“INTEGRITY”}, \text{NULL}, \text{NULL}, bits) \tag{42}$$

where

$npNameAlg$	the *nameAlg* of the object's new parent
$seed$	the symmetric seed value used in (40)
“INTEGRITY”	a value used to differentiate the uses of the KDF.
$bits$	the number of bits in the digest produced by *npNameAlg*

An HMAC is then generated over the *dupSensitive* data. The Name of the associated public area is included in the HMAC computation to ensure that the sensitive area will only be decrypted when the proper public and private areas are used in TPM2_Import().

$$outerHMAC \coloneqq \mathbf{HMAC}_{npNameAlg}\,(HMACkey, dupSensitive\ ||\ Name) \tag{43}$$

where

$\mathbf{HMAC}_{npNameAlg}$	the HMAC function using nameAlg of the new parent
$HMACkey$	a value derived from the new parent symmetric protection value according to equation (42)
$dupSensitive$	symmetrically encrypted sensitive area produced in (41)
$Name$	the Name of the object being duplicated

To complete the duplication process, the TPM2B_PUBLIC and TPM2B_ENCRYPTED_SECRET produced by TPM2_Duplicate() are used in TPM2_Import() at the TPM containing the public and private portions of the NP. If the private area is doubly encrypted, then the symmetric key used for the inner wrapper is also given to the TPM.

TPM2_Import() will recover the symmetric key according to the algorithm of the NP. The TPM2B_PRIVATE is decrypted. If an inner wrapper is present, the TPM2B_PRIVATE is decrypted using the supplied symmetric key. After symmetric decryption, the integrity value is checked.

Marshal the $sensitive$ area into a TPM2B_SENSITIVE NOTE If no inner or outer wrapper is applied to the object, this structure is returned as the *duplicate* parameter in the response for TPM2_Duplicate().	size sensitiveArea: sensitiveType / authValue / seedValue / [sensitiveType]sensitive
Compute an $innerIntegrity$ value $innerIntegrity \coloneqq \mathbf{H}_{nameAlg}\,(sensitive\ ||\ name)$	size / innerIntegrity digest size sensitiveArea: sensitiveType / authValue / seedValue / [sensitiveType]sensitive

23.3.3 Rewrap

23.3.3.1 Introduction

TPM2_Rewrap() is a primitive of an exemplar key recovery service that performs all its security-sensitive processes on TPMs.

The effect of the recovery service is indistinguishable from duplication of a source key directly from a source platform to a destination platform.

The advantage of the recovery service is that

- registration of a source key with the recovery service relies upon an operational source platform, but not upon an operational destination platform, and
- delivery of the source key by the recovery service relies upon an operational destination platform, but not upon an operational source platform.

The recovery service keeps a source key from a source platform, irrespective of whether the destination platform is known. The source key is protected from the recovery service by virtue of a backup password that must be kept hidden from the recovery service but revealed to a destination platform. When the destination platform is revealed to the recovery service, the recovery service facilitates the installation of the source key in the destination platform.

a) While the source platform is operational, the source platform uses TPM2_Duplicate() to create a doubly wrapped duplication BLOB using a source key *TpmPrivateKey*, a backup password, and the recovery service's public key. (Duplication BLOBs are described earlier in this subclause. Note that the "Outer Duplication Wrapper" subclause explains that the outer wrapping is symmetric encryption that depends on a seed generated from a public key.)
b) While the source platform is operational, the source platform sends the duplication BLOB (Source BLOB in Figure 23) to the recovery service, which stores the BLOB.
c) When a destination platform is revealed to the recovery service, the recovery service uses TPM2_Rewrap() to derive another doubly wrapped duplication BLOB using the original doubly wrapped duplication BLOB, the recovery service's key, and the destination platform's public key.
d) When the destination platform is operational, the recovery service sends the derived duplication BLOB (Recovery BLOB in Figure 23) to the destination platform.
e) While the destination platform is operational, the destination platform uses TPM2_Import() to create a normal key BLOB from the derived duplication BLOB, the destination platform's key, and the backup password.

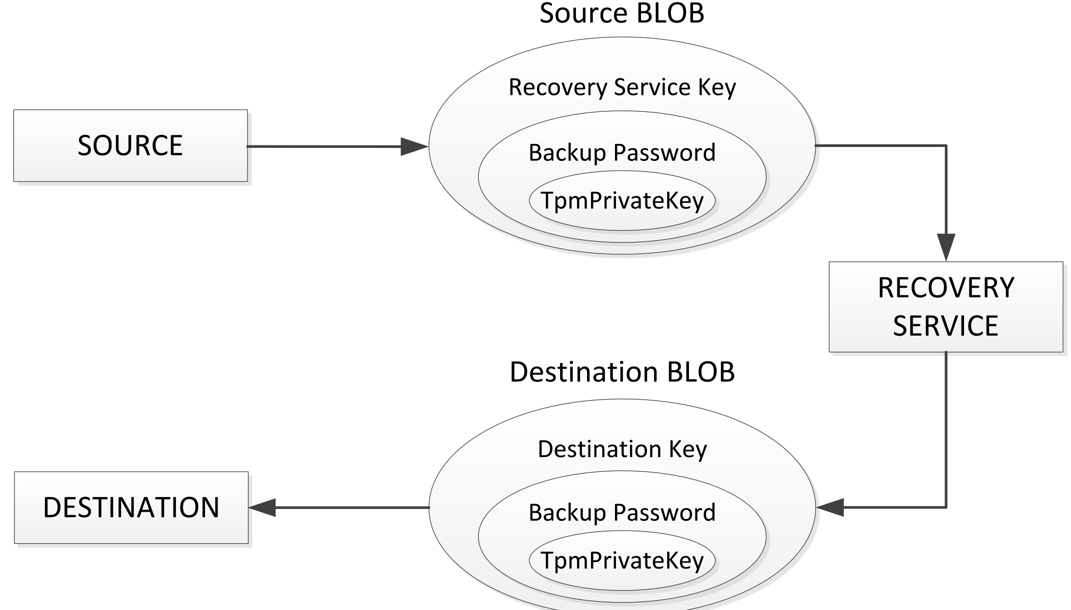

Figure 23 — Key Recovery Process

23.3.3.2 Creating a backed-up key

a) At the source platform, a key to be backed up, *sourceKey* = [*sourcePubKey* , *sourceSensitiveKey*], and the recovery service's public key *recoveryServicePubKey* are loaded in the source TPM.

b) At the source TPM, TPM2_Duplicate() is used to create the doubly wrapped duplication BLOB, which is *sourceSensitiveKey,* wrapped by *encryptionKeyIn*, wrapped by *recoveryServicePubKey*. The parameters to TPM2_Duplicate() are:

   1) *objectHandle* - references the key *sourceKey* to be sent to the recovery service

   2) *newParentHandle* - references the recovery service's public key *recoveryServicePubKey*

   3) *encryptionKeyIn* - is the backup password (this is an optional parameter and if the caller does not provide a value, the TPM will generate one)

   4) *symmetricAlg* – the encryption algorithm for the inner wrapper

c) The TPM returns:

   1) *encryptionKeyOut* – returned only if the TPM generated the key used for the inner wrapper

   2) *duplicate* – the wrapped sensitive area of *objectHandle;* the Source BLOB.

   3) *outSymSeed* - a protected version of the seed used to make the symmetric key used for outer wrapping encryption

d) The duplication BLOB duplicate is sent to the recovery service

23.3.3.3 Recovering a backed-up key

a) At the recovery service's platform, the recovery service's key *recoveryServiceKey =[recoveryServicePubKey , recoveryServiceSensitiveKey]*, and the destination platform's public key *destinationPubKey* are loaded into the recovery service's TPM.

b) At the recovery service's TPM, TPM2_Rewrap() is used to is used to replace the outer wrapper of the Source BLOB with an outer wrapper tied to the Destination Key *destinationPubKey*. The parameters for TPM2_Rewrap() are:

   1) *oldParent* - references the recovery service's key *recoveryServiceKey*

   2) *newParent* – references the destination platform's public key *destinationPubKey*

   3) *induplicate* – the Source BLOB

   4) *inSymSeed* - this is *outSymSeed* from the source platform. It is needed to derive the symmetric key used by the source platform for outer wrapping encryption

c) At the recovery service, the TPM will return

   1) *outDuplicate* – the rewrapped Destination BLOB

   2) *outSymSeed* - a protected version of the seed used to make the symmetric key used by the recovery service for outer wrapping encryption

d) At the destination platform, the destination platform's key *destinationKey =[destinationPubKey , destinationSensitiveKey]* is loaded into the TPM.

e) At the destination platform, TPM2_Import() is used to create *outPrivate* , which is a normal key BLOB that may be loaded into the TPM on the platform. The parameters to TPM2_Import() are:

   1) *parentHandle* – a reference to the destination platform's key (this will become the Storage Parent for the imported object)

   2) *encryptionKey* – the backup password (*encryptionKeyIn* or *encryptionKeyOut*)

   3) *objectPublic* – the public area of the key being imported

   4) *duplicate* – the Destination BLOB *outDuplicate* from the recovery service

   5) *inSymSeed* is *outSymSeed* from the recovery service. It is needed to derive the symmetric key used by the recovery service for outer wrapping encryption

 Copyright © TCG 2006-2020

f) At the destination platform, the TPM returns

1) *outPrivate* – the sensitive area of the imported object

23.4 Duplication Group

The duplication process allows an object or segment of a hierarchy to be duplicated for use in another hierarchy. This ability facilitates key distribution and backup. A duplication group is a group of objects in a hierarchy under a duplication root. The entire duplication group may be moved to another hierarchy by duplicating the duplication root.

When an object is created, its duplication attribute (*fixedParent*) is selected. If *fixedParent* is CLEAR, then the object may be operated on by TPM2_Duplicate(). This command allows the sensitive area of an object to be encrypted under a new parent so that it may be used in a different TPM hierarchy. The act of duplicating a Storage Key has the side effect of duplicating all of its descendants regardless of the setting of their *fixedParent* attribute. That is, if a Storage Parent is usable in a different hierarchy, then all the descendants of the Storage Parent are also usable in the different hierarchy as well.

NOTE 1 No modification of the encryption of a child object is required to make it usable on another hierarchy. This is because the Storage Key that is duplicated contains the information used to protect its children. Duplication of the protection information has the effect of duplicating the objects protected by that information.

NOTE 2 If a particular Storage Parent is usable in multiple hierarchies, then descendants of that Storage Parent are usable in the same hierarchies regardless of when they are created. That is, if they are created after the duplication of the Storage Parent, they are still usable in multiple hierarchies.

If an object has *fixedParent* CLEAR, it is the root of a duplication group. If the object is not a Storage Key, then the group will have a single member. For a Storage Key, the duplication group consists of all objects that are duplicated as a direct consequence of duplicating the group root.

Objects that have *fixedParent* SET cannot be directly duplicated (that is, they may not be the referenced *objectHandle* in TPM2_Duplicate()). However, they can be implicitly duplicated if an ancestor has *fixedParent* CLEAR and that ancestor is duplicated.

Objects that have *fixedParent* SET and have no ancestors with *fixedParent CLEAR* are the only objects that are not part of a duplication group. These objects are identified by having their *fixedTPM* attribute SET. All objects that are in a duplication group have their *fixedTPM* attribute CLEAR.

An object may be a member of more than one duplication group. This would occur if more than one of its ancestor Storage Keys has *fixedParent CLEAR* or if an object and one of its ancestors has *fixedParent* CLEAR.

 Copyright © TCG 2006-2020

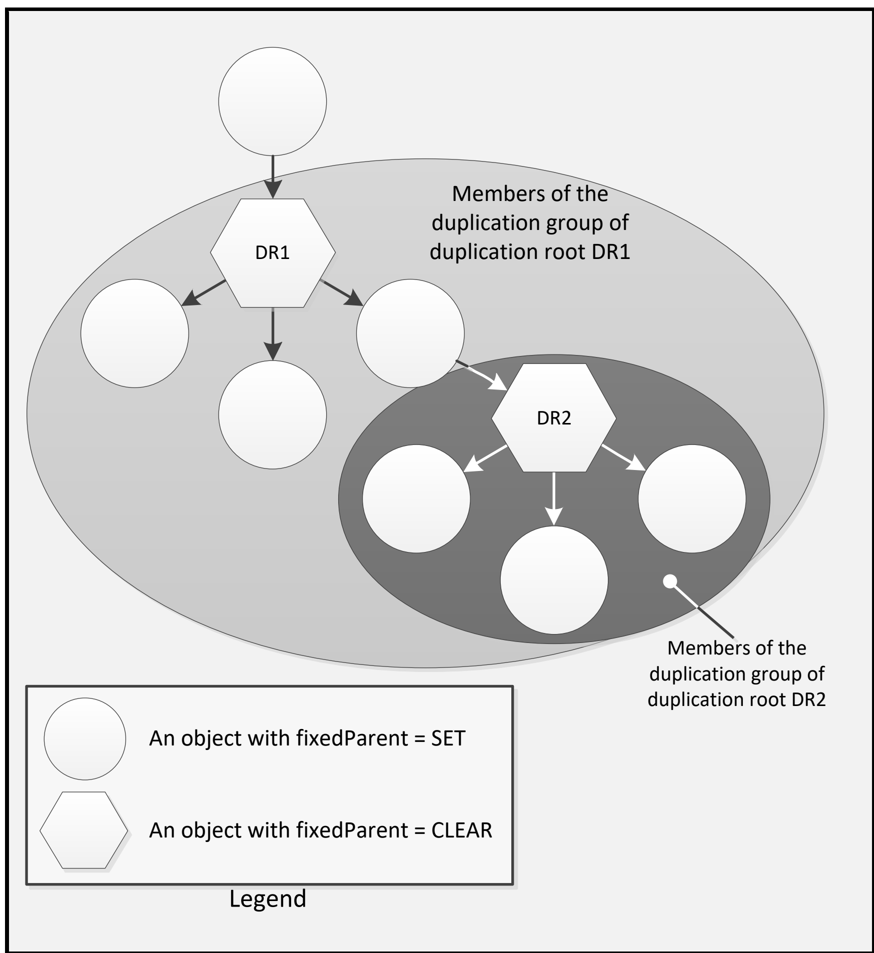

Figure 24 — Duplication Groups

23.5 Protection Group

The algorithms (asymmetric, symmetric, and hash) and key sizes used to protect child keys are consistent within a protection group. The protection group is all of the descendants of a duplication root not including other duplication roots or their descendants.

By requiring all of the non-duplicable Storage Keys to use the same algorithm, it is easier to determine the security properties of a hierarchy. If an object's *fixedTPM* attribute is SET, then all of the ancestor keys of that object use the same set of algorithms. If an object's *fixedTPM* is not SET, then the protections are determined by the duplication authority for each of the duplication roots in the object's hierarchy.

The reason that the protections are determined by the duplication authority and not by the algorithms of the key is that a duplication authority can attach a duplication root to a software-generated new parent. Inspecting the hierarchy in which an object exists does not guarantee the protections of the object unless the object's *fixedTPM* is SET.

Change of the algorithm set at a duplication root is illustrated in Figure 25.

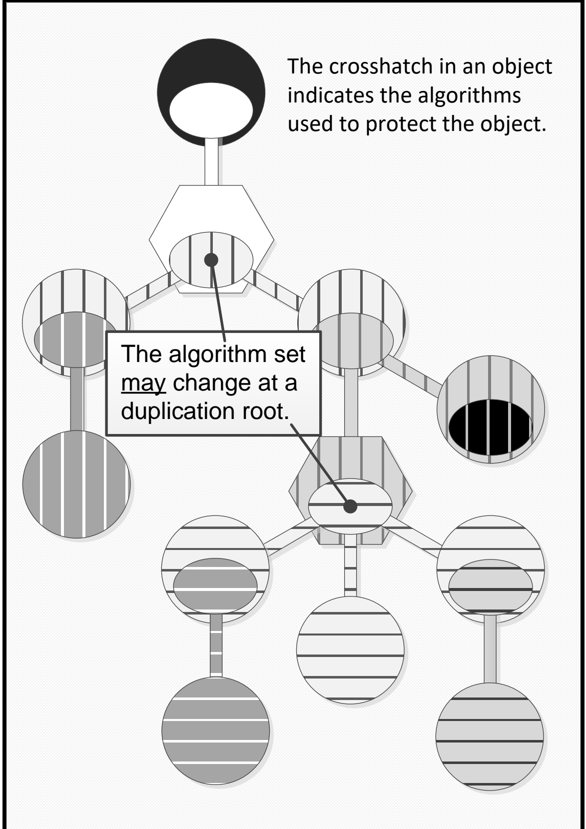

Figure 25 — Protection Groups

23.6 Summary of Hierarchy Attributes

The hierarchy attributes of an object indicate how the object is connected to the hierarchy. They indicate if the object could be extant in other hierarchies and if the object may be duplicated directly by TPM2_Duplicate().

Table 22 lists the possible combinations of an object's hierarchy attributes and the interpretation of each combination.

Table 22 — Mapping of Hierarchy Attributes

fixedParent	***fixedTPM***	**Description**
0	0	This combination represents a duplication root.
0	1	This combination is not allowed.
1	0	This combination indicates an object that is permanently in the protection group of its Storage Parent. It cannot be the *objectHandle* reference in TPM2_Duplicate().
1	1	This combination indicates an object that was created on a specific TPM and no duplicate of the object is possible.

 Copyright © TCG 2006-2020

23.7 Primary Seed Hierarchies

A Primary Object is an object that is derived from a Primary Seed value. The sensitive area of a Primary Object is not returned in the TPM2_CreatePrimary() or TPM2_CreateLoaded() response. The Primary Object will need to be regenerated each time it is needed, or it can be made persistent in NV memory on the TPM (TPM2_EvictControl()).

NOTE 1 A Primary Object may be duplicated in which case its sensitive area will be stored off of the TPM.

NOTE 2 The reason for not allowing a Primary Object to be returned is to prevent certain types of power analysis attacks on the primary seed values.

Once created, a Primary Object may be context-saved/restored.

A Primary Object may have *fixedParent* SET or CLEAR. If a Primary Object has *fixedParent* SET, then *fixedTPM* is required to be SET.

Hierarchy Attributes Settings Matrix

Table 23 shows the combinations of hierarchy settings allowed for an object. In the table, the check marks ("✓") indicate that the combination is allowed.

Table 23 — Allowed Hierarchy Settings

***fixedTPM* setting in**		**Object's *fixedParent***		
parent	**object**	**CLEAR**	**SET**	**Comments**
CLEAR	CLEAR	✓	✓	if the parent's fixedTPM attribute is CLEAR, the child's fixedTPM is required to be CLEAR
CLEAR	SET			
SET	SET		✓	if the parent of an object has fixedTPM SET, then fixedParent and fixedTPM must have the same setting in the child(1)(2)
SET	CLEAR	✓		

NOTE

1) For purposes of this table, the parent of a Primary Object is considered to have a *fixedTPM* attribute that is always SET.

2) If the parent has fixedTPM SET, then a child may be duplicable (*fixedParent* == CLEAR) or not (*fixedParent* == SET). If the child is not duplicable, then it is required to have the same setting of *fixedTPM* as its parent.

The consistency of the hierarchy settings is checked in object templates (TPM2_Create() and TPM2_CreatePrimary()) and in public areas for loaded objects (TPM2_Load()) or duplicated objects (TPM2_Import()).

24 Credential Protection

24.1 Introduction

The TPM supports a privacy preserving protocol for distributing credentials for keys on a TPM. The process allows a credential provider to assign a credential to a TPM object, such that the credential provider cannot prove that the object is resident on a particular TPM, but the credential is not available unless the object is resident on a device that the credential provider believes is an authentic TPM.

24.2 Protocol

The initiator of the credential process will provide, to a credential provider, the public area of a TPM object for which a credential is desired along with the credentials for a TPM key (usually an EK). The credential provider will inspect the credentials of the “EK” and the properties indicated in the public area to determine if the object should receive a credential. If so, the credential provider will issue a credential for the public area.

The credential provider may require that the credential only be useable if the public area is a valid object on the same TPM as the “EK.” To ensure this, the credential provider encrypts a challenge and then "wraps" the challenge encryption key with the public key of the “EK.”

NOTE “EK” is used to indicate that an EK is typically used for this process but any storage key may be used. It is up to the credential provider to decide what is acceptable for an “EK.”

The encrypted challenge and the wrapped encryption key are then delivered to the initiator. The initiator can decrypt the challenge by loading the “EK” and the object onto the TPM and asking the TPM to return the challenge. The TPM will decrypt the challenge using the private “EK” and validate that the credentialed object (public and private) is loaded on the TPM. If so, the TPM has validated that the properties of the object match the properties required by the credential provider and the TPM will return the challenge.

This process preserves privacy by allowing TPM objects to have credentials from the credential provider that are not tied to a specific TPM. If the object is a signing key, that key may be used to sign attestations, and the credential can assert that the signing key is on a valid TPM without disclosing the exact TPM.

A second property of this protocol is that it prevents the credential provider from proving anything about the object for which it provided the credential. The credential provider could have produced the credential with no information from the TPM as the TPM did not need to provide a proof-of-possession of any private key in order for the credential provider to create the credential. The credential provider can know that the credential for the object could not be in use unless the object was on the same TPM as the “EK”, but the credential provider cannot prove it.

24.3 Protection of Credential

The credential blob (which typically contains the information used to decrypt the challenge) from the credential provider contains a value that is returned by the TPM if the TPM2_ActivateCredential() is successful. The value may be anything that the credential provider wants to place in the credential blob but is expected to be simply a large random number.

The credential provider protects the credential value (CV) with an integrity HMAC and encryption in much the same way as a credential blob. The difference is, when *seed* is generated, the label is “IDENTITY” instead of “DUPLICATE”.

 Copyright © TCG 2006-2020

24.4 Symmetric Encrypt

A seed is derived from values that are protected by the asymmetric algorithm of the “EK”. The methods of generating the seed are determined by the asymmetric algorithm of the “EK” and are described in an annex to this TPM 2.0 Part 1. In the process of creating *seed*, the label is required to be “INTEGRITY.”

NOTE If a duplication blob is given to the TPM, its HMAC key will be wrong and the HMAC check will fail.

Given a value for *seed*, a key is created by:

$$symKey \coloneqq \mathbf{KDFa}\ (ekNameAlg, seed, \text{“STORAGE”}, name, \text{NULL}, bits) \tag{44}$$

where

ekNameAlg	the *nameAlg* of the key serving as the “EK”
seed	the symmetric seed value produced using methods specific to the type of asymmetric algorithms of the “EK”
“STORAGE”	a value used to differentiate the uses of the KDF
name	the Name of the object associated with the credential
bits	the number of bits required for the symmetric key

The *symKey* is used to encrypt the CV. The IV is set to 0.

$$encIdentity \coloneqq \mathbf{CFB}_{ekSymAlg}\ (symKey, 0, CV) \tag{45}$$

where

$CFB_{ekSymAlg}$	symmetric encryption in CFB mode using the symmetric algorithm of the key serving as “EK”
symKey	symmetric key from (44)
CV	the credential value (a TPM2B_DIGEST)

24.5 HMAC

A final HMAC operation is applied to the *encIdentity* value. This is to ensure that the TPM can properly associate the credential with a loaded object and to prevent misuse of or tampering with the CV.

The HMAC key (*HMACkey*) for the integrity is computed by:

$$HMACkey \coloneqq \mathbf{KDFa}\ (ekNameAlg, seed, \text{“INTEGRITY”}, \text{NULL}, \text{NULL}, bits) \tag{46}$$

where

ekNameAlg	the *nameAlg* of the target “EK”
seed	the symmetric seed value used in (44); produced using methods specific to the type of asymmetric algorithms of the “EK”
“INTEGRITY”	a value used to differentiate the uses of the KDF

$bits$	the number of bits in the digest produced by *ekNameAlg*

NOTE Even though the same value for label is used for each integrity HMAC, *seed* is created in a manner that is unique to the application. Since *seed* is unique to the application, the HMAC is unique to the application.

$HMACkey$ is then used in the integrity computation.

$$identityHMAC \coloneqq \mathbf{HMAC}_{ekNameAlg}(HMACkey, encIdentity \,||\, Name) \tag{47}$$

where

$\mathbf{HMAC}_{ekNameAlg}$	the HMAC function using *nameAlg* of the “EK”
$HMACkey$	a value derived from the “EK” symmetric protection value according to equation (46).
$encIdentity$	symmetrically encrypted sensitive area produced in (45)
$Name$	the Name of the object being protected

The integrity structure is constructed by placing the *identityHMAC* (size and hash) in the buffer ahead of the *encIdentity*.

24.6 Summary of Protection Process

Marshal the CV into a TPM2B_DIGEST	size | Credential Value
Using methods of the asymmetric “EK”, create a *seed* value	
Create a symmetric key for encryption: $symKey \coloneqq \mathbf{KDFa}$ ($ekNameAlg, seed,$ “STORAGE”, $Name$, NULL , $bits$)	
Create $encIdentity$ by encrypting the CV $encIdentity \coloneqq \mathbf{CFB}_{ekSymAlg}(symKey, 0, CV)$	
Compute the HMAC key $HMACkey \coloneqq \mathbf{KDFa}$ ($ekNameAlg, seed$, “INTEGRITY”, NULL, NULL, $bits$)	
Compute the HMAC over the $encIdentity$ from step 4 $outerHMAC \coloneqq \mathbf{HMAC}_{ekNameAlg}(HMACkey, encIdentity \,||\, Name)$	size | outerHMAC

Figure 26 — Creating a Identity Structure

25 Object Attributes

25.1 Base Attributes

25.1.1 Introduction

Three attributes are used to determine how the TPM may use an object. These attributes are designated as *restricted*, *sign*, and *decrypt*. The Boolean combinations of these attributes are used to express the full range of behaviors for objects.

25.1.2 *Restricted* Attribute

When the *restricted* attribute of a key is SET, the key may only operate on other objects that follow strict, but simple, format rules. A restricted key is not usable in all commands that use a key of that type. The restrictions on each type of key are explained in the clauses describing the *sign* and *decrypt* attributes.

The *restricted* attribute has no meaning when applied to an object that has both *sign* and *decrypt* CLEAR and *restricted* is required to be CLEAR for those objects.

25.1.3 *Sign* Attribute

This attribute may apply either to symmetric or asymmetric keys. A signing key uses its sensitive area key to sign data. The signature is returned by the TPM.

An asymmetric signing key may perform signing according to the key family (such as, RSA or ECC) and the signing method selected. An external entity may use the public portion of an asymmetric key to validate that the information was signed by someone with knowledge of the private portion of the key.

For a symmetric cipher object, this attribute and the object's mode determines whether the key can encrypt or sign (SMAC).

A symmetric key that can sign is used for performing an HMAC or an SMAC computation. This signature can be checked by another entity that knows the HMAC or SMAC secret key in order to validate the source of the information.

A restricted signing key may only sign a digest that has been produced by the TPM. The digest may be over externally supplied data or an internally generated structure. An internally generated structure that is to be signed will have the characteristic TPM_GENERATED_VALUE as the first octets in the structure to be hashed and signed. When the TPM generates a digest over externally provided data, the TPM validates that the first octets of the data are not equal to the TPM_GENERATED_VALUE. When a digest is signed by a restricted signing key, there is no ambiguity about whether or not the signed data was generated by the TPM.

A restricted signing key is occasionally referred to in this specification as an Attesting or Attestation Key.

25.1.4 *Decrypt* Attribute

An asymmetric decryption key uses the private asymmetric key in its sensitive area to decrypt data blobs that have been encrypted using the public portion of the key. A symmetric decryption key uses the key in its sensitive area to decrypt data that has been encrypted by that key.

A key that has both *decrypt* and *restricted* attributes SET only accepts data that has a specific structure. The encrypted data block must have as its first element an integrity value for the remainder of the

 Copyright © TCG 2006-2020

structure. This integrity value is an HMAC of the encrypted data. This format allows the TPM to prevent misuse of the restricted decryption keys that are the basis of the protected storage hierarchy.

If the sensitive data is part of a child object, the symmetric and HMAC keys are derived from the symmetric seed value (*seedValue*) in the sensitive area of the Storage Parent. If the sensitive data is a duplication or certification blob, the symmetric and HMAC keys are derived from a single use seed. That seed is then protected using the asymmetric public key of the intended recipient of the protected blob.

When loading a protected blob, the TPM validates the integrity value before decrypting the data. The only way that the integrity value can be correct is if it were created by some entity with access to the unencrypted sensitive data.

NOTE The specific threat scenario that is addressed by this scheme is that an attacker will use a protected blob in a command that is not appropriate for that blob. For example, an attacker may load the sensitive portion of an asymmetric key and attempt to access the sensitive area using TPM2_Unseal(). The TPM will unseal data, but not a key. The attacker may attempt to modify the public area of the key in order to trick the TPM into thinking that the protected blob contains a sealed data rather than a private key. The integrity value prevents these deceptions.

A restricted decryption key is often referred to in this specification as a Storage Key.

 Copyright © TCG 2006-2020

25.1.5 Uses

Table 24 shows the combinations of an object's functional attributes and describes the resulting properties.

Table 24 — Mapping of Functional Attributes

sign	*decrypt*	*restricted*	Description
0	0	0	A data blob. Can be accessed using TPM2_Unseal(). NOTE: This attribute set may only be used for a *keyedHash* object.
0	0	1	Not allowed. The TPM will not load or create an object with this setting.
0	1	0	A key that can be used in any operation that requires a decryption key, except that the key may not be a storage key.
0	1	1	Indicates that only the default schemes and modes of the key may be used In this specification, key with these properties is referred to as a Parent Key. Asymmetric keys and symmetric keys with these attributes are Storage Parents, and *keyedHash* objects with these attributes are Derivation Parents. The TPM only allows keys with these attributes to be used on objects that have a specific structure. For Storage Parents, use includes create, load, and activate credential.
1	0	0	Indicates a key that may be used with any signing operation including quote, certify, and sign. The recipient of signatures generated by this key should be aware that quotes and certifications can be forged so the trust would not be in the key but in the entity that knows the key authorization value. If use with object type TPM_ALG_KEYEDHASH, then the key may be used for HMAC operations.
1	0	1	This combination indicates a key that can sign any digest that the TPM has created. The TPM only signs a digest over externally provided data that did not have as its first octets TPM_GENERATED_VALUE. This key can be used reliably for quoting, certifying, and signing. No signing command is prohibited for this type of key. Only the default schemes and modes of the object may be used.
1	1	0	A general-purpose key that can be used with any command that requires a key as long as the command is compatible with the key algorithm. However, this key may not be a Storage Key (the parent of other keys).
1	1	1	This type of key is currently not supported because use of a signing key as a storage node could prevent an application from being able to use the TPM in a way that is compliant with FIPS.

Table 25 shows the correspondence between the TPM 1.2 method of identifying key properties and the method in this specification.

Table 25 — TPM 1.2 Correspondence

TPM 1.2 Name	sign	decrypt	restricted	Comments
TPM_KEY_SIGNING	1	0	0	In TPM 1.2, keys had restricted schemes. In this specification, the scheme is defined in the command.
TPM_KEY_STORAGE	0	1	1	The functional properties are nearly the same as TPM 1.2. This key could only be used to protect and unprotect items in a Protection hierarchy.
TPM_KEY_IDENTITY	1	0	1	In TPM 1.2, an Identity key was highly constrained and could not, for example, sign a structure that was not produced by the TPM. In this specification, the restricted signing key can sign (within the limits defined in clause 25.1.3) a digest produced by the TPM. This allows, for example, an Attestation Key to sign a PKCS#10 certificate request.
TPM_KEY_AUTHCHANGE	-	-	-	This is not used in this specification and its use was deprecated in TPM 1.2. The functionality is provided by session encryption.
TPM_KEY_BIND	0	1	0	Functionality is roughly equivalent between the TPM 1.2 type and the unrestricted decryption key. The specification would use TPM2_RSA_Decrypt() in place of the TPM 1.2 TPM_Unbind().
TPM_KEY_LEGACY	1	1	0	Use of these keys is only constrained by the key family properties. For example, an ECC key will not perform TPM2_RSA_Decrypt().
TPM_KEY_MIGRATE	0	1	1	A Storage Key may be the object of a re-wrap if the new parent is allowed within the policy for the object. The policy for duplication of the object is always visible in the public area.
Sealed Data				A blob containing user defined data

25.2 Other Attributes

25.2.1 fixedTPM and fixedParent

These attributes are described in detail in clause 23.

25.2.2 stClear

This attribute indicates an object that will need to be reloaded after any Startup(CLEAR). Objects may be loaded into the TPM and their context saved by the TPM resource manager. Normally, these saved contexts may be reloaded at any time before the next TPM Reset. However, if this attribute is SET, then the saved context associated with the object will be invalidated on each TPM Restart as well as on TPM Reset.

An object that has this attribute SET may not be made persistent.

 Copyright © TCG 2006-2020

25.2.3 sensitiveDataOrigin

The meaning and allowed settings for this attribute are different for Created and Derived Objects. For a Derived Object, this attribute is required always to be CLEAR. For a Created Object, this attribute is SET if the sensitive data of the object is to be generated by the TPM.

NOTE 1 The reason that *sensitiveDataOrigin* is to be CLEAR for a derived object is that it is impractical to use it to indicate anything about the provenance of the seed value used in deriving an object. The only case in which the *sensitiveDataOrigin* of the Derivation Parent might reasonably be reflected in the derived key is when *sensitiveDataOrigin* and *fixedTPM* are both SET in the parent. For all other cases, there is no way for the TPM to provide any assurance about the setting of *sensitiveDataOrigin.* However, for a derived key with fixedTPM SET, it is a relatively simple matter to check the setting of this attribute in the Derivation Parent. Rather than add to the TPM the complexity of validating that a Derivation Parent has the correct combination of attributes to allow this attribute to be SET, it was decided to require that this attribute be CLEAR rather than ignored. This is because this attribute does not change the way that Object derivation takes place as it does with Object creation.

When a symmetric object (TPM_ALG_KEYEDHASH or TPM_ALG_SYMCIPHER) is created, the caller may provide the secret data or have the TPM generate it. If the TPM is to be the source of the data, then the caller will SET this attribute. Otherwise, this attribute will be CLEAR, and the caller-provided data will be used.

When an asymmetric object is created, this attribute must be SET. The public part of an asymmetric object is determined by its private key. If the caller has control over both the public and sensitive areas, then the TPM cannot ensure that the key is statistically unique. This is not an issue unless the object also has *fixedTPM* SET. One of the assumptions of a *fixedTPM* object is that it is statistically unique. This would not be the case for an asymmetric key if the caller provided the data. To avoid the possibility of creating a *fixedTPM* object on multiple TPMs, an asymmetric key is required to have its private key generated by the TPM or the object may be imported. If it is imported, *fixedTPM* will not be SET.

“NOTE 2 The requirement that *sensitiveDataOrigin* be SET for asymmetric objects is enforced indirectly. When an asymmetric key is created, the caller is not allowed to provide the sensitive data of the key. Because the caller does not provide the sensitive data, *sensitiveDataOrigin* is required to be SET. Since this relationship is only checked when the object is created, *sensitiveDataOrigin* is allowed to have any setting when an object is loaded or imported.

25.2.4 userWithAuth

This attribute indicates that the object's *authValue* may be used to provide the USER role authorizations for the object. If this attribute is CLEAR, then USER role authorizations may only be provided by satisfying the object's *authPolicy* in a policy session. A policy session may be used for USER mode authorizations when this attribute is SET or CLEAR.

25.2.5 adminWithPolicy

This attribute indicates that authorization for an action requiring the ADMIN role requires that the *authPolicy* of the object be satisfied. If this attribute is CLEAR, then the *authValue* may be used in an HMAC session to perform operations that require ADMIN role.

As with USER role authorizations, any ADMIN role action may be authorized with a policy session that satisfies the *authPolicy*.

The primary reason for having a set of operations that require ADMIN role is to allow each of the actions to be individually controlled. When a policy is used for an ADMIN role action, the policy must contain a command that sets the *commandCode* for the policy to the specific command. This allows each ADMIN role action to be individually enabled and controlled without having to group them.

 Copyright © TCG 2006-2020

25.2.6 noDA

If this attribute is SET in an object, then authorization failures of the object will not invoke dictionary attack protections. In addition, actions on an object with this attribute SET are not subject to lockout. This attribute is used to ensure that access to objects used by the OS is not blocked due to actions by users. An OS would be expected either to use objects with well-known values or to use high-entropy authorization values. In neither case is dictionary attack protection required.

25.2.7 encryptedDuplication

If this attribute is CLEAR, then an object may be duplicated with *newParentHandle* set to TPM_RH_NULL, which means that there is no outer wrapper for the object. If the caller does not specify an inner wrapper, then the object may be exported with this sensitive area in the clear.

While the entity that controls duplication is expected to be trusted to maintain the confidentiality of the sensitive area of a key during duplication, conformance to some standards requires that the sensitive area be encrypted when it leaves the TPM and reliance on the caller is not adequate for those standards. This attribute provides a method of producing objects that conform to those standards.

NOTE It is understood that the duplication authority can still arrange to have access to the sensitive area of the key by creating a software key and having the TPM duplicate to that key.

26 Object Structure Elements

26.1 Introduction

The TPM is intended to provide a means of creating a Storage hierarchy to protect data and keys (keys generated by the TPM or some other entity). Each of these objects (keys and data) has two components. The first is a public area that contains the attributes of the object and a public identity. The second is the sensitive area that contains the elements of the object that require TPM protections. These elements include an authorization value, one or more secret key values, and, in some cases, sealed data values.

The structure definitions for both the public and sensitive areas of an object define how the information is to be arranged when it crosses the TPM interface. The organization of these structures as they exist within the TPM is at the discretion of the TPM vendor. However, the actions of commands in this specification are defined in terms of these presumptive structures and any implementation will need to produce equivalent results.

26.2 Public Area

The public area contains the information for identification of an object and its properties. The fields of the public are listed and described in Table 26.

Table 26 — Public Area Parameters

Parameter	Description
type	This identifies the type of the object. An algorithm ID is used as the type identifier because the structures contain parameters that are specific to the types of operations that can be performed on or with the object. For example, an RSA type would contain an RSA key pair that could be used for operations defined for RSA. An AES type would be used for symmetric encryption or decryption.
nameAlg	This is a second algorithm ID that identifies the hash algorithm used for computing the Name of the object.
objectAttributes	This contains the set of attributes of the object. These attributes are in five classes: 1) usage (*sign*, *encrypt*, *restricted*); 2) authorization (*userWithAuth, adminWithPolicy, noDA*); 3) duplication (*fixedParent, fixedTPM, encryptedDuplication*); 4) creation (*sensitiveDataOrigin*); and 5) persistence (*stClear*).
authPolicy	This will contain the authorization policy for the object if one is defined. *nameAlg* is used as the *authPolicy* hash algorithm, NOTE An object that is intended to be duplicated must have an *authPolicy* enabling the duplication.
[type]parameters	The parameters of an object are dependent on the object *type*. For symmetric key object, the parameters would indicate the size of the key and the default encryption mode. For an asymmetric object (RSA or ECC), the parameters would indicate the key size, signing scheme, and symmetric encryption methods associated with the key.
[type]unique	The unique value of an object is also dependent on the object *type*. For an asymmetric object, this will be the public key. For a symmetric object, this will be a value computed by hashing values in the sensitive area.

26.3 Sensitive Area

The sensitive area is related to the public area and contains the data that are required to be encrypted when not in a Shielded Location on the TPM. It contains the authorization value and the item-specific

Copyright © TCG 2006-2020

information such as the private or secret portion of a key. If an object is a Storage Key, it contains the symmetric key that is used to encrypt its child object.

The structure of the sensitive area is shown in Table 27.

Table 27 — Sensitive Area Parameters

Parameter	Description
sensitiveType	This identifies the type of the object for this sensitive area. This value and the type parameter of the public area are the same.
authValue	This is the authorization value for the object. It is an octet array of zero or more octets. The authorization value for an object may not have more octets than the digest produced by the object's *nameAlg*.
seedValue	This value is required for Storage Keys and is the seed used to generate the protection values for the child objects of the Key. This is optional for asymmetric keys that are not Storage Keys and is not used if present. For all other object types, this is an obfuscation value. It is hashed with the *sensitive* field to produce the *unique* value in the public area. Including this value in the computation obfuscates *unique* so that the *sensitive* value cannot be determined from the *unique* field.
[sensitiveType]sensitive	The contents of this parameter are dependent on *sensitiveType.* For an asymmetric key, this will contain the private key. For a symmetric key, this will be the key. For an HMAC key this is the HMAC key value. For a data object, this will be the sensitive data.

Each sensitive area created by the TPM contains some TPM-created data that makes each sensitive area statistically unique. This will be either an asymmetric key or a large random number. The unique values in the sensitive area are cryptographically linked to values in the public area in a way that makes each public area statistically unique. The fact that a sensitive area is statistically unique and cryptographically linked to a public area ensures that a TPM can detect any attempt to substitute the sensitive area associated with a public area.

NOTE Such a substitution would allow subversion of secrets-based policy authorization. If an attacker could use an arbitrary sensitive area with a public area with a known Name, the attacker could perform TPM2_PolicySecret() and cause the *policyDigest* to be updated with the chosen Name even though the attacker does not know the authorization value of the correct sensitive area. Cryptographic linking of the sensitive area to the public area ensures that this type of attack is not practical.

26.4 Private Area

When a sensitive area is not in a Shielded Location on a TPM, it is integrity-protected and symmetrically encrypted. There is more than one format for a protected sensitive area but the loadable (TPM2_Load()) form of the protected sensitive area is called a "private" area.

NOTE 1 Another format is a saved context.

The process of converting a sensitive area to a private area requires that the sensitive area be marshaled to its canonical form. This marshaled structure is then encrypted using a key derived from the Storage Parent's symmetric seed (*seedValue*). An HMAC is performed over the data with the Name of the associated sensitive area include in the HMAC. The combination of the HMAC and the encrypted sensitive area is a key's private area.

NOTE 2 Similar protections are used when an object is context saved or duplicated.

 Copyright © TCG 2006-2020

26.5 Qualified Name

The Qualified Name (QN) of an object is the digest of all of the Names of all of the ancestor keys back to the handle of the Primary Seed at the root of the hierarchy. The QN of an object includes the Name of the object. The QN uses the Name hash of the current object to compute the QN for the object.

EXAMPLE 1 Assuming that key A is the Storage Parent of object B, then the Qualified Name of B (QN_B) is:

$$QN_B \coloneqq \mathbf{H}_B\ (QN_A \mid\mid NAME_B)$$

The QN is not a digest of all of the entities loaded into the TPM. It is a digest of all of the entities in a chain.

EXAMPLE 2 Assume two entities with public areas of A and B and different Name hash algorithms (H_A and H_B). Also assume that they share the same parent P with a QN of QN_P. The QN for A is $QN_A \coloneqq H_A(QN_P \mid\mid H_A(A))$ and the QN for B is $QN_B \coloneqq H_B(QN_P \mid\mid H_B(B))$.

The primary purpose of the Qualified Name is to supplement the environmental information relating to object creation and object use. The environment of an object includes its hierarchy. The hierarchy starts at a Primary Seed and includes all ancestor keys for the object. The Qualified Name of an object is included in its creation data. The Qualified Name permits validation that a list of ancestor Names is correct. It is then possible to determine if, for example, all ancestor keys use sufficient cryptographic strength. The Qualified Name of an object is included in its certification to indicate that the key is being used in a different environment (ancestry) than the one in which it was created.

Both the Name and Qualified Name for a Primary Seed are the handle of the Primary Seed. If the parent handle is TPM_RH_NULL, Name and QN are also TPM_RH_NULL. This makes the QN of a Primary Object or Temporary Object equal to:

$$QN \coloneqq \mathbf{H}_{nameAlg}\ (A\ hierarchy\ handle \mid\mid Primary\ Object\ Name) \tag{48}$$

NOTE The creation data for an object includes both the Name and QN of the Storage Parent of that object.

26.6 Sensitive Area Encryption

When a sensitive area is in a loadable format (a private area), the symmetric encryption key is derived from the secret seed (*seedValue*) of the parent.

When a sensitive area has been encrypted for duplication, the sensitive area is symmetrically encrypted with a key that is protected using asymmetric methods associated with the new parent. Before a duplicated object may be loaded, it must be “imported” (TPM2_Import()) and encrypted using the symmetric key derived from the secret seed of the new parent.

NOTE Clause 30.3 describes the protections that are applied to a sensitive area when it is part of a saved context.

All symmetric encryption of the sensitive area uses Cipher Feedback (CFB) mode.

The method of generating the encryption key and IV for the encryption is described in clause 22.

26.7 Sensitive Area Integrity

When an object is not in a Shielded Location, it is susceptible to modification through means other than through a Protected Capability. An HMAC-based integrity scheme allows these modifications to be detected. The integrity HMAC includes the sensitive data and some representation of the public area. Inclusion of the public area preserves the binding between the two elements of the object.

 Copyright © TCG 2006-2020

The HMAC key is generated from the same seed that is used for generating the symmetric encryption key and IV. The HMAC of the protected structure is required to be checked before the sensitive area is decrypted.

 Copyright © TCG 2006-2020

27 Object Creation

27.1 Introduction

TPM2_Create(), TPM2_CreatePrimary() and TPM2_CreateLoaded() are used to create the objects (keys and data) that are part of a TPM's Storage hierarchy. TPM2_CreatePrimary() is used to create Primary Objects that are derived from a Primary Seed. TPM2_Create() is used to create Ordinary Objects that are generated with values from the TPM RNG. TPM2_CreateLoaded() can be used to create a Primary or Ordinary Object.

NOTE 1 TPM2_CreateLoaded() may also be used for Derived Objects. This is covered in more detail in clause 28.

Table 28 — Creation Commands

Creation command	**TPM2_CreatePrimary()**	**TPM2_Create()**	**TPM2_CreateLoaded()**		
Parent Handle Type	Primary Seed	Storage Parent	Primary Seed	Storage Parent	Derivation Parent
Created Object Type	Primary	Ordinary	Primary	Ordinary	Derived
Public Area Returned	yes	yes	yes	yes	yes
Sensitive Area Returned	no	yes	no	yes	no
***creationData* Returned**	yes	yes	no	no	no

Table 28 compares and contrasts the creation of objects by TPM2_CreatePrimary(), TPM2_Create(), and TPM2_CreateLoaded(). In particular, when creating keys:

- TPM2_CreatePrimary() – creates and loads Primary Objects for immediate use and provides creationData.
- TPM2_Create() – creates Ordinary Objects for later use (via TPM2_Load()). TPM2_Create() returns a BLOB containing the sensitive area of an Ordinary Object and provides creationData.
- TPM2_CreateLoaded()– depending on the type of the parent, generates and loads a Primary Object, an Ordinary Object; or Derived Object.

Authorization to use the Parent is required in order to generate a child. Authorization to use a Primary Seed is required in order to create a Primary Object.

All of the objects created by these commands are similar in most respects. For TPM2_Create() and TPM2_CreatePrimary(), the parameters required to create an object are the same for both commands. They are:

- a public area template,
- the sensitive values,
- optional user-provided identification data, and
- the optional creation PCR selection.

For TPM2_CreateLoaded(), the only parameters are the public area template and the sensitive values.

NOTE 2 The user-data and PCR parameters are not used for TPM2_CreateLoaded() as it does not return the *creationData* used for creation certification. For objects where the creation certification is necessary, the TPM2_Create() or TPM2_CreatePrimary() functions are available.

 Copyright © TCG 2006-2020

Any type of object that can be created with TPM2_Create() can be created with TPM2_CreatePrimary() or TPM2_CreateLoaded().

NOTE 3 TPM2_CreateLoaded() can be used for creation of asymmetric keys but it may not be used for derivation of certain types of asymmetric keys. This limitation is because of the variability in algorithms for some asymmetric key types (such as RSA).

The sensitive area of an Object created from a seed does not leave the TPM except in a saved context or by duplication. If a Primary Object is not context saved (and not persistent), it will need to be recreated after the next TPM2_Startup(). Even if context saved, if a Primary Object is not made persistent in the TPM (TPM2_EvictControl()), it will need to be recreated after each TPM Reset.

27.2 Public Area Template

27.2.1 Introduction

A public area template describes the desired attributes of the object to be created. The TPM uses this template to guide the creation of the new object.

The format of the template has to match the desired format of the object to be created, in all details. The item-specific information (the *unique* field) will be replaced by the TPM in the creation process, but all other fields in the created object will be identical to those in the template.

In general, the fields in the public area are checked as if the object were being loaded under the Storage Parent indicated in the creation command.

27.2.2 type

This parameter indicates the basic type of the object and determines the format of the *parameters* and *unique* fields. The type may indicate a symmetric key, an asymmetric key, or a data value.

The allowed values for *type* are: TPM_ALG_SYMCIPHER, TPM_ALG_KEYEDHASH, TPM_ALG_RSA, or TPM_ALG_ECC.

NOTE The list of types may change. If an algorithm ID is allowed for use as a public area type, it is denoted by an "O" in the "Type" column of the TPM_ALG_ID constants table published by the TCG.

27.2.3 nameAlg

The *nameAlg* parameter in the template is set according to the object type. If the object is a restricted-decryption key, then the object is required to have the same *nameAlg* as the Storage Parent. For all other cases, the *nameAlg* may be any supported hash algorithm.

In the case of TPM2_LoadExternal(), *nameAlg* is allowed to be TPM_ALG_NULL. When this value is selected, the TPM does not validate the cryptographic linkage between the public and sensitive portions of the object. Since the *nameAlg* is TPM_ALG_NULL, the object has no Name.

NOTE Certification of the key with no Name has no meaning as the certification will have no Name for the certified object.

27.2.4 objectAttributes

These flags must be set according to the rules appropriate for loading the object. The required settings are found in TPM 2.0 Part 2, in the definition of TPMA_OBJECT.

 Copyright © TCG 2006-2020

27.2.5 authPolicy

If use of an object is to be gated by a policy (including PCR), the template will contain the policy hash. Otherwise, this entry will be set to the Empty Policy.

27.2.6 parameters

This field contains parameters that describe the details of the object indicated in *type*.

For a Storage Key that has *fixedParent* SET in its *objectAttributes*, these parameters will be identical to the parameters of the Storage Parent. For other objects, these parameters may vary according to the *type* and application.

27.2.7 unique

The *unique* field of the template is the only field in the public area that is replaced by the TPM during the object creation process. The caller may place any value in this field as long as the structure of the value is consistent with the *type* field. That is, this field should be structured in the same way as the data that will be placed in this field by the TPM. The caller may also set the size of this field to zero and the TPM will replace it with a correctly sized structure.

27.3 Sensitive Values

27.3.1 Overview

The sensitive values that are provided when the object is created allow initial setting of the *authValue* for the object and may provide some other object-sensitive value. The sensitive value may be an encryption key or sealed data.

The sensitive values provided to the TPM in TPM2_Create() and TPM2_CreatePrimary() (the inSensitive parameter) may optionally be encrypted using standard session-based encryption techniques. Since session-based encryption allows use of a different session for authorization and encryption, the session used for encrypting the authorization and other sensitive data does not have to be the same as the authorization session for the Storage Parent of the newly created object. This ensures that the entity that controls the Storage Parent does not automatically gain access to the secret values of a child.

27.3.2 userAuth

The *userAuth* value is the initial *authValue* for the created object. This value may be no larger than the digest produced by the *nameAlg* of the object.

NOTE This limitation ensures that any valid *authValue* will be usable on any TPM that can load the key. If this limitation were not imposed, then some TPM might not be able to load a duplicated object because the *authValue* was too large for the implementation.

27.3.3 data

This contains information that the caller wants to be incorporated in the sensitive part of the created object. This may be either a symmetric key or user data. If *data* is an Empty Buffer, then the *sensitiveDataOrigin* attribute of the template is required to be SET. If data is not empty, then *sensitiveDataOrigin* is required to be CLEAR.

 Copyright © TCG 2006-2020

If the object type is TPM_ALG_KEYEDHASH and both *sign* and *encrypt* are CLEAR, then the created object is a Sealed Data Object and the TPM will return an error (TPM_RC_SIZE) if *data* is an Empty Buffer.

If the created object is an asymmetric key and not a primary key, then *data* is required to be an Empty Buffer and *sensitiveDataOrigin* in the template is required to be SET. For a primary key, *data* permits personalization of the key with private data, data that can be provided as an encrypted parameter.

NOTE If the caller were allowed to specify the private key, then for some types of asymmetric algorithms (such as, ECC) the actions of the TPM would not determine the Name of the object. Since the TPM has no effect on the creation of such an object, the preferred means of having such a key become part of a hierarchy is to import it with TPM2_Import().

27.4 Creation PCR

The PCR selection that is present in TPM2_Create() or TPM2_CreatePrimary() parameters is used to select the PCR values that will best represent the environment in which the object was created. The selection and the PCR are hashed according to the creation data algorithm and included in the creation data (a TPM2B_CREATION_DATA) that is returned in the command response.

NOTE When an Object is created, the TPM produces a ticket that it (the TPM) can use to verify that it created the Object. This allows the TPM to certify that it created the Object (TPM2_CertifyCreation()).

27.5 Public Area Creation

27.5.1 Introduction

This clause describes how the TPM uses the parameters of TPM2_Create() and TPM2_CreatePrimary() to set the values in the public area of the created object.

This clause does not describe the error conditions if the parameters are bad. That information is provided in the description of TPM2_Create() and TPM2_CreatePrimary() in TPM 2.0 Part 3.

27.5.2 type, nameAlg, objectAttributes, authPolicy, and parameters

The TPM will validate that these parameters are consistent in the template and then copy them from template into the created structure without modification.

27.5.3 unique

27.5.3.1 Introduction

This parameter will contain a *type*-specific structure. It is used to ensure that each object has a statistically unique identity. The methods used to create *unique* ensure that it is cryptographically bound to the contents of the sensitive area. Creation of *unique* from the sensitive data uses non-invertible processes (such as, a hash) so that the *unique* value does not compromise the confidentiality of the sensitive area.

The computation of *unique* uses one or more values in the sensitive area of the object. At least one of the sensitive area values will be provided by the TPM to ensure that *unique* is, in fact, unique. For asymmetric keys, uniqueness is provided by the public key and the public key is mathematically linked to the private key in the sensitive area.

 Copyright © TCG 2006-2020

For symmetric objects (symmetric keys, HMAC keys, and data blobs), the key (or data) is hashed with a TPM-generated obfuscation value and the resulting digest is used as the *unique* value.

There are two reasons for generating the *unique* parameter for symmetric objects in this way. The first is that it protects the contents of the user-provided data. If the secret data has low entropy, then making the *unique* parameter a simple digest of that data would allow an offline attack to determine what the secret data might be. The large, random, obfuscation value generated by the TPM is not known to an attacker, which mitigates this threat.

The second reason for this method is that it prevents an attacker from stealing an object's identity. If the identity were not based on the contents of the sensitive area, then an attacker could create a sensitive structure and associate it with the public area of any symmetric object. Having the sensitive area contain information that can cryptographically link the sensitive area to the public area prevents this kind of substitution.

The methods for producing *unique* for each of the object types are described in the remainder of 27.5.3.

27.5.3.2 TPM_ALG_KEYEDHASH

This type is used for an HMAC key or data block. The computation for *unique* for a KeyedHash object is:

$$unique \coloneqq \mathbf{H}_{nameAlg}\left(obfuscate \mid\mid key\right) \tag{49}$$

where

$\mathbf{H}_{nameAlg}$	hash using *nameAlg* from the object template
$obfuscate$	the contents of *seedValue.buffer* in the object's sensitive area
key	the contents of *sensitive.bits.buffer* in the object's sensitive area; this will be either an HMAC key, a data blob, or a symmetric key.

27.5.3.3 TPM_ALG_SYMCIPHER

This type is used for a symmetric block cipher key. The *unique* value is computed as shown in (49).

27.5.3.4 TPM_ALG_RSA

For an RSA key, *unique* is the public modulus of the key. It is computed as described in B.8.

27.5.3.5 TPM_ALG_ECC

For an ECC key, *unique* is the public point computed as described in C.5.

27.6 Creation Entropy

27.6.1 Introduction

The reference code uses common algorithms for generating keys of a specific type. That is, there is one algorithm for generating RSA keys, one for ECC keys, one for HMAC keys and one for symmetric keys.

NOTE RSA and ECC are "if implemented."

 Copyright © TCG 2006-2020

When calling these functions, the caller is allowed to indicate where the function should get entropy for use in the algorithm. This allows these functions to be used for Primary, Derived, and Ordinary Objects simply by changing the source of “entropy.”

Table 29 — Deriving Object Entropy

Object Type	Source of Object Entropy	Described in Clause
Primary	DRBG initialized using a hierarchy seed and the hash of the input template	27.6.3
Ordinary	TPM’s default DRBG	27.6.2
Derived	KDF	28.4

Table 29 compares and contrasts the methods used to create the cryptographic values of primary, ordinary and derived keys.

- A Primary Object is intended to be created multiple times, in the absence of any other key, with the minimum amount of persistent storage. As a result, the cryptographic values of primary keys are created by instantiating a DRBG.
- An Ordinary Object is intended to be created exactly once and persistently stored. As a result, the cryptographic values of ordinary objects are created by the DRBG that is used by default when a TPM requires random data. This DRBG is seeded with entropy when the TPM was created and topped-up with additional entropy added at intervals.
- A derived key is intended to be derived multiple times from a parent key, and not persistently stored. As a result, the cryptographic values of derived keys are created by applying a KDF and hash algorithm specified in the Derivation Parent to the Derivation Parent’s symmetric key, using label and context values provided by the caller.

27.6.2 Entropy for Ordinary Objects

For an Ordinary Object, the caller would pass a NULL pointer. When the key generation function needs a random number, it would pass that NULL pointer to the random number generator. Because the pointer is NULL, the random number generator will use the default random number generator of the TPM which produces numbers that are as random as the TPM is able to produce.

27.6.3 Entropy for Primary Objects

For a Primary Object, the caller would instantiate a deterministic random number generator (DRBG) and seed the DRBG with a primary seed, a template hash, and a use string. The key generation function would pass this pointer to the random number generator which would use this state instead of the TPM’s default state. This produces a sequence of bits that have as much entropy as the primary seed and which have a property that is required for generating a Primary Object – the DRBG state can be reinstantiated each time the same Primary Object is created.

Choice of the entropy generation for Primary Objects is a vendor option.

NOTE The reference implementation uses a DRBG based on SP800-90A in order to minimize compliance issues.

27.7 Sensitive Area Creation

27.7.1 Introduction

This clause indicates how the TPM creates the sensitive portion of an object (a TPMT_SENSITIVE).

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

The process for computing the contents of a sensitive area is determined by the type of the object, indicated in the *type* field of *template*.

Some of the sensitive area fields may contain data that is provided by the caller. Some of the fields are always provided by the TPM. When a TPM-provided field is in a Primary Object, the TPM-provided data is always derived, in some way, from the associated Primary Seed such that the same Primary Object can be reproduced as long as the associated Primary Seed remains unchanged. For Ordinary Objects, an implementation may either get the TPM-provided data from the RNG or compute the fields of the object as if it were a Primary Object, but with a random number used in place of a Primary Seed.

The performance difference between the two methods of producing asymmetric objects is negligible as the majority of the work is in validating the choices rather than in generating them. For symmetric objects, the difference might be worth having different methods for Primary and Ordinary Objects but there is an added cost in development and testing that could offset the benefit of any slight performance advantage.

For Ordinary Objects, the method used for generating *sensitive* should be used for generating *seedValue*. That is, if *sensitive* is generated by taking values from the RNG, then *seedValue* should be generated by taking values from the RNG. If *sensitive* is generated by creating a random seed and using the methods used for Primary Keys, then that same seed should be used for generating *seedValue*.

27.7.2 type

The *type* parameter of the object's sensitive area is a copy of the type parameter from the object's public-area template.

27.7.3 authValue

The *authValue* of the object is copied from the *userAuth* field of the *inSensitive* parameter of commands such as TPM2_Create(), TPM2_CreateLoaded, or TPM2_CreatePrimary(), or from *newAuth* in commands such as TPM2_ObjectChangeAuth.

When the TPM returns a TPM2B_PRIVATE structure, the TPM pads the TPM2B_AUTH to its maximum size.

NOTE This prevents the TPM from leaking the size of the authorization value in cases where trailing zeros are stripped.

27.7.4 *seedValue*

For a symmetric object, *seedValue* field is used as an *obfuscation* value. It is also used to hold the symmetric seed value for Storage Keys.

For an asymmetric key that is not a Storage Key, *seedValue* is not needed and the TPM will ignore the value if it is present.

For a Storage Key, *seedValue* is used as a seed for generating the integrity and confidentiality values for protecting child objects of the key.

For all object types, when the TPM generates *seedValue*, it is the size of the digest produced by the *nameAlg* of the object.

NOTE 1 Presuming that the protection algorithms of a Storage Key are reasonably balanced (a requirement), then this size of seed will provide adequate entropy required for protection of the child Object.

For an imported symmetric object, *seedvalue* is required to be the size of the digest produced by the *nameAlg* of the object.

For an imported Storage Key, *seedvalue* is required to be at least to be at least half the size of the digest produced by the nameAlg.

NOTE 2 This requirement is for backward compatibility.

For Imported asymmetric non-Storage Keys, *seedValue* is not required.

NOTE 3 The rationale for these requirements derive from the use of *seedValue*. When *seedValue* is used in a hash, it must be the full size. When used in an HMAC, it can be half the size.

seedValue is generated using the “entropy” source used for the object type (see 27.6).

When creating a Primary Object in the Endorsement Hierarchy, it is required that the entropy source be updated to reflect the current SPS. This allows the *sensitiveValue* to remain the same after a change of the SPS but prevents any previously-generated Child Objects in the Endorsement Hierarchy from being loaded after the SPS changes.

NOTE 3 In the reference implementation, this is accomplished by reseeding the DRBG state with the proof value of the storage hierarchy.

27.7.5 sensitive

27.7.5.1 Symmetric Objects

Symmetric objects have a *type* of TPM_ALG_SYMCIPHER or TPM_ALG_KEYEDHASH. For a symmetric object, the sensitive object data may be provided by the caller or generated by the TPM.

If *sensitiveDataOrigin* attribute in the object template is CLEAR, then the sensitive data is provided by the caller. If provided by the caller, the sensitive data will be in the *data* field of the *inSensitive* parameter of TPM2_Create() or TPM2_CreatePrimary(). For TPM2_CreateLoaded(), if the Parent is a Derivation Parent, then *sensitiveDataOrigin* is required to be CLEAR in the template.

If *sensitiveDataOrigin* is SET, it indicates that the TPM is the source of the sensitive data and the data field of the *inSensitive* parameter is required to be an Empty Buffer.

A user provided symmetric key is required to be the size indicated by *parameters.symDetail.keyBits.sym* in the template. It is the number of octets required to hold the number of bits indicated.

NOTE 1 If the key has fewer significant digits than necessary, pad octets of zero are required. The pad octets are added to the high-order end of the key.

A user provided HMAC key is not allowed to be larger than the smaller of the block size of the hash algorithm or 128 octets. Limiting the size to 128 octets is for compatibility of structures between TPM.

NOTE 2 The HMAC algorithm requires that keys larger than the hash block size be hashed before use. This may result in fewer bits of entropy in the HMAC key than expected by the caller. The TPM will not allow the caller to specify an overly large value for the HMAC key. If the caller desires to use a larger value, they should perform the digest externally and pass the resulting digest to the TPM for use as the HMAC key.

If not provided by the caller, *sensitive* is generated by the TPM. For a TPM_ALG_KEYEDHASH object, the size is the digest size of the nameAlg of the object. For a TPM_ALG_SYMCIPHER object, the size is equal to (*parameters.symDetail.keyBits.sym* + 7) / 8.

 Copyright © TCG 2006-2020

27.7.5.2 Asymmetric Objects

The *sensitive* field in an asymmetric key object is the private key. The key is generated in a way that is specific to the algorithm and is described in an algorithm-specific annex of this TPM 2.0 Part 1.

EXAMPLE RSA key generation is described in B.8 and ECC key generation is described in C.5.

27.8 Creation Data and Ticket

When it creates an object, the TPM also creates a data structure that describes the environment in which the object was created. This data includes:

- a digest of selected PCR at the time of object creation and a bit-map indicating the PCR that were included in the list. The PCR selection is those PCR indicated in the call to TPM2_Create() and TPM2_CreatePrimary().
- the locality at which the object was created
- the *nameAlg* of the Storage Parent. If the parent is a Primary Seed, then the algorithm will be TPM _ALG_NULL.
- the Name of the Storage Parent. If the parent is a Primary Seed, then the Name will be the handle of the seed.
- the Qualified Name of the Storage Parent. If the parent is a Primary Seed, then the Qualified Name will be the handle of the seed.
- some additional data provided by the caller that is to be associated with the new object

In addition to these values, the TPM will create a ticket that will allow the TPM to validate that the creation data was generated by the TPM.

The creation data will act as a form of certification of the object that is most useful when *fixedTPM* is CLEAR in the created object. Without this information, it would not be possible to determine how the object came to be in the hierarchy where it is found. When the object is moved, it would be up to the duplication authority to provide some certification of the duplication process. If there is no creation data indicating that the object was created in the place where it was found, and there is no certificate from the duplication authority for the object, then it may be difficult to establish the trustworthiness of the object.

NOTE In this case, the trustworthiness of the object refers to determining that the sensitive area of the object has only ever been accessible by trusted entities such as other TPMs.

27.9 Creation Resources

When a Primary Object is created, it is also loaded in a TPM object slot and the handle is returned. If no free object slot is available, the TPM will return TPM_RC_OBJECT_MEMORY.

When creating an ordinary object, the TPM may use an object slot as scratch memory in which it builds the object. If the implementation does use this scheme and no object slot is available, then the TPM will return TPM_RC_OBJECT_MEMORY.

28 Object Derivation

28.1 Introduction

This section describes the differences between Object creation and Object derivation. If no difference is stated, then there is none.

The TPM2_CreateLoaded() command is used for derivation. This command can be used to create or derive any type of object with the type of Object determined by the type of the entity referenced by the *parentHandle* parameter. If *parentHandle* references a Primary Seed, then a Primary Object is created; if *parentHandle* references a Storage Parent, then an Ordinary Object is created; and if *parentHandle* references a Derivation Parent, then a Derived Object is generated.

NOTE For a given template (*inPublic*), the same Primary Object is created by both TPM2_CreatePrimary() and TPM2_CreateLoaded().

28.2 Derivation Parameters

For object derivation the TPM uses the *sensitive* value in a Derivation Parent as a key in a key derivation function (KDF). The KDF that is to be used in Object derivation is a property of the Derivation Parent and may include the hash algorithm to use in the derivation process.

NOTE **KDFa** (TPM_ALG_KDF1_SP800_108) is the only KDF that is currently supported by the reference code,

Most KDFs require additional parameters in order to have different types of keys derived for different applications. The TPM allows two additional parameters (*label* and *context*) to be provided in TPM2_CreateLoaded(). These additional parameters can be provided in two ways: in the *unique* field of the *inPublic* value, or in the *data* field of the *inSensitive* parameter. If provided in the *unique* field, the corresponding value in the *inSensitive.data* field is ignored.

28.3 Public Area Template

For TPM2_CreateLoaded(), a TPM2B_TEMPLATE is used for the *inPublic* parameter instead of a TPM2B_PUBLIC. The difference in parameters is to allow overloading of the *unique* field in the *inPublic* parameter. For a TPM2B_PUBLIC, the *unique* field is unmarshaled based on the *type* of *inPublic.* For a TPM2B_TEMPLATE, the *inPublic* is unmarshaled as a byte array and passed to the TPM2_CreateLoaded() action code where it is unmarshaled based on the type of parent and *type* of *inPublic.*

When using TPM2_CreateLoaded() to create a Primary or Ordinary Object, the caller should use the same format for the unique field that would be used when creating the Object with TPM2_CreatePrimary() or TPM2_Create(). The derivation-specific format is required when *parentHandle* references a Derivation Parent.

For object creation, *sensitiveDataOrigin* indicates to the TPM whether the caller is providing the sensitive data or if the TPM is to generate it. For Object Derivation, the caller provides values that influence the derivation process, but the caller does not explicitly set the sensitive value. For this reason, *sensitiveDataOrigin* is required to be CLEAR in the template for a Derived Object.

 Copyright © TCG 2006-2020

28.4 Entropy for Derived Objects

28.4.1 Conceptual Description

The ‘entropy’ for a Derived Object is provided by a protected value in the sensitive area of the derivation parent (the sensitive value). That entropy, along with caller-provided values, is used in a KDF to spread the entropy across values in the derived object. Those derived values are the *sensitive* and *seedValues*. The remainder of the Derived Object is provided by the template or computed from the two derived values.

KDFa is used for the derivation. The parameters for the derivation are:

$$\mathbf{KDFa}\ (hashAlg, sensitive, [label,]\ [context,]\ 0, 8192) \qquad (1)$$

where:

hashAlg	the *nameAlg* of the derivation parent
sensitive	the *sensitive* value in the sensitive area of the derivation parent
label	an optional string provided by the caller
context	an optional string provided by the caller

KDFa has a counter and a bits parameter that are set, as shown above, to 0 and 8192 respectively.

NOTE In order to be compliant with SP800-108, the KDFa function will increment counter to 1 before using it in the generation of the first HMAC block.

This call will cause the KDF to generate 1024 bytes of data, with the results of the first digest being the most significant bytes.

During the derivation process, the data is removed from the 1024-byte buffer as needed for each use. The data is used from most significant byte to least significant byte with no bytes skipped. For most key generations, a deterministic number of bytes will be removed for each of the derived fields (*sensitive* and *seedValue*).

Example 1 For a 128-bit AES key in a SYMCIPHER object having SHA-256 as its *nameAlg*, the most significant 16 bytes of the KDF data are used for the AES key and the next-most-significant 32 bytes are used for the *seedValue*.

Example 2 For ECC, the TPM uses the method of FIPS 186-4 B.4.1 Key Pair Generation Using Extra Random Bits. For a 256-bit ECC key, the most-significant 40 bytes are used to generate the private key and, if the *nameAlg* of the derived object is SHA-256, the next-most-significant 32 bytes will be used for the *seedValue*.

In some cases, the number of bytes used for the *sensitive* value is indeterminate. This is because some of the generated values are unsuitable for the application and may need to be discarded. In such cases, bytes are taken from the 1024-byte buffer until suitable values for *sensitive* have been found and the next most significant bytes are used for *seedValue*.

Example 3 Not all 64-bit values are suitable for use as DES keys. When the derivation process produces one of these values, the key will be discarded, and the next most significant bytes are taken from the 1024-byte KDF buffer.

When suitable values for both *sensitive* and *seedValue* have been extracted from the 1024-byte KDF buffer, the remaining bytes are discarded.

 Copyright © TCG 2006-2020

28.4.2 Implementation Alternatives

There are various ways to produce an implementation that is compatible with the conceptual description above without actually having to generate 1024 bytes of data. Some examples are given here:

- An implementation may compute the number of bytes that will be needed to produce the *sensitive* and *seedValue* and the KDF would only need to generate that number of bytes. The bits parameter in the call to generate the data would still need to be 8192. In order to facilitate this type of implementation, the *CryptKDFa*() function in the reference code has a blocks parameter that limits the number of returned blocks, regardless of the size of the *sizeInBits* parameter.
- An implementation may generate blocks on a demand basis. This is fairly complex but allows the derivation process to be used as if it were any other RBG. To implement this process, the calling parameters of the KDF are saved in a structure so that they are available for multiple calls. This structure is passed to the functions that use a random number generator. When random bits are needed, the generator checks the type of the random number generator context and, if it contains KDF parameters, they are used in a call to the KDF. After each call, the counter value is incremented so that the net effect of generating one block at a time is the same as generating all of them at the same time. The additional complexity of this implementation is that it is required that all of the bytes from the KDF be used in order, with none skipped. In order to deal with a call that does not use a full block, a buffer is added to the KDF structure in which residual bytes are saved. When a call is made to fetch bytes from the KDF, the residual buffer is checked first and any bytes in that buffer are returned before the KDF is called to produce additional bytes. If the KDF produces a block and not all bytes are returned, the residual bytes are placed in the buffer. This provides continuity of bytes as required by 28.4.1.

28.5 Derivation Process

The derivation process is required to be the same for all TPMs. That is, with the same inputs, all TPMs will generate the same Derived Objects.

When generating a Derived Object, the TPM will create the entropy structure for a KDF and pass a pointer to the structure to the function that creates Objects. The algorithm for generating an Object is as described in clause 27.7.

NOTE The method of generating RSA keys is highly variable and is normally chosen according to the constraints of the application. In some cases, compliance is the overriding factor and in others, performance may be the determining factor. Since no single algorithm seems to be optimum for all the constraints and it would not be acceptable to require that TPMs implement one RSA key generation for compliance and one for interoperability, the TCG has chosen not to support derivation for RSA keys.

29 Object Loading

29.1 Introduction

An object is either a key or data that can be loaded into the TPM for use. An object must be loaded before the TPM can use or modify the object. Loading may require that the USER role authorization for the Storage Parent be provided

29.2 Load of an Ordinary Object

It is possible to load just the public portion of an object into the TPM (TPM2_LoadExternal()) or to load both the public and private portions (TPM2_Load()). If the sensitive area is to be manipulated or used, then both portions are required to be loaded.

When loading an object, multiple consistency checks are performed. Among these checks:

a) Is the HMAC of the encrypted private area correct – this ensures that the sensitive area was not modified, that the sensitive area and the provided public area are matched, and that the object is a descendant of the Storage Parent.

b) Is the unique parameter of the public area cryptographically bound to the sensitive data – this is required to prevent improper association of a public area with a sensitive area. If this check were not done, an attacker could use a public area that had a Name that is the same as a different object and associate a different sensitive area with the public area. If the object were used in TPM2_PolicySecret(), the attacker could get the TPM to create a *policyDigest* with any desired hash value.

   EXAMPLE A legitimate policy uses signature validation of a key with Name1. An attacker could create an object with Name1 (copy the data from the legitimate key) and then create a sensitive area that had an *authValue* known to the attacker, instead of using TPM2_PolicySigned() to create the policy.

c) Are the attributes consistent – these values need to be checked even if the integrity check indicates that the values were not modified. This is because the object may have been created by software using inconsistent values. The integrity may be good, but the values may be wrong.

   1) If *fixedTPM* is SET, *fixedTPM* must also be SET in the Storage Parent.

      NOTE If *fixedTPM* is properly SET, then the other checks need not be made because the object is verified to have been created on the TPM that loaded the object, so the other attributes are known to be correct.

   2) If *fixedParent* is CLEAR, then *fixedTPM* must also be CLEAR.

   3) If *restricted* is SET, only one of *sign* or *decrypt* may be SET.

29.3 Public-only Load

There are several cases, such as duplication or signature verification, when only the public portion of an asymmetric key can be loaded. The public-only load of an object requires that the caller associate the object with one of the hierarchies. This association is needed when the key is used for signature verification so that the TPM can determine which proof value to use in the ticket.

A public-only load occurs when the *inPrivate* parameter to TPM2_LoadExternal() has a size of zero.

29.4 External Object Load

External Objects allow the cryptographic processes of the TPM to be used on keys that are not part of a TPM hierarchy. The public portion of an asymmetric key may be loaded so that the TPM can be used to validate a signature. A symmetric key may be loaded so that the symmetric engines of the TPM may be used to encrypt or decrypt data.

TPM2_LoadExternal() is used to load an External Object. When only the public portion is loaded, the attributes of the object are arbitrary, but the structures are required to be consistent with the type. That is, if an RSA signing key is loaded, the signing scheme must be a valid scheme for an RSA key.

When the sensitive portion of the object is loaded (such as, a symmetric key), the sensitive area is not encrypted by a Storage Parent but may be encrypted using parameter encryption. The *fixedParent* and *fixedTPM* attributes are required to be CLEAR when both parts are loaded. This check allows the object to be used in any command that is valid for the type including certification.

NOTE If an entity has access to both the public and sensitive portions of a key, then the entity could import the key and then certify it.

An external object can be associated with a hierarchy when it is loaded. This allows creation of tickets that are specific to a hierarchy in commands such as TPM2_VerifySignature().

If the hierarchy with which an External object is associated is disabled, the object will be flushed. If the associated hierarchy is disabled when TPM2_LoadExternal() is called, the object will not load.

30 Context Management

30.1 Introduction

To allow the TPM to be shared among many applications, the TPM supports context management. The objects, sequence objects, and sessions used by an application may be loaded into the TPM when needed and saved when a different application is using the TPM. The TPM Resource Manager (TRM) is responsible for swapping the contexts so that the necessary resources are present in the TPM when needed.

There are two types of contexts: those associated with Transient Objects, and those associated with authorization sessions.

The four commands used to manage the contexts are

1) **TPM2_ContextSave()** – the TPM integrity protects, encrypts, and returns the context associated with a handle,
2) **TPM2_ContextLoad()** – allows a previously saved context to be loaded to TPM RAM and have a handle assigned,
3) **TPM2_FlushContext()** – the context information associated with the specified handle is erased from TPM RAM, and
4) **TPM2_EvictControl()** – allows the owner or the platform firmware to designate objects that are to remain TPM-resident over TPM2_Startup() events. This command will return a new handle.

A saved context is cryptographically bound to a specific TPM so that it may not be loaded on a different TPM. This binding is provided by using a statistically unique proof value in the generation of the protection values for a context (see 30.3 and 30.3.2). When the proof value of a hierarchy changes, saved object contexts belonging to that context can no longer be loaded into the TPM. The proof value for a context will change when its Primary Seed changes. Additionally, *ehProof* will change when either the SPS or EPS changes.

NOTE 1 In the reference implementation, *ehProof* is a non-volatile value from the RNG. It is allowed that the *ehProof* be generated by a KDF using both the EPS and SPS as inputs. If generated with a KDF, the ehProof can be generated on an as-needed basis or made a non-volatile value.

Saved contexts for all objects and sessions are invalidated on a TPM Reset. In the reference implementation, the encryption keys for contexts are changed by TPM Reset so previously saved contexts may no longer be loaded. Saved session contexts remain valid until the session is closed, or TPM Reset. If the *stClear* attribute of an object is SET, then saved contexts for the object are invalidated on either TPM Reset or TPM Restart (that is, any time the TPM does a Startup(CLEAR). If the *stClear* attribute of an object is CLEAR, then the saved contexts for that object are valid and may be loaded into the TPM until the next TPM Reset.

NOTE 2 In the reference design, when an object context is saved, the current value of *clearCount* is placed in the context. When the context is loaded, if the object is a *stClear* object, the value in the object is compared to the current value of *clearCount*. If they are not the same, then the context load fails.

Objects and sessions are not retained in TPM memory after a TPM2_Startup() and it is necessary for the TRM to save the contexts for any session or object that is to be useable after TPM Restart or TPM Resume.

NOTE 3 The TPM might lose power between a TPM2_Shutdown(TPM_SU_STATE) and the subsequent TPM2_Startup(). With respect to context preservation, the TPM behavior is defined to be the same whether the TPM loses power or not.

 Copyright © TCG 2006-2020

The structure of a saved context TPM2B_CONTEXT_DATA may be defined by the vendor, but a saved context is required to have its integrity and confidentiality protected by cryptographic means. Parts 3 and 4 of this specification implement the normative requirements for providing confidentiality and integrity protection for saved contexts. These protections are described in more detail in subsequent parts of this clause 30.

NOTE 4 The algorithms chosen for integrity and confidentiality protection of a saved context are vendor specific. However, the cryptographic strengths of the algorithms used are required to be the highest of any algorithm of the same type implemented on the TPM.

30.2 Context Data

30.2.1 Introduction

The data structure TPMS_CONTEXT returned by TPM2_ContextSave contains context metadata as well as the actual context TPM2B_CONTEXT_DATA. The context metadata contains:

- a sequence number,
- a handle, *savedHandle*, and

NOTE For Transient Objects, this *savedHandle* in a saved context data structure is not the same as the handle used by the TPM to reference loaded objects and by TPM commands to describe the object being operated on.

- a hierarchy selector.

The actual context contains:

- an integrity HMAC, and
- an encrypted data blob.

The structure of the metadata is normative. The internal structure TPMS_CONTEXT_DATA of the actual context is vendor specific. The encrypted data blob contains the data necessary to reconstruct the full object or session context in the TPM. The other fields are defined in the remainder of this clause 30.2.

The structure of the context contains both confidential and non-confidential data. This specification requires encryption of the confidential data. The TPMS_CONTEXT structure is normative. The structure of the enclosed TPMS_CONTEXT_DATA is vendor-specific, and its confidential data must be encrypted.

30.2.2 Sequence Number

New protection values are generated each time a context is saved. The protection values are an HMAC key, a symmetric key, and an initial value. The values are made unique by including a counter value in the generation process (see 30.3 and 30.3.2). The counter value used for the context is stored in the sequence number field of the context structure. Two counters are used for generating the sequence numbers. One counter is used for transient and sequence object contexts. A second counter is used for session contexts.

There are two counters used to provide sequence numbers. The counter (*objectContextID*) provides sequence numbers for Transient Objects. This counter is incremented each time an object context is saved. The counter (*contextCounter*) is used to provide sequence numbers for sessions and increments when a session context is created or loaded (its behavior is described in more detail in 30.5). When creating the context structure, the TPM sets the *sequence* parameter to the value of the counter used in the generation of the protection values for the context.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

When a context is loaded, (TPM2_ContextLoad()), the TPM checks that the *sequence* parameter is in a viable range before starting the operation. For an object, the viable range is any number that is less than the current value of the object sequence counter. For a session, the sequence number must also be less than the session sequence number, but it must also be greater that the sequence number minus the allowable range for session sequence number.

In the reference implementation, *objectContextID* is a 64-bit counter that is initialized to zero at startup and is expected to never overflow. The size is platform-specific.

EXAMPLE For purposes of this example, assume that the sequence counter value is only 16 bits and that the session counter indicates the last assigned session context had a value of $10\ 10_{16}$. It would then be an error if the *sequence* parameter in a loaded session context is greater than $10\ 10_{16}$. Assume further that the TPM only allows a range of 256 between session values (explanation in 30.5). Then it would be an error if the sequence parameter of the session in TPM2_ContextLoad() is less than $10\ 10_{16} – 01\ 00_{16} = 0F\ 10_{16}$; and the TPM will not load the context.

30.2.3 Handle

The *savedHandle* number for a context indicates the type of the context (object or authorization session). The type of the context is used to determine how to reconstruct the protection values for validation of the context. If the *savedHandle* value in the context is changed by software, the context will not load.

For a session, the same handle is assigned to the context whether the context is loaded in the TPM or in a saved context. That is, *savedHandle* is the same as the handle the TPM uses to refer to the session. A session handle will have an MSO of TPM_HT_HMAC_SESSION (02_{16}) or TPM_HT_POLICY_SESSION (03_{16}). The range of values in the handle index (the low-order three octets of the handle) is TPM dependent. In the reference implementation, the low order bits of the session context handles fall within a range from 0 to MAX_ACTIVE_SESSIONS – 1 and the TPM will generate an error and do no further processing of the context if the handle is outside of this range.

A *savedHandle* MSO of TPM_HT_TRANSIENT (80_{16}), indicates that the context is an Object or sequence object. For an object, the *savedHandle* parameter of the context structure does not indicate the handle value used by the TPM to reference the object (when a Transient Object context is not on the TPM, the TPM retains no information about that context). Therefore, the *savedHandle* value is not used for Transient Object contexts in the same way that it is used for session contexts. Instead, the *savedHandle* is used to indicate the type of the Transient Object context.

Three *savedHandle* values are defined for Transient Object contexts:

1) $00\ 00\ 00_{16}$ – indicates a Transient Object that does not have the *stateClear* property;

NOTE An Object has the *stateClear* property when *stClear* is SET in the Object or in any of its ancestor keys.

2) $00\ 00\ 01_{16}$ – indicates a sequence Object (see 32.4.5); and
3) $00\ 00\ 02_{16}$ – indicates a Transient Object that has the *stateClear* property.

EXAMPLE A sequence Object will have a 32-bit handle value of $80\ 00\ 00\ 01_{16}$.

If the *savedHandle* type is TPM_HT_TRANSIENT, the TPM will not generate or load a context with any other value besides the three values described above for the handle's index.

Objects that have the *stateClear* property are invalidated by Startup(CLEAR). To enforce this, the TPM will include *clearCount* in the integrity value of the Object.

TPM processing of contexts with *savedHandle* values of $80\ 00\ 00\ 00_{16}$ or $80\ 00\ 00\ 01_{16}$ is the same. The reason for differentiating sequence Objects is to identify the context for the convenience of the TPM

resource manager (TRM). The TRM needs to manage sequence objects differently from other Transient Objects. Because the context of a sequence object changes each time the sequence is updated, the context needs to be saved each time the context is used. The context of a Transient Object does not change on use. Therefore, the TRM can optimize by saving the Transient Object context only once.

30.2.4 Hierarchy

The hierarchy parameter of the context indicates which of the hierarchy proof values are used in the creation of the protection values for the context. For objects, this value is determined by the hierarchy of the object and may be TPM_RH_NULL for a Temporary Object. Sequence objects and sessions are in the Null hierarchy.

30.3 Context Protections

30.3.1 Context Confidentiality Protection

A symmetric block cipher is used to protect the confidentiality of a saved context. The algorithm is selected by the TPM vendor but is required to have the highest security strength of any symmetric block cipher implemented on the TPM.

When the context is created by TPM2_ContextSave(), the value of *sequence* is stored in the TPM2B_CONTEXT_SENSITIVE context before it is encrypted. When the context is loaded, the value of *sequence* is compared to the value in the loaded TPM2B_CONTEXT_SENSITIVE context after it is decrypted. If the values are not the same, then the TPM will enter failure mode as this is symptomatic of a specific type of power analysis attack.

The symmetric key and IV are regenerated when a context is loaded. It is required that the symmetric key and IV not be generated until the context integrity has been validated.

NOTE 1 This restriction prevents simultaneous power-analysis attacks on the integrity and encryption values of a context. Since the integrity is checked first, no attempt is made to create the symmetric key if the integrity check fails.

KDFa() is used to generate the symmetric encryption key and IV for context encryption. The parameters of the call are:

$$(symKey, symIv) \coloneqq \mathbf{KDFa}\,(hashAlg, hProof, vendorString, sequence, handle, bits) \quad (50)$$

where

hashAlg	a hash algorithm chosen by the vendor
hProof	the proof value associated with the hierarchy associated with the context
vendorString	a value used to differentiate the uses of the KDF
sequence	the sequence parameter of the TPMS_CONTEXT
handle	the handle parameter of the TPMS_CONTEXT
bits	the number of bits needed for a symmetric key and IV for the context encryption

NOTE 2 The value of *vendorString* is required to be different from any other label string used in a **KDFa**() call. The reference implementation uses "CONTEXT_ENCRYPT"

NOTE 3 The *nullProof* is used as the hProof value for a context in the Null hierarchy so that the encryption keys do not repeat and so that they change on each TPM Reset.

 Copyright © TCG 2006-2020

The key and IV produced in (50) are used to encrypt the object or session context

$$encContext \coloneqq \mathbf{CFB}_{symAlg}\,(symKey, symIv, context) \qquad (51)$$

where

$\mathbf{CFB}_{symAlg}$	symmetric encryption in CFB mode using a symmetric algorithm chosen by the TPM vendor
$symKey$	symmetric key from (50)
$symIv$	IV from (50)
$context$	the context being protected (a TPM2B_CONTEXT_DATA)

NOTE 4 The *size* field and the *buffer* field of *context* are encrypted.

30.3.2 Context Integrity Protection

The integrity of a saved context is protected by an HMAC using a hash algorithm selected by the TPM vendor. The hash algorithm chosen is required to have the highest security strength of any hash algorithm implemented on the TPM (see the description of TPM_PT_CONTEXT_HASH in TPM 2.0 Part 2).

The HMAC is constructed using the proof value associated with the hierarchy to which the object belongs. Since the proof value changes when the associated Primary Seed changes, HMAC validation for a previously saved context will fail when the associated Primary Seed changes; and that context may no longer be loaded. Other values in the HMAC computation serve to invalidate other context subsets without necessarily invalidating them all.

EXAMPLE The *clearCount* value is included in the HMAC of a context for an object with the *stClear* attribute so that the context will be invalidated on each TPM Restart as well as each TPM Reset.

The only TPM state change that invalidates all saved contexts is TPM Reset.

Sessions, Sequences, and Temporary Objects are in the “null” hierarchy.

The HMAC integrity computation for a saved context is:

$$contextHMAC \coloneqq \mathbf{HMAC}_{vendorAlg}\,(hProof, resetValue \,\{\, || \, clearCount\} \\ || \, sequence \, || \, handle \, || \, encContext) \qquad (52)$$

where

$\mathbf{HMAC}_{vendorAlg}$	HMAC using a vendor-defined hash algorithm
hProof	the hierarchy proof as selected by the hierarchy parameter of the TPMS_CONTEXT
resetValue	either a counter value that increments on each TPM Reset and is not reset over the lifetime of the TPM; or a random value that changes on each TPM Reset and has the size of the digest produced by vendorAlg
clearCount	a counter value that is incremented on each TPM Resume and may be incremented or set to zero on TPM Reset. This value is only included if the handle value is $80\ 00\ 00\ 02_{16}$.

NOTE the handle value is $80\ 00\ 00\ 02_{16}$ when the *stClear* attribute of the object is SET or when the *stClear* attribute is set in one of the object's ancestor keys.

 Copyright © TCG 2006-2020

sequence	the sequence parameter of the TPMS_CONTEXT
handle	the handle parameter of the TPMS_CONTEXT
$encContext$	the encrypted context blob

30.4 Object Context Management

When an object's context is saved, a copy of the object context is integrity protected, encrypted, and returned to the caller. The original context remains in the TPM and the TPM retains its handle. A saved object context may be reloaded into the TPM with TPM2_ContextLoad(). If the TPM has sufficient memory available, it will load the object and assign a handle. If other copies of the same object are in TPM memory, they are unaffected. An object context is only removed from TPM memory with TPM2_FlushContext(), deletion of the associated hierarchy seed, or TPM2_Startup().

The handle assigned to an object when it is loaded may not be assigned to any other TPM resource, object, or session. When the object is flushed from TPM memory, its handle may be assigned to another TPM resource when it is loaded or created.

Software may create as many copies of an object context as desired. When an object is not in TPM memory, it has no associated handle. If an object context is saved and subsequently reloaded, it is likely that a different handle will be assigned to the object.

When the Primary Seed is changed for the hierarchy associated with an object, all objects associated with that hierarchy are flushed from TPM memory. The TPM will no longer load saved contexts associated with the previous Primary Seed.

When an attempt is made to load an object or an object context (TPM2_Load(), TPM2_CreatePrimary(), TPM2_LoadExternal() or TPM2_ContextLoad()) and the TPM does not have sufficient RAM to hold the object, the TPM will return TPM _RC_OBJECT_MEMORY or TPM _RC_MEMORY. This warning code is normally handled by the TRM. It indicates that an object or a session needs to be unloaded from TPM memory before the command can complete. If the TPM returns TPM_RC_OBJECT_MEMORY, it indicates that an object must be flushed from TPM memory. If the TPM returns TPM_RC_MEMORY, then it is possible that removal from TPM RAM of either an object or a session would allow the command to complete.

When a command references a persistent object, the TPM may move the object from NV into an object slot. If no slot is available, the TPM will return TPM_RC_OBJECT_MEMORY.

An implementation is allowed to use an object slot for temporary memory in execution of TPM2_Import() and return TPM_RC_OBJECT_MEMORY if a slot is not available.

If the TPM uses an object slot for temporary memory, the slot will be freed at the end of the command in which the slot was allocated.

If a TPM receives Shutdown(STATE) before the _TPM_Init, then the saved object contexts will continue to be usable after a TPM Restart or TPM Resume. An exception is that an object may be created with the *stClear* attribute. If this attribute is SET in an object or an ancestor of an object, then the saved context will be invalidated on TPM Restart. All saved object contexts are invalidated by TPM Reset.

30.5 Session Context Management

A session context is created by TPM2_StartAuthSession(). The context associated with a session is unique. That is, the data describing the session's state may be either on the TPM or saved off the TPM, but not both. Further, a saved session context may only be loaded once. These limitations on the session context are intended to prevent possible attacks based on replay of authorizations.

 Copyright © TCG 2006-2020

The handle associated with a session does not change as long as the session is active. The session is active until closed by the *continueSession* flag being FALSE or until the session context is flushed from the TPM by TPM2_FlushContext().

The nominal implementation uses a volatile counter (*contextCounter*) that increments each time a session is created or context loaded. This count value is assigned to the created or loaded session context and serves as a version number for the session context. If the session context is saved and reloaded, it is assigned a new version number. *contextCounter* is saved by Shutdown(STATE) and reset on TPM Reset.

The TPM maintains a database of concurrent sessions so that it can validate that a reloaded session context is the most recent version. It is required that the TPM be able to ensure that the restored context is the correct context regardless of the number of contexts created.

The size of *contextCounter* affects the size of the memory required for tracking each of the contexts. It is therefore desirable that the counter only be large enough for the majority of applications, meaning that it will not be large enough for all applications. In those applications, a method is required to handle counter rollover.

One scheme for handling rollover is to maintain an even/odd interval. If, for example, a nonce were being used for each interval, then the TPM could maintain two nonces, one to be used when the MSb of the volatile counter is 0 and the other when the MSb is 1. When the counts of all the sessions have the same MSb, then a new nonce can be created for use when the MSb changes. This scheme works unless a session has a long lifetime. That is, if the session is created when the MSb is 0, and the session is still active when the counter reaches its maximum value with all bits equal 1, then the context with an MSb of 0 will need to be discarded.

Rather than have the old session be automatically flushed, the TPM provides an indication that it is reaching its limit and that one or more saved session contexts need to have their *sequence* number updated to the current interval in preparation for the context counter rollover.

The indication that the context counter is approaching its limit is provided when an authorization session is created or loaded. If the creation or loading of a session would make it impossible for the TPM to bring all contexts into the current interval, then it would return an error (TPM_RC_CONTEXT_GAP) and not create or load the new session. On receiving this error, the management software either would explicitly flush old session contexts or would load the old session contexts to update their associated counter values.

When the TPM returns TPM_RC_CONTEXT_GAP, it will not allow an authorization session to be created and it will only allow the oldest authorization session to be loaded. When the oldest session is loaded, its *sequence* number is updated. It may be used or saved with its new *sequence* number.

NOTE The TPM must provide the indication of the session-tracking limit being reached before the maximum count is reached. If there are three sessions in the 'odd' interval and the end of the 'even' interval is being reached, then the TPM must indicate the limit while there are still three available session sequence numbers in the 'even' interval. This allows the sessions in the 'odd' interval to be loaded and saved with an 'even' interval session sequence number and with no session in the 'odd' interval so that a new 'odd' interval identifier can be created.

Session contexts in TPM RAM are flushed on any TPM2_Startup(). Saved session contexts are not invalidated and may be reloaded after a TPM Restart or TPM Resume. Saved session contexts are invalidated on a TPM Reset.

30.6 Eviction

Eviction is the process of removing the context associated with an object or session from TPM RAM to allow for other sessions or objects to be loaded or created. Saving a session context removes the majority of the session context from TPM RAM. Saving an object context does not remove it from TPM

 Copyright © TCG 2006-2020

memory. When applied to an object, TPM2_FlushContext() will remove it from the TPM RAM but not invalidate the saved contexts of that object. When applied to a session, TPM2_FlushContext() will invalidate the session whether its context is in TPM RAM or saved.

An object may be copied to persistent TPM NV memory with TPM2_EvictControl(). When made persistent, TPM2_FlushContext() and TPM2_Startup(TPM_SU_CLEAR) have no effect on the persistent copy of the object.

A session may not be made persistent.

Use of TPM2_EvictControl() requires either Owner Authorization or Platform Authorization. An object made persistent using *ownerAuth* may be evicted from persistent memory using either Owner Authorization or Platform Authorization. An object made persistent using Platform Authorization may only be evicted from persistent memory using Platform Authorization.

30.7 Incidental Use of Object Slots

In most cases, the TRM will explicitly load and unload (flush) objects from the TPM's object memory. In three cases, the TPM will make use of object slots as a side effect and the TRM needs to deal with potential resource issues that may arise. The three cases are: TPM2_Import(), use of persistent objects, and _TPM_Hash_Start.

TPM2_Import() allows an implementation to use an object slot for its "scratch" memory while operating on the import blob. When the command completes the slot will be available. An implementation that uses this option may return TPM_RC_OBJECT_MEMORY if a needed slot is not available. This return code is in the group of response codes that are expected to be handled by the resource manager.

When a handle references a persistent object, a TPM implementation is allowed to return TPM_RC_OBJECT_MEMORY if an object slot is not available. This allows the TPM to keep the persistent image of the object in a compressed form and decompress it into an object slot for efficient processing. The version of the persistent object held in an object slot will be removed when the command completes.

When the TPM receives _TPM_Hash_Start, it will unconditionally create an Event Sequence context. If an object slot is available, the TPM will use the available slot. If an object slot is not available, the TPM will flush an arbitrary object context and use that slot. At the end of the event sequence (_TPM_Hash_End), the slot used for the Event Sequence will be vacant. The TRM should be aware that the _TPM_Hash_Start sequence may cause loss of a loaded object.

31 Attestation

31.1 Introduction

Attestation is the action of having the TPM sign some internal TPM data. Confidence in the attestation is related to the confidence in the key that is used to sign. The highest confidence is provided by a *fixedTPM*, restricted signing key that is created on a TPM with a certificate from the TPM manufacturer.

The TPM may be used to attest to several different types of data:

- PCR data – TPM2_Quote()
- *Clock* and *Time* data – TPM2_GetTime()
- Audit digests – TPM2_GetCommmandAuditDigest() and TPM2_GetSessionAuditDigest()
- Other TPM Objects – TPM2_Certify()

For all of these commands, the TPM produces a standard attestation structure and appends the command-specific data. The resulting data block is then hashed and signed by the selected signing key. The selected key may be any key that has the *sign* attribute SET. If the signing key is unrestricted, then the caller may indicate the signing scheme to be used. If the signing key is restricted, the TPM will return an error (TPM_RC_SCHEME) unless the scheme selector in the attestation command is TPM_ALG_NULL.

31.2 Standard Attestation Structure

The contents of the standard attestation structure are described in Table 30.

Table 30 — Standard Attestation Structure

Parameter	Type	Description
magic	TPM_GENERATED	This unique value (TPM_GENERATED_VALUE) occurs as the first octets in any TPM-generated attestation structure. This field is used to prevent use of a restricted signing key to sign a forgery of an attestation. A TPM will not allow a restricted signing key to sign any external data if that data starts with this unique value. The way that the TPM enforces this restriction is that a TPM will not use a restricted key to sign a digest that the TPM did not produce. Since the TPM produced the digest, it can ensure that any external data did not start with this value.
type	TPMI_ST_ATTEST	This identifies the type of the attestation structure and indicates the contents of the *attested* parameter.
qualifiedSigner	TPM2B_NAME	This is the Qualified Name of the key used to sign the attestation data. A key that can be duplicated may be signing in different locations and this Qualified Name allows the Verifier to determine the environment in which the signature was produced.
extraData	TPM2B_DATA	external info supplied by caller (often in *qualifyingData* parameter) NOTE A TPM2B_DATA structure provides room for a digest and a method indicator to indicate the components of the digest. The definition of this method indicator is outside the scope of this specification.
clockInfo	TPMS_CLOCK_INFO	The values of *Clock*, *resetCount*, *restartCount*, and *Safe*
firmwareVersion	UINT64	This TPM-vendor-defined value changes when the firmware on the TPM changes, if that change is meaningful to the security of the TPM.
[type]attested	TPMU_ATTEST	the type-specific attestation information

 Copyright © TCG 2006-2020

31.3 Privacy

The attestation block contains information that could allow cross correlation of attestation values. The combination of a *firmwareVersion* and *clockInfo* could be used to identify that two attestations were signed by keys on the same TPM. This correlation is possible because the combination of *resetCount*, *restartCount*, and *firmwareVersion* could be unique. Even if the combination is not unique for all TPM, an imperfect correlation may be adequate for certain types of activity tracking.

The TPM prevents such tracking by adding obfuscation values to the reported values of *resetCount*, *restartCount*, and *firmwareVersion*. This obfuscation value is different for each key and TPM (see 36.7). Although the values are obfuscated, they do not lose any of their usefulness for indicating changes to the values. While the absolute values are not visible in the attestation, it is still possible to look at attestations signed by the same key and determine how many times the TPM was reset or restarted between the attestations and to see the delta in the firmware version number (if any).

It is sometimes necessary to have the non-obfuscated values of the *clockInfo* and *firmwareVersion* included in an attestation. Support for this is provided by allowing signing keys in the Endorsement hierarchy. When a key in the Endorsement hierarchy signs an attestation, no obfuscation is applied. The underlying presumption is that the TPM's Privacy Administrator controls the Endorsement hierarchy and it is possible, through policy, to limit the use of keys in that hierarchy so that authorization from the Privacy Administrator is always required.

31.4 Qualifying Data

Each of the attestation commands has a parameter called *qualifyingData*. This parameter is not interpreted by the TPM and may contain any data chosen by the caller. The most common use of this parameter is expected to be as a nonce to ensure "freshness" of an attestation.

31.5 Anonymous Signing

If an anonymous scheme (TPM_ALG_ECDAA) is used for signing in any attestation command, the *qualifiedSigner* parameter will be an Empty Buffer.

NOTE 1 If the *qualifiedSigner* field was properly populated (not the Empty Buffer), then the unique identity of the signing key would be disclosed.

For TPM2_Certify() using an anonymous signing scheme, both the *qualifiedSigner* and *qualifiedName* of the certified key are set to an Empty Buffer.

NOTE 2 If the *qualifiedName* field was not cleared, then it would be possible to establish a hierarchical relationship between to certified objects. This is not desirable for an anonymous scheme.

31.6 X.509 Certificate Signing

TPM2_CertifyX509() signs an X.509-formatted certificate. Prior to constructing and signing an X.509 certificate, TPM2_CertifyX509() verifies that the key-to-be-certified is loaded in the TPM, and that some of the permissions in the key's proposed X.509 certificate are compatible with the key-to-be-certified.

A typical use of TPM2_CertifyX509() is the enrollment of any TPM key into an X.509 Public Key Infrastructure. TPM2_CertifyX509() signs an X.509 formatted certificate describing the TPM key, rather than enabling the TPM key to self-certify by creating an X.509 formatted Certificate Signing Request (CSR). This is because a CSR doesn't provide a way for a TPM to communicate to a Certification Authority that the TPM key is protected by a TPM, or the restraints on the TPM key that are enforced by the TPM. The X.509 formatted certificate signed by the TPM is inspected by a Certification Authority prior to the CA signing its own certificate describing the operations on the key that are approved by the CA. A simpler CA will use conventional X.509 methods to just verify the TPM's certificate and verify the X.509

 Copyright © TCG 2006-2020

certificate of the key that signed the TPM's certificate. A more sophisticated CA that understands TPMs will also interpret the TPM certificate's Extensions element, which describes the certified key's detailed TPMA_OBJECT attributes and indicates precisely what operations a TPM can and cannot perform on the certified key.

In a typical usage of TPM2_CertifyX509():

- First, the CA (or its proxy) loads a certifying signing key in the TPM. The certifying signing key is typically a key with the x509Sign attribute SET.

- Next, the CA uses the certifying key with TPM2_CertifyX509() to certify a TPM key . The DER-encoded partialCertificate parameter for TPM2_CertifyX509() describes the validity time for the certificate as well as the X.509 Name for the certifying and certified keys. Additionally, partialCertificate is required to contain a KeyUsage in the Extension field and may contain a TPMA_OBJECT Extension. TPM2_CertifyX509() verifies that the key is compatible with approved operations, constructs a complete X.509 RFC 5280-defined certificate, and signs that complete certificate.

- TPM2_CertifyX509() returns the part of the complete X.509 certificate that was constructed by the TPM, plus the TPM's signature over the complete certificate. This data and partialCertificate are assembled outside the TPM into a complete X.509 RFC 5280-defined signed certificate for inspection by the Certification Authority using conventional X.509 tools.

- Finally, the Certification Authority recertifies the TPM key using the CA's normal certifying key, for consumption by entities that trust the CA.

Certification Authorities should be wary of certificates signed by TPM2_CertifyX509() with keys that do not have the x509sign attribute SET, because an X.509 certificate can be signed using TPM2_Sign(). In that case, the TPM will not have verified that the certified key is loaded in the TPM and will not have verified that the certified key is compatible with the X.509 certificate. Nevertheless, an X.509 certificate signed by TPM2_CertifyX509() with an ordinary signing key or a restricted signing key may be acceptable when the CA trusts the entity controlling usage of that signing key: the CA itself may have exclusive control over the signing key, for example.

An x509sign key is even more restricted than a restricted key: a restricted key won't use TPM2_Sign() to sign any data that starts with the "magic" parameter, and an x509sign key won't use TPM2_Sign() to sign any data at all. Hence the command TPM2_CertifyX509() is the only way that an x509sign key can sign an X.509 certificate. An x509sign key will also sign any of the non-X.509 certification commands (e.g., TPM2_Certify, TPM2_CertifyCreation, TPM2_NV_Certify), which sign data that start with the TCG "magic" value. This enables an x509sign key to be an Attestation Key with a certificate proving that the x509sign key is bound to a single TPM and is safe because none of the certification commands sign data that could masquerade as a fraudulent certificate.

TPM2_CertifyX509() verifies that a key-to-be-certified is compatible with permissions granted by the X.509 certificate. Broadly speaking, the TPM verifies that the private key can decrypt if the certificate says the key is approved for decryption and verifies that the private key can sign if the certificate says the key is approved for signing. The TPM verifies that a key has its fixedTPM attribute SET if the certificate approves the key for nonrepudiation/contentCommitment operations, because only the TPM that has a particular fixedTPM key can use that particular key.

TPM2_CertifyX509() cannot guarantee that a key will perform only the operations approved by an X.509 certificate. A TPM cannot control operations on the public part of a key and doesn't usually know why is key is being used, whereas a certificate can approve operations on the public part of a key and can approve the objective of operations on a key. Relying parties are cautioned that not all of the information in a certificate signed using TPM2_CertifyX509() is validated by the TPM. The TPM validates the public key of the target, the KeyUsage, and the TPMA_OBJECT extended attributes.

Some partialCertificate inputs to TPM2_CertifyX509 cannot be verified by the TPM but must be present because they are necessary to create a signature over an X.509 certificate. One such input is the certifying signing scheme OIDs that are necessary to create the signature. The caller does not need to supply OIDs if the TPM is able to generate the OIDs for the certifying signing scheme. However, there are so many OIDs that the TPM is unable to generate all possible OIDs, and some OIDs have not yet been assigned. Thus, the caller must supply the OIDs for the certifying signing scheme if the TPM is unable to generate them. Should the caller supply OIDs, they take precedence over any OIDs that the TPM would have assigned.

32 Cryptographic Support Functions

32.1 Introduction

In TPM 1.2, the cryptographic primitives were not exposed for general purpose use. For example, the RSA engine could not be used for exponentiation. This specification provides commands that allow access to the primitive cryptographic processes of the TPM.

One assumption in TPM 1.2 was that the host processor usually had much greater performance than the processor used for the TPM so there was no point in having the TPM do something that the host could do much faster. In addition, TPM 1.2 was a passive device with limited bandwidth. While it is true that the host processor will usually have more capability than the TPM, this will not be true in all cases. In fact, on some systems, the main processor will be able to switch execution environments and perform the TPM operations. In others, the TPM may be built around a cryptographic coprocessor that has significantly greater processing capability for cryptographic operations than the host. These higher performance implementations will not be performance-limited by being attached to the system with a low-bandwidth interface. These performance differences mean that exposure of the cryptographic primitives of TPM 2.0 makes more sense that it did in TPM 1.2.

Another reason to make the cryptographic primitives available is that not all software will implement all the algorithms that may be in the TPM. For example, a BIOS may not implement the RSA algorithm but would want to check the RSA signature of some code.

This clause describes the commands and methods that may be provided by a TPM compliant to this specification.

32.2 Hash

TPM2_Hash() will create a digest of a block of data using the indicated hash algorithm. If the amount of data to be hashed exceeds that input buffer size of the TPM, then a hash sequence is used (see 32.4).

If the data used to create the digest does not have TPM_GENERATED_VALUE as its first octets, then the response to TPM2_Hash() or TPM2_SequenceComplete() will contain a ticket indicating that the digest may be signed with a restricted signing key.

NOTE The creation of the ticket may be suppressed by using TPM_RH_NULL as the hierarchy parameter in TPM2_Hash() or TPM2_SequenceComplete().

32.3 HMAC

TPM2_HMAC() will compute an HMAC over a block of data using a TPM-resident value for the HMAC key. In this command, the handle parameter is required to reference an object with a *type* of TPM_ALG_KEYEDHASH with the *sign* attribute SET.

32.4 Hash, MAC, and Event Sequences

32.4.1 Introduction

When the amount of data to be included in a digest cannot or will not be sent to the TPM in one of the atomic hash/HMAC commands (TPM2_Hash(), or TPM2_HMAC()) then a sequence of commands may be used to provide incremental updates to the digest.

A sequence is started with either TPM2_HashSequenceStart() or TPM2_HMAC_Start(); increments of data are added to the sequence digest(s) using TPM2_SequenceUpdate(); and

TPM2_SequenceComplete() or TPM2_EventSequenceComplete() is used to complete a sequence. TPM2_SequenceComplete() and TPM2_EventSequenceComplete() may also provide the last data to be included in the sequence digest(s).

Three types of sequences are defined:

1) hash
2) Event
3) HMAC

32.4.2 Hash Sequence

In a hash sequence, the TPM will perform a hash over all the data in the sequence using the selected algorithm.

TPM2_SequenceComplete() completes the hash sequence and returns a digest of the data. Additionally, if the data used to create the digest did not start with TPM_GENERATED_VALUE, then a ticket is produced indicating that the digest may be signed with a restricted key.

A hash sequence is:

a) TPM2_HashSequenceStart() (*hashAlg* is a supported hash algorithm), followed by
b) TPM2_SequenceUpdate() (zero or more), followed by
c) TPM2_SequenceComplete()

32.4.3 Event Sequence

For an Event Sequence, the TPM will potentially create multiple digests over the data (a digest for each PCR bank). TPM2_EventSequenceComplete() is used to complete the sequence and return a list of digests; and, If a PCR handle is provided, each digest is extended into the corresponding PCR bank.

EXAMPLE If a TPM implements both a SHA1 and a SHA256 bank, then the list will contain two digests.

An Event Sequence is:

a) TPM2_HashSequenceStart() (*hashAlg* is TPM_ALG_NULL), followed by
b) TPM2_SequenceUpdate() (zero or more) followed by
c) TPM2_EventSequenceComplete() (will do an Extend if *pcrHandle* is a PCR and not TPM_RH_NULL)

32.4.4 HMAC Sequence

For an HMAC sequence, the TPM will use the indicated key as the HMAC key and perform an HMAC computation over the data of the sequence using the specified hash algorithm.

TPM2_SequenceComplete() completes the HMAC sequence and returns the HMAC value.

NOTE The response for TPM2_SequenceComplete() also has a *validation* parameter. This parameter is used for a hash sequence to indicate if the digest is safe to sign with a restricted key. This parameter is not used for an HMAC sequence so the TPM will set the *validation* parameter to a NUL Ticket

An HMAC sequence is:

 Copyright © TCG 2006-2020

a) TPM2_HMAC_Start() (*hashAlg* is a supported hash algorithm), followed by

b) TPM2_SequenceUpdate() (zero or more) followed by

c) TPM2_SequenceComplete()

32.4.5 Sequence Contexts

Sequences involve hashing of data and the intermediate hash state must be retained by the TPM in a protected location. This intermediate state is kept in a vendor-specific structure that may occupy an object slot on the TPM.

A sequence context is assigned a handle so that it may be saved and restored like any Transient Object. Its properties are not identical to other Objects because the sequence context is updated on each use. In addition, unlike other Objects, the public portion of a sequence is not readable with TPM2_ReadPublic(). A sequence context can be replayed if one has the authorization for the sequence.

If an authorization or audit for a sequence object requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

When TPM2_EventSequenceComplete() or TPM2_SequenceComplete() completes successfully, the sequence context is flushed from the TPM.

A sequence is exempt from dictionary attack protection and authorization failures will not cause the TPM to enter lockout.

32.5 Symmetric Encryption

TPM2_EncryptDecrypt() is defined for symmetric encryption and decryption of blocks of data. Support for this command in a TPM may cause the TPM to be subject to different jurisdictions' legal import/export controls than would apply to a TPM without these commands.

The command supports chaining of encryption so that the encryption/decryption may be done incrementally as the data arrives or to handle the cases where the block of data is larger than will fit into a single TPM buffer.

32.6 Asymmetric Encryption and Signature Operations

The annexes to this TPM 2.0 Part 1 contain descriptions of the cryptographic encryption/decryption and signature primitives that are defined for each of the asymmetric algorithms supported by the specification.

 Copyright © TCG 2006-2020

33 Locality

In some systems, accesses to the TPM are segregated by privilege level. The interface to the TPM may be able to discriminate the different privilege levels and provide an indication to the TPM when the access is at a privilege level other than the default level.

The indication of privilege level can be used in access control policy to ensure that the operation on an object is occurring at the right level. The privilege level of a command is called its Locality.

The method by which the TPM interface determines the Locality of an access is system-dependent. The TPM interface provides a Locality indication to the TPM each time the TPM is accessed. The contents of the command or response buffer are not changed by the Locality indication.

The definition of the modifier is platform-specific. Depending on the platform, the modifier could be a special bus cycle or additional input pins on the TPM. One example would be special cycles on the Low Pin Count (LPC) bus that inform the TPM it is under the control of a process on the PC platform. The assumption is that spoofing the modifier to the TPM requires more than just a simple hardware attack and would require expertise and possibly special hardware.

The locality value is represented as a byte and locality values have two separate representations. Localities 0 through 4 are represented as bits in the byte with $0000\ 0001_2$ representing locality 0 and $0001\ 0000_2$ representing locality 4. This representation allows multiple localities to be represented in a single byte as long as the localities are in the range of 0-4. This representation of locality is compatible with previous versions of this specification.

A second representation is for localities above 4. These are called *extended localities*. For extended localities, the locality byte is an integer value representing the locality. Because of the format for localities 0-4, the first extended locality is 32. The range of extended localities is 32-255. The locality value may indicate only one extended locality at a time.

NOTE Locality 5 through 31 cannot be selected.

34 Hardware Core Root of Trust Measurement (H-CRTM) Event Sequence

34.1 Introduction

A process that puts the system in a known state running known code creates the starting point for a chain of trust. A computer system reset puts the processor and chipset into a known state, and the processor (the root of trust for measurement) begins executing code provided by the platform manufacturer. This initial code is the core root of trust for measurement (CRTM). It is code that must be trusted as there is no way to tell what that code is other than to rely on the manufacturer. Usually, one of the actions of the CRTM is to extend a PCR with a value that represents the identity of the CRTM. This boot process starts the chain of trust with two different roots that are usually from different sources: the RTM from a CPU vendor and a CRTM from a platform manufacture.

Some system implementations support an alternative method of starting a chain of trust that makes the CPU the CRTM. For this method, the CPU is placed in a known state and measures the code that it will run. Before being measured, this code is protected so that it cannot be tampered with and there is assurance that the code that is measured is the code that is executed. Since the CPU is both executing the measured code and measuring it, it is both the RTM and the CRTM. This is called a hardware-based core root of trust for measurement or H-CRTM.

The TPM supports an H-CRTM by providing special interface indications that allow the TPM to determine when it is receiving data from the RTM acting as CRTM. These indications are:

- **_TPM_Hash_Start** – sent by the RTM to indicate the start of a H-CRTM Event Sequence. The TPM will initialize an H-CRTM Event Sequence context. The H-CRTM Event Sequence context contains hash state for each bank of PCR. This indication is only allowed from the RTM when it has been put into a known "good" state as defined by the RTM manufacturer. There is only one _TPM_Hash_Start per H-CRTM Event Sequence.
- **_TPM_Hash_Data** – sent by the RTM to update the digests in the H-CRTM Event Sequence contexts with H-CRTM data. An H-CRTM Event Sequence may have zero or more _TPM_Hash_Data indications.
- **_TPM_Hash_End** – sent by the RTM to indicate the end of the H-CRTM Event Sequence. On receipt of this indication, the TPM will take actions that are dependent on whether the H-CRTM occurred before or after TPM2_Startup(). The actions taken as the result of this indication will always include initialization of at least one PCR followed by a PCR being extended with the H-CRTM data.

During an H-CRTM sequence, if any indication other the _TPM_Hash_Data occurs between the _TPM_Hash_Start and _TPM_Hash_End indications (including receipt of a command), then the H-CRTM Event Sequence is abandoned, the H-CRTM Event Sequence context is flushed, and no change to any PCR occurs.

NOTE The interface may be designed such that it is not possible to interrupt this sequence.

34.2 Dynamic Root of Trust Measurement

When an H-CRTM occurs after TPM2_Startup() it is called the dynamic root of trust for measurement (D-RTM).

NOTE There is no special designation for when the H-CRTM occurs before TPM2_Startup()

NOTE The D-RTM sequence may be repeated one or more times after TPM2_Startup. On each invocation of the D-RTM sequence, the RTM must be in the same known state.

For D-RTM, the TPM will initialize one or more PCR to zero and then extend PCR[17] in each bank with the H-CRTM data accumulated in the H-CRTM Event Sequence.

 Copyright © TCG 2006-2020

$$\text{PCR}[17][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(0\ldots0 \,||\, \mathbf{H}_{hashAlg}(hash_data)) \tag{53}$$

Where

$hash_data$	all the octets of data received in _TPM_Hash_Data indications

The PCR that are initialized and extended as a result of a D-RTM event are specified in a platform-specific TPM specification.

34.3 H-CRTM before TPM2_Startup() and TPM2_Startup() without H-CRTM

If the H-CRTM sequence occurs before TPM2_Startup(), then only PCR[0] will be affected. When _TPM_Hash_End is received, the TPM will complete the Event Sequence digests. It will then initialize PCR[0] to 4 and Extend the H-CRTM Event Sequence data. The value 0…4 represents evidence that the initial measurement was from an H-CRTM.

$$\text{PCR}[0][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(0\ldots04 \,||\, \mathbf{H}_{hashAlg}(hash_data)) \tag{54}$$

where

0…04	denotes a numeric value of 4 with high-order bits of 0 to make the value the size of a digest computed with *hashAlg*
$hash_data$	all the octets of data received in _TPM_Hash_Data indications

If PCR[0] is initialized by an H-CRTM event before TPM2_Startup(), then TPM2_Startup(CLEAR) will not change the value of PCR[0]. Otherwise, TPM2_Startup(CLEAR) will set PCR[0] to the locality of the TPM2_Startup() command.

If there is an H-CRTM event before a TPM2_Startup(CLEAR), there must be an H-CRTM event before a subsequent TPM2_Startup(STATE). The locality of the TPM2_Startup(STATE) is not checked against the locality of the previous TPM2_Startup(CLEAR)

If there is no H-CRTM event before TPM2_Startup(CLEAR), there must be no H-CRTM event before a subsequent TPM2_Startup(STATE) and the TPM2_Startup(STATE) must have the same locality as the previous TPM2_Startup(CLEAR).

35 Command Audit

The command audit mechanism allows the TPM owner to create a verifiable log of each execution of selected commands.

TPM2_SetCommandCodeAuditStatus() is used either to change the list of commands being audited or to change the audit hash algorithm (it cannot change both in the same command). This command requires either Platform Authorization or Owner Authorization. The selection may change at any time.

NOTE 1 It is anticipated that a small number of commands will be selected for audit, most likely those commands that provide identities and control of the TPM. However, there are few restrictions on which commands may be audited.

The audit log, the list of executed TPM commands and responses, is maintained outside the TPM by an untrusted party. Enabling the audit function of a TPM does not guarantee that the log will be properly maintained. The TPM audit function simply provides a means to determine if the log was properly maintained.

It is not necessary to continuously maintain the audit log in order to use the audit capability. When an audit log is started, the current contents of the audit digest register can be read to establish the starting value for the log. At the end of the audit interval, the audit digest register can be read again and the contents of the audit log over the audit interval can be verified.

An audit can be used to track use of keys and, therefore, is potentially privacy sensitive. For this reason, the privacy administrator of the TPM must authorize access to the audit digest register. Authorization from the privacy administrator is expressed using Endorsement Authorization.

The update of the audit digest register occurs when the command completes successfully and the response has been created. The command audit update is:

$$audit_{new} \coloneqq \mathbf{H}_{auditAlg}(audit_{old} \,||\, cpHash \,||\, rpHash) \tag{55}$$

where

$\mathbf{H}_{auditAlg}$	hash function using the currently selected audit hash algorithm
$audit_{old}$	the previously computed audit digest
$cpHash$	the command parameter hash using the audit hash
$rpHash$	the response parameter hash using the audit hash

NOTE 2 Clause 18.7 describes the process for computing *cpHash* and clause 0 describes the process for computing the *rpHash*.

The audit mechanism uses two components: an audit digest register and an audit counter. The audit counter is a non-volatile register that counts the number of audit logs that are created. If the audit digest register contains all octets of zero when an audit event is recorded, then a new audit log is being created and the audit counter is incremented.

An audit log ends and the audit digest is cleared when the command TPM2_GetCommandAuditDigest() returns a signature.

NOTE 3 The audit counter is incremented when the new log starts so that a missing log cannot be dismissed as being irrelevant. Because a new audit log is started only when an auditable event occurs, any missing log is suspect.

 Copyright © TCG 2006-2020

The audit counter is non-volatile and is reset to zero by TPM2_Clear(). The audit digest register is reset when an unanticipated power event occurs (that is, loss of TPM power without an orderly shutdown). The audit digest is preserved over any orderly shutdown.

The audit digest register is reset by a TPM2_SetCommandCodeAuditStatus() that changes the audit digest algorithm *auditAlg*.

An audit report structure contains the current value of the audit digest register and the value of the audit counter.

NOTE 4 The signed audit structure is a TPM2B_ATTEST structure that contains other qualifying information about the signing environment.

Because the audit mechanism utilizes NV memory, endurance may be a factor. The endurance requirements of the audit mechanism are platform-specific.

NOTE 5 The command audit session counter is incremented on the first auditable command in a session. This should be infrequent so the endurance of the counter is not likely to be a major issue.

When the TPM is in Failure mode, command audit is not functional and command audit of TPM2_GetTestResult() and TPM2_GetCapability() will not occur.

TPM2_SetCommandAuditStatus() is audited when it changes the list of audited commands. It is not possible to disable audit of this command. If TPM2_SetCommandAuditStatus() is used to change the audit hash algorithm, then the command is not audited and evidence of this operation is provided by the change in the hash algorithm reported when the command audit value is read.

 Copyright © TCG 2006-2020

36 Timing Components

36.1 Introduction

The TPM has timing components for use in time-stamping of attestations and for gating policy

Time is a free-running hardware value that is not under software control. *Time* advances when the *Time* circuit is powered and is reset to zero when power to the *Time* hardware is lost.

NOTE 1 Typically, the *Time* hardware will be powered down when the rest of the TPM is powered down.

Clock is a value that is derived from *Time* and advances as *Time* advances. *Clock* may be advanced in order to bring it into alignment with real time. However, *Clock* may not be set back except by installing a new owner.

The *resetCount* and *restartCount* values allow detection of power loss that could cause discontinuities in the time recorded by *Clock*. The Safe flag indicates whether *Clock* might have been wound backwards, in which case the current *Clock* value would be unsafe. The timing components are exposed through commands that:

- read the value of *Clock*, *Time*, *resetCount*, and *restartCount* (TPM2_GetTime());
- time-stamp externally provided data using a signature key and *Clock*, *resetCount*, and *restartCount* (TPM2_GetTime(), TPM2_Quote(), TPM2_Certify(), and other restricted signing operations);

NOTE 2 TPM2_ReadClock() returns uncertified (not signed) values. TPM2_GetTime() returns a structure and an optional signature over the data. TPM2_ReadClock() is used by the OS to manage the timing resources of the TPM and TPM2_GetTime() is for attestation of time and is under control of the privacy administrator.

- allow *Clock* to be adjusted forward (TPM2_SetClock());
- allow the rate of advance of *Clock* to be adjusted (TPM2_ClockRateAdjust()); and
- allow objects to be lifetime-limited using authorization policy expressions that reference *Safe*, *Clock*, *Time*, *resetCount*, and *restartCount* (TPM2_PolicyCounterTimer()).

Potential use cases for the TPM timing components include:

- lifetime limits for keys when certificate revocation is impossible or undesirable;
- time-limited delegation of rights (such as, the right to use or duplicate a key for 1 hour);
- time-stamping of security event logs to ensure that events cannot be forged in the past;
- boot-counter stamping of event logs to ensure that a log associated with a particular reboot cannot be deleted without leaving a trace;
- boot-counter/PCR-counter stamping of keys to indicate they were created during OS installation;
- time-stamping of attestation values as an alternative to the use of a nonce in online protocols; and
- indication of whether a TPM/platform has rebooted since last checked.

Clock is *not* designed to be a replacement for other online or local time sources and is not appropriate for all uses. Later clauses describe the behavior of timing resources and their specific security properties. Implementers and relying parties should understand the limitations before using these features.

 Copyright © TCG 2006-2020

36.2 Time

Time is a 64-bit value that contains the time in milliseconds that the circuit providing *Time* has been powered.

NOTE Depending on the frequency of the TPM oscillator and the setting of the frequency divisor (TPM2_ClockRateAdjust()), the rate at which *Time* advances may be in error by as much as 32.5%.

Time is unaffected by TPM2_ClockSet().

The circuit providing *Time* may be powered independently from the rest of the TPM. However, *Time* must be powered whenever the TPM is powered. The *Time* hardware needs to provide a reliable indication that it has lost power or has been reset. *Time* should not be reset unless the TPM requires a _TPM_Init indication before resuming operation.

Time need not advance continuously when powered. The *Time* hardware is required to provide a reliable indication if *Time* has stopped advancing.

36.3 Clock

36.3.1 Introduction

Clock is a time value that can be advanced but never rolled back. It may increment in volatile memory. If so, it is periodically written to NV memory.

A non-orderly shutdown may cause a write to NV memory to be missed. Other values that are written to NV on an orderly shutdown will be advanced to a known safe value on the next startup. However, Clock is not advanced because power outages would cause the clock to be advanced to a time in the future and it could not be adjusted back to an accurate value. To indicate that a value reported in Clock may be a repeat of a previously reported value, a flag (*safe*) is CLEAR after a non-orderly shutdown. After the next NV update of *Clock,* safe is SET to indicate that *Clock* is not a repeat.

Clock is a volatile value that advances at the rate that *Time* advances. A non-volatile value (*NV Clock*) is updated periodically from *Clock*. *NV Clock* will always move forward as *Clock* advances. However, because of unexpected power loss, it is possible that the same value of *Clock* will be reported more than once. The mitigations for this are described in subsequent parts of this clause (36.3).

The accuracy of *Clock* is approximate. The causes of inaccuracy are

- the TPM's time reference may not be accurate, and
- the TPM must rely on external software to provide initial or periodic adjustments to *Clock* settings.

The interpretation of the time-origin (t=0) is out of the scope of this specification, although Coordinated Universal Time (UTC) is expected to be a common convention.

The value of *Clock* may be set forward by external software (TPM2_ClockSet()) to compensate for power interruptions or clock slew, but, except for changes in ownership (TPM2_Clear()), the TPM will not allow external software to set *Clock* backward.

The value of *Clock* may be advanced by TPM2_ClockSet() using either platform or owner authorization.

NOTE The value of *Clock* may not be advanced beyond FF FF 00 00 00 00 00 00_{16}. This restriction prevents any possibility of *Clock* rolling over during its lifetime and simplifies use of *Clock* in policies.

 Copyright © TCG 2006-2020

The TPM may be driven by an imprecise internal or external frequency source. To compensate, the TPM allows external software with a more reliable time source to make limited (+/-15%) adjustments to the rate of advancement of *Clock*.

36.3.2 *Clock* Implementation

The technology used for non-volatile storage may make the update rate for *NV Clock* an endurance issue. To mitigate this, the interval between updates of *NV Clock* from *Clock* are allowed to be as long as once per 2^{22} milliseconds.

NOTE If *NV Clock* is implemented in a technology that allows millisecond updates and has no endurance issues, then *Clock* and *NV Clock* may be the same.

Since *NV Clock* may be updated at a low rate, a power event may cause the value in *Clock* to appear to go backward. For example, assume that the update interval for *NV Clock* is the maximum allowed value (2^{22} milliseconds or approximately 70 minutes). Power may be removed from the TPM and *Time* just before an update of *NV Clock*. Then, when power is restored, *Clock* will be restored from *NV Clock* and *Clock* may have a value that is more than an hour older than the last reported value of *Clock*. This illustrates that the values of *Clock* reported by the TPM for the first hour of operation may have a lower value than values returned before the power outage.

The *Safe* flag in the TPMS_TIME_INFO structure is used to indicate if the reported value of *Clock* is guaranteed not to be a repeat of a previously reported value. The *Safe* flag is described in more detail in the following clause.

36.3.3 Orderly Shutdown of *Clock*

In order to reduce the amount of time that must pass before *Safe* is SET, the TPM supports an orderly shutdown. TPM2_Shutdown() is used to indicate to the TPM that software anticipates the loss of TPM power and that the appropriate state should be preserved. When the TPM receives TPM2_Shutdown(), it will copy all of the bits of *Clock* to *NV Clock.* After an orderly shutdown, the TPM will SET a non-volatile flag to indicate that an orderly shutdown has occurred.

NOTE 1 To allow the *NV Clock* to only have to record the upper bits of *Clock,* an alternate implementation is to keep *Clock* in memory that has a copy saved on an orderly shutdown and to restore *Clock* from that memory on the next power up.

After an orderly shutdown, *Clock* continues to count and *NV Clock* will be updated at the normal rate.

Any time a command is executed that uses the value of *Clock*, the flag indicating orderly shutdown will be CLEAR even if this command occurs subsequent to TPM2_Shutdown(). This flag may be SET when *NV Clock* is updated from *Clock*.

NOTE 2 It is possible for the TPM to perform multiple shutdowns before TPM power is actually lost.

If *Safe* is not SET when TPM2_Shutdown() is received, then *NV Clock* must not be set from *Clock* and *Safe* must not be SET on the subsequent startup.

It is permitted for the low-order 10 bits of *Clock* to come from *Time* and for *NV Clock* not to implement those bits. That is, *NV Clock* does not maintain resolution to better than 2^{10} milliseconds. If an implementation uses this option, then *Safe* will be CLEAR at least for the first 2^{10} milliseconds of TPM operation.

Clock remains safe as long as *Time* is powered. That is, if there is a non-Orderly shutdown and the TPM is powered down but *Time* is powered, then *Clock* will be updated the next time the TPM starts. Since time is not lost, *Clock* will not appear to go backwards and *Safe* can be SET. During the time that the

 Copyright © TCG 2006-2020

TPM is powered down it is not necessary for *Time* to advance, it simply needs not to be set to a lower time value.

36.3.4 *Clock* Initialization at TPM2_Startup()

On any TPM2_Startup() or _TPM_Init (vendor's choice), *Clock* is loaded from *NV Clock* and *Clock* begins incrementing at a one millisecond rate. *NV Clock* is then updated, no less frequently than the update interval. It is anticipated that the first update of *NV Clock* will occur when some number of low-order bits of the volatile *Clock* become zero, indicating the passage of the update interval. For example, assuming that the NV Clock update interval is 2^{12} (approximately every 4 seconds), the TPM may perform an update of *NV Clock* whenever the low-order 12 bits of volatile *Clock* are zero.

NOTE 1 If the TPM had an orderly shutdown, the low-order bits of the *NV Clock* will likely not be zero, so the first update of *NV Clock* after the _TPM_Init will occur in less than the normal update interval.

NOTE 2 If the TPM received TPM2_Shutdown() and a subsequent command that used *Clock*, then the NV value of *Clock* will likely be non-zero, but *Safe* will be CLEAR.

36.3.5 Setting *Clock*

The value in the volatile *Clock* may be set forward using TPM2_ClockSet(). The *newTime* parameter of TPM2_ClockSet() is required to have a greater value than the volatile *Clock*. So that policies that rely on *Clock* do not have to contend with the possibility of the value of *Clock* wrapping, *newTime* may not be greater than FF FF 00 00 00 00 00 00_{16}.

If TPM2_ClockSet() causes the volatile and non-volatile versions of *Clock* to differ by more than the implementation-dependent update interval, then *NV Clock* will be updated before TPM2_ClockSet() returns.

NOTE 1 It is not necessary that all the bits of *NV Clock* be updated. Only the bits of *NV Clock* that are updated in the normal update process need to be changed.

EXAMPLE Assume the update of *NV Clock* occurs every 2^{12} milliseconds (00 00 10 $00_{16)}$, that the low-order 32 bits of *NV Clock* are 00 00 00 00_{16} and *Clock* are 00 00 0F 00_{16}, and that a *newTime* advances *Clock* to 00 00 11 00_{16}. Since this makes the difference between *Clock* and *NV Clock* more than the update interval (2^{12}), *NV Clock* is updated to 00 00 11 00_{16}.

The expected management for *Clock* is for a coarse (large) update to be made after TPM2_Startup() in order to recover the time lost when the TPM was not powered. After that single large change, *Clock* is expected to be updated with relatively small values to keep it synchronized with real time. If software manages *Clock* in this manner, TPM2_ClockSet() will not have to be throttled in order to avoid NV wear-out.

NOTE 2 System software may purposely cause the rate of *Clock* advance to be slower than real time and just make minor adjustments when an attestation of some sort is required. If managed in this way, TPM2_ClockSet() may be executed many times between update intervals. Because update of the NV portion of *Clock* is not allowed unless the difference between the two versions is at least as large as the update interval, TPM2_ClockSet() will not need throttling to avoid wear-out.

NOTE 3 The specification could have been written so that TPM2_ClockSet() would never invoke NV throttling. That is, the value for *newTime* could have been set such that the rate of *NV Clock* update would be at an acceptable rate or TPM2_ClockSet() would fail. This logic is complex, and under normal circumstances, redundant. As a consequence, the specification does not place restrictions on the values of *newTime* other than those listed above. The fact that TPM2_ClockSet() requires Owner Authorization or Platform Authorization should provide some level of protection against an attacker using TPM2_ClockSet() for a wear-out attack on the TPM. TPMs may implement wear-protection if extraordinary rates of update are observed.

36.3.6 *Clock* Periodicity

The TPM clock may be driven by an internal or external frequency source or be derived from a time source supplied by its operating environment. TPM profiles shall specify the time source to be used and the required accuracy.

External software may make limited adjustments to the rate of advance of *Clock* to provide a better approximation to real time.

This specification requires that the nominal rate of advance of *Clock* when powered is within 15% of the rate of UTC. If the external clock is not reliable, the TPM must provide its own clock with the necessary accuracy. External software may indicate that *Clock* is not advancing at the rate of UTC and that the rate needs to be increased or decreased. The command to adjust the clock rate is TPM2_ClockRateAdjust(). The *newRate* parameter of this command allows fine or coarse upward or downward adjustments to the current counting rate. This specification does not define coarse or fine adjustment percentages, and software that manages the TPM must infer this from observed behavior.

The range of adjustment of the rate is dependent on the design of the TPM. It is required that the variation in the rate be large enough that it will allow software to adjust the rate of *Clock* advance to be the same as UTC. The TPM should not allow rate adjustments that are larger than the design tolerance of the TPM.

EXAMPLE 1 A TPM is designed to have a nominal internal oscillator frequency of 10 MHz with a tolerance of +/-15% and a presettable counter that is used to count the oscillator clocks and generate an output every second that is used to advance *Clock*. To cover the tolerance of the oscillator, the preset for the counter would have to be between 8,500,000 and 11,500,000.

EXAMPLE 2 A TPM is designed as above but with the additional ability to accept an outside frequency reference as long as that reference is at least +/-15%. If the external source is more accurate than +/-15%, then the TPM may still allow an adjustment over the 8,500,000 to 11,500,000 range.

NOTE 1 In the worst case, an attacker who knows either the Platform Authorization or Owner Authorization value may be able to make the TPM run 32.5% (1.15^2) fast or slow. However, an attacker who knows the Platform Authorization or Owner Authorization could also set *Clock* arbitrarily far into the future.

An error is returned if external software tries to adjust the clock rate outside specified bounds.

The TPM may store adjustments to the nominal clock rate in volatile memory. If it does, then adjustment should only be stored on an orderly shutdown and not during the actions of TPM2_ClockRateAdjust(). That is, the adjustment value should be in volatile memory and only saved to nonvolatile memory on an orderly shutdown.

NOTE 2 This constraint on TPM2_ClockRateAdjust() is so that software may make changes to the rate at arbitrarily high rates without causing an NV event that might require throttling.

36.4 resetCount

The *resetCount* is a non-volatile, 32-bit counter that is incremented on a successful TPM Reset. It may be read using TPM2_ReadClock() and be used in an authorization policy (TPM2_PolicyCounterTimer()). Additionally, the contents of the *resetCount* are included in the attestation data for any of the attestation commands.

NOTE 1 Depending on the hierarchy of the signing key, the value of *resetCount* may be obfuscated so that a verifier can tell that the counter has changed but cannot know the absolute value of the counter.

The purposes of *resetCount* are to indicate when the static trust state of the platform may have changed and to indicate a possible discontinuity in *Clock*.

 Copyright © TCG 2006-2020

EXAMPLE Without the *resetCount*, the sequence - (1) attest to trusted values (2) transition to an untrusted state (3) perform a transaction (4) TPM Reset (5) attest to trusted value - would hide the fact that the transaction may have occurred during an untrusted state.

NOTE 2 Since the volatile *Clock* is reloaded from the *NV Clock* on each _TPM_Init, the volatile *Clock* will lose some time in nearly all circumstances.

resetCount is incremented whenever the TPM starts up and all previous state is lost (i.e., on a TPM Reset). *resetCount* is set to zero in TPM2_Clear().

36.5 restartCount

In addition to TPM Reset, other events may cause a discontinuity in TPM-recorded time or in the Root of Trust for Reporting (RTR). A suspend-resume cycle will cause a time discontinuity. _TPM_Hash_Start can cause an RTR discontinuity in the dynamic Root of Trust for Measurement (D-RTM) PCR. The *restartCount* is used to provide an indication of these discontinuities.

The *restartCount* is a non-volatile, 32-bit counter that increments when the TPM executes TPM Resume, TPM Restart, or _TPM_Hash_Start. Since *resetCount* increments on each TPM Reset, the combination of *resetCount* and *restartCount* accounts for the cases when a discontinuity may occur, allowing TPM *Time* to fall behind real time.

NOTE When software sets *Clock* forward, that is a positive time discontinuity under control of software. The negative discontinuities of *Clock* are due to hardware actions that may be outside of the control of software.

The combination of *resetCount* and *restartCount* also accounts for the discontinuities of the RTR. A change in *resetCount* indicates a discontinuity in the static RTR, and a change in *restartCount* indicates a change in the dynamic RTR.

restartCount is reset to 0 on TPM Reset – when *resetCount* is incremented. This does not cause a loss of information about the dynamic RTR because a change to *resetCount* also implies a change to the dynamic RTR.

36.6 Note on the Accuracy and Reliability of *Clock*

Clock is designed to allow a managed environment, such as enterprise, to maintain a small deviation between *Clock* and real time. If the platform is not managed, if the platform falls into the hands of an adversary, or if the platform is controlled by malware, then accuracy of *Clock* is diminished. This note addresses considerations that influence the applicability of *Clock* for time-stamping and for time-limited objects.

This analysis assumes that the TPM is not physically attacked, but that adversaries may manipulate external software and local clocks like the CMOS clock on PC platforms.

It is assumed that, under normal operation, external software adjusts *Clock* at platform startup and subsequently makes occasional additional rate and forwarding adjustments to ensure that *Clock* remains within acceptable tolerances. Enterprise management servers or web services may occasionally request time-stamped nonces to check that *Clock* meets network policy.

If *Clock* is used to time-stamp event log entries, then server software should ensure that *Clock* is accurate (as described above), and client software may occasionally record TPM *Time* values counter-signed by external authoritative time-stamping services to provide fiduciary time markers. These services may include the *Clock* and *Time* values as well as the initialization counters (*resetCount* and *restartCount*). The minimal security guarantees provided by the TPM in this case are

 Copyright © TCG 2006-2020

- proper ordering of events logged at times greater than 1 millisecond apart (apart from when associated with discontinuities in the *resetCount* and *restartCount*), and
- that time stamps can never be forged to indicate a time in the past. If the value of *Clock* could be "stale," *Safe* will indicate as much. If *Clock* has occasionally been reported to other authorities or has been counter-signed, then the accuracy of the other time stamps can be interpolated more accurately.

If *Clock* is used to lifetime-limit objects, then when the platform is properly managed, objects will become inaccessible with temporal accuracy related to the precision of clock management and the update interval of *NV Clock*. If the lifetime has the granularity of *NV Clock* update, then once it becomes inaccessible, it cannot be recovered because, at that granularity, *Clock* will not move backward. If the granularity of the lifetime needs to be shorter than the update interval of *Clock*, then the *Safe* flag can be checked to see if the value of *Clock* may be "stale" or not.

If the platform falls into adversarial hands, the attacker will never be able to recover already revoked objects. However, for objects with lifetimes in the future, an adversary may effectively stop the passage of time so that objects never expire.

EXAMPLE To make TPM *Time* "stop," the platform should only be turned on briefly to access the time-limited object and then turned off in a way that prevents an orderly shutdown of the TPM. If the TPM is left on for less than the update interval and the platform does not have an orderly shutdown, *Clock* will continue to repeat values within the range of an update interval. In a managed environment, a platform with a *Clock* that has a value that is substantially different from real time will likely be denied further network services. For a system in an unmanaged environment, a more complex policy using *resetCount* and *Time* may be used to limit access to objects even if time does not advance (for example, the policy may allow access for 20 minutes or 2 reboots).

When the owner of the platform changes (new SPS generated) *Clock* is reset to zero. Using *Clock* to do time stamping with a non-duplicable key does not constitute a vulnerability because the signing key also becomes inaccessible when the owner changes, so no new events can be created. If the time-stamping key is duplicable, then a more detailed security analysis is needed — for instance, examination of the Qualified Name in the signing structure.

If *Clock* is used in other policy settings, similar considerations apply. If an object is destroyed when the owner is changed, then *Clock* reset is benign. However, if an object survives an owner change (such as, an NV Index created by the platform), then use of *Clock* in its access policy may not be appropriate.

36.7 Privacy Aspects of Clock

The attestation structures return several values that, when taken together, may be sufficiently unique to identity a specific platform. For example, the difference between *Clock* and *Time* is, during the interval of a boot, likely to be somewhat unique for a platform. When combined with *resetCount* and *restartCount*, the values can become very indicative of a specific platform. If these values allow signatures from two keys to be correlated, then those keys remain correlated as long as they are in use. The TPM uses authorizations and obfuscation values to prevent this type of unwanted correlation.

All attestations contain a TPMS_CLOCK_INFO structure. That structure contains *Clock*, *resetCount*, *restartCount*, and *Safe*. The attestation structure also contains a 64-bit value that is indicative of the firmware version number. When these values are going to be signed by a key that is not in the Platform or Endorsement hierarchy, *resetCount*, *restartCount*, and firmware version number have a key-specific value added to them before they are put into the attestation structure. The addition allows the determination of change in values but prevents disclosure of the exact value.

Each Attestation Key has a different 128-bit obfuscation value that is constant for the lifetime of the key. It is computed by:

37 NV Memory

37.1 Introduction

Each TPM is required to have some non-volatile memory. This memory is used to retain values across power events. The NV memory is used to hold:

- NV Index values,
- objects made persistent by TPM2_EvictControl,
- state saved by TPM2_Shutdown(), and
- Persistent NV data.

37.2 NV Indices

37.2.1 Definition

An NV Index is space that is defined by a user of the TPM. The Index is identified by a unique handle value. An NV Index handle has an MSO of TPM_HT_NV_INDEX.

The NV Index structure has:

- An identifying handle – this handle is assigned by the caller when the Index is defined and is used to reference the Index. The handle associated with an Index has an MSO of TPM_HT_NV_INDEX.
- A *nameAlg* – this parameter indicates the hash algorithm used in the computation of the Name of the Index (see clause 16).
- An authorization policy – this parameter is optional and is the digest of the policy for the NV Index. For the policy to apply to an operation, the corresponding TPMA_NV_POLICY_READ, TPMA_NV_POLICY_WRITE, or TPMA_NV_POLICY_DELETE attribute needs to be SET. Different policies for read, write, and delete can be achieved using policy OR terms and TPM2_PolicyCommandCode().
- A set of NV Index attributes – this parameter determines the nature of the Index and who may manipulate or read the Index.
- An authorization value that is no larger than the size of the digest produced by the *nameAlg* of the NV Index.
- A value indicating the size of the Index data – this parameter indicates the number of octets that are required to hold the NV data. For some Index types, the size is fixed.
- The NV Index data that may be modified according to the type of the NV Index.

All the parts of the NV Index structure, except for the *authValue* and Index data, constitute the public portion of the Index. They are hashed using the *nameAlg* to produce the Name of the Index.

The public area of the Index may be read using TPM2_NV_ReadPublic().

NOTE TPM2_NV_ReadPublic() also returns the Name of the NV Index.

An NV Index can be designated as a hybrid Index. A hybrid Index is intended for applications where frequent updates are expected. High frequency updates are generally not compatible with the technology currently used for nonvolatile storage on a TPM. A hybrid Index maintains a volatile (RAM) and a non-volatile copy of its Index data. A write to an ordinary Index is immediately written to NV memory but a

 Copyright © TCG 2006-2020

write to a hybrid Index may only update the copy of the Index data in RAM. The non-volatile copy of a hybrid NV Index is updated on TPM2_Shutdown().

If an NV Index has TPMA_NV_ORDERY SET, then it is a hybrid Index.

NOTE 1 The user of a hybrid NV Index must understand that data may be lost if the TPM does not shut down in an orderly fashion so that the volatile data can be written to NV memory.

Whether or not NV Index is a hybrid, when an NV Index is defined (TPM2_NV_DefineSpace()), the persistent values of the NV Index are written to NV if the command completes successfully.

Any NV Index type can be defined as a hybrid. The conditions under which the write to NV memory occur vary and are described below.

NOTE 2 An implementation is not required to support an arbitrary number of hybrid indices and is not required to support any ordinary hybrid Index with a size of more than eight octets.

37.2.2 NV Index Allocation

An NV Index is allocated with TPM2_NV_DefineSpace(). Either Platform Authorization or Owner Authorization is required in order to allocate an Index. The caller indicates the NV Index to assign to the NV location, the access controls for the Index, and the type and or size of the data buffer that should be reserved for writing. While the allocation process does write the meta-data for the Index to NV, it does not write to the data area of the Index data and a read of the NV location before it is written will return an error (TPM_RC_NV_UNINITIALIZED).

When an NV Index is defined (TPM2_NV_DefineSpace), its TPMA_NV_WRITTEN attribute will be CLEAR. Until the Index is written by a party that can satisfy the write policy, the Index is defined but has no data, and TPM2_PolicyNV() and TPM2_NV_Read() will fail.

TPMA_NV_WRITTEN is SET when an authorized party first writes the Index. This permits a relying party to know that the value in the Index was written by an authorized party. It is not simply a default value that was present when the Index was defined (or deleted and redefined to attempt a roll back.)

A replying party can read the Index attributes and policy, which are public, to determine the authorized party.

NOTE The meta-data of an NV Index is the data relating to the NV Index description (Index number, policy, attributes, data size, and *authValue*) along with any additional information that the TPM needs to manage the NV Index memory.

Different types of NV Index may be supported.

- **Ordinary** – an Index with an NV Index type of TPM_NT_ORDINARY contains data that is opaque to the TPM that is modified using TPM2_NV_Write().
- **Counter** – an Index with an NV Index type of TPM_NT_COUNTER contains a 64-bit counter that is modified using TPM2_NV_Increment().
- **Bit field** – an Index with an NV Index type of TPM_NT_BITS contains 64 bits that are initialized to 0 and are modified using TPM2_NV_SetBits().
- **Extend** – an Index with an NV Index type of TPM_NT_EXTEND contains a value that has behavior similar to a PCR and is modified using TPM2_NV_Extend().
- **PIN Fail** - an Index with an NV Index type of TPM_NT_PIN_FAIL that contains a TPMS_NV_PIN_COUNTER_PARAMETERS structure that is modified using TPM2_NV_Write() or by using the *authValue* of the Index. *pinCount* is reset when an authorization attempt using *authValue* succeeds. *pinCount* is incremented after an authorization attempt using *authValue* fails. *pinCount*

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

cannot increment beyond *pinLimit* because *authValue* authorization is locked out if *pinCount* >= *pinLimit*. A Pin Fail Index can be modified with TPM2_NV_Write.

- **PIN Pass** - an Index with an NV Index type of TPM_NT_PIN_PASS that contains a TPMS_NV_PIN_COUNTER_PARAMETERS structure that is modified using TPM2_NV_Write() or by using the *authValue* of the Index. *pinCount* is incremented after an authorization attempt using *authValue* succeeds. *pinCount* cannot increment beyond *pinLimit* because *authValue* authorization is locked out if *pinCount* >= *pinLimit*. A Pin Pass Index can be modified with TPM2_NV_Write.

TPM2_NV_DefineSpace() can fail if an Index with the requested handle already exists or if there is insufficient NV memory for the allocation. Creation of a hybrid Index will fail if there is insufficient RAM available for the allocation. The command will fail if an Index type is not supported.

EXAMPLE If the TPM does not implement TPM2_NV_Extend(), then the TPM will not allow creation of an NV Index that has the TPMA_NV_EXTEND attribute.

If the Index to be created has its TPMA_NV_POLICY_DELETE attribute SET, then platform authorization is required for allocation. This attribute is only allowed to be selected if TPM2_NV_UndefineSpaceSpecial() is implemented on the TPM.

NOTE This attribute indicates that a policy is required to delete the Index. It permits creation of an Index that can never be deleted, for example, by specifying an Empty Policy. Requiring platform authorization protects against the current TPM owner creating such an Index.

37.2.3 NV Index Deletion

An NV Index can be removed using either TPM2_NV_UndefineSpace() or TPM2_NV_UndefineSpaceSpecial().

If the TPMA_NV_POLICY_DELETE attribute is SET, then the Index can only be deleted if ADMIN role authorization is provided. ADMIN role authorization is provided by a policy session with the *commandCode* of the policy set to TPM2_NV_UndefineSpaceSpecial().

TPM2_NV_UndefineSpace is used to delete other Indices from the NV. The authorization given for deleting the Index is required to be the same as the authorization given to allocate the Index.

TPM2_Clear() will remove any NV Index that used Owner Authorization to define the Index. TPM2_Clear() uses either TPM_RH_LOCKOUT or TPM_RH_PLATFORM.

TPM2_ChangePPS() does not cause any NV Index to be removed.

NOTE To comply with FIPS-140, the data contents and authorization value must be zeroized when the NV Index is deleted.

37.2.4 High-Endurance (Hybrid) Indices

37.2.4.1 Description

Some applications need the ability to make frequent updates to non-volatile values such as monotonic counters. A high update rate is generally not compatible with the technology currently used for non-volatile storage on a TPM. To allow the TPM to support high-update rates while protecting the endurance of the NV memory, a hybrid Index type is defined.

When an NV Index is defined with the TPMA_NV_ORDERLY attribute SET, the TPM will allocate the required NV memory as well as space in TPM RAM for the data value. During normal operation, updates to the Index will modify the RAM copy of the Index data with updates to the NV on Shutdown() or

whenever the RAM copy of a counter is divisible by a set modulus. In some cases, the data write may never occur.

NOTE The value of the modulus is implementation specific and can be accessed using TPM2_GetCapability(*capability* == TPM_CAP_TPM_PROPERTY, *property* == TPM_PT_ORDERLY_COUNT). The returned value is the modulus – 1. This value is referred to as MAX_ORDERLY_COUNT.

If the TPMA_NV_ORDERLY attribute of an Index is SET, the TPM will perform special processing on the Index at TPM2_Startup(). The processing is dependent on the type of the Index.

37.2.4.2 Hybrid Indices Other than Counter Indices

For hybrid Indices that are not Counters, the NV Index data in volatile memory is copied to non-volatile memory on a Shutdown(STATE), The data need not be copied to non-volatile memory on Shutdown(CLEAR).

a) On TPM Resume, the non-volatile copy of the Index data is copied into the volatile version of the NV Index data.
b) On TPM Reset, the TPMA_NV_WRITTEN attribute will be initialized to CLEAR. On a subsequent update of the Index, it will be initialized before it is updated.
c) On TPM Restart, if TPMA_NV_CLEAR_STCLEAR is SET, the NV Index is initialized as in b) above. If TPMA_NV_CLEAR_STCLEAR is CLEAR, then the NV Index is initialized as in a) above.

NOTE TPMA_NV_CLEAR_STCLEAR may not be SET if the NV Index type is TPMA_NV_COUNTER. Counters are either restored (on an orderly startup) or set to a higher value (on a non-orderly startup).

37.2.4.3 Counter Hybrid Indices

The hybrid counter Index is designed so that it will be monotonically increasing and not miss an increment command regardless of the type of shutdown or startup.

For a Counter NV Index with the TPMA_NV_ORDERLY attribute, Index data in non-volatile memory is written to NV on any Shutdown().

NOTE 1 For a Counter (or any other Index) that has TPMA_NV_ORDERLY CLEAR, non-volatile memory is written on any update of the NV Index.

On any orderly startup of the TPM (TPM2_Startup() following an orderly shutdown), the NV value of a hybrid counter Index will be copied to the RAM version. The count will be able to continue without any discontinuity.

On a non-orderly startup, the value of the counter in NV is adjusted before it is copied to RAM. A counter is adjusted by logical OR of the value of MAX_ORDERLY_COUNT to the NV value. This sets the RAM version of the counter to the maximum value it could have had before being updated due to the modulus test. This ensures that the RAM counter value is no less than any previously used counter value.

EXAMPLE Assume that MAX_ORDERLY_COUNT contains 0F FF_{16} and that the TPM lost power without an orderly shutdown. On a startup, if an orderly counter is found to have a value of 00 00 00 00 00 01 73 $A1_{16}$, then the RAM version is updated to 00 00 00 00 00 01 7F FF_{16}.

NOTE 2 When the RAM version of the counter is set this way, it is not necessary to immediately update the counter to NV. If the counter is incremented, then it will be automatically saved to NV when the low bits become zero.

 Copyright © TCG 2006-2020

NOTE 3 If the RAM counter were initialized so that the low bits were zero and a subsequent un-orderly shutdown occurred, the counter would have to be advanced again, whether it had been incremented or not. By setting the counter to the maximum value before NV update, there is no need to advance the count on a subsequent unorderly shutdown unless the counter was used.

37.2.5 Reading an NV Index

Read access to an NV Index is provided with TPM2_NV_Read(), TPM2_NV_Certify(), and TPM2_PolicyNV(). For all of these commands, read authorization is required. The attributes of the Index determine what authorizations are allowed. TPMA_NV_PPREAD allows the Index to be read using Platform Authorization*;* TPMA_NV_OWNERREAD allows the Index to be read using Owner Authorization; TPMA_NV_AUTHREAD allows the Index to be read using the *authValue* of the Index; and TPMA_NV_POLICYREAD allows the Index to be read if the *authPolicy* of the Index is satisfied.

At least one of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD or TPMA_NV_POLICYREAD needs to be SET or the TPM will not allocate the Index.

An access control (TPMA_NV_READ_STCLEAR) allows reading of the Index to be temporarily blocked. When this attribute is SET, TPM2_NV_ReadLock() may be used to temporarily disable read access to the Index. When the Index has been locked for read, the TPMA_NV_READLOCKED attribute of the Index will be SET. TPMA_NV_READLOCKED will be CLEAR on the next TPM Reset or TPM Restart. If the TPMA_NV_READLOCKED attribute is SET when the Index is read, the TPM returns TPM_RC_NV_LOCKED.

The *authPolicy* of the NV Index may be constructed such that it only applies for reading or for writing. It may be constructed to allow general reading and limited writing or general writing and limited reading. If reading or writing of the Index is to be restricted based on PCR values, then read authorization needs to use *authPolicy*.

37.2.6 Updating an Index

37.2.6.1 Introduction

The command used to update an Index is determined by the NV Index type. TPM2_NV_Write() is used to modify an Ordinary Index or a PIN Index, TPM2_NV_Increment() is used to modify a Counter Index, TPM2_NV_SetBits() is used to modify a Bit Field Index, and TPM2_NV_Extend() is used to modify an Extend Index. For all of these commands, write authorization is required.

The attributes of the Index determine what authorizations are allowed. TPMA_NV_PPWRITE allows the Index to be modified using Platform Authorization*;* TPMA_NV_OWNERWRITE allows the Index to be modified using Owner Authorization; TPMA_NV_AUTHWRITE allows the Index to be modified using the *authValue* of the Index; and TPMA_NV_POLICYWRITE allows the Index to be modified if the *authPolicy* of the Index is satisfied.

At least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE or TPMA_NV_POLICYWRITE needs to be SET or the TPM will not allocate the Index. For a PIN Index, TPMA_NV_AUTHWRITE may not be SET and at least one of the other three write methods is required to be selected.

NOTE 1 A method other than TPMA_NV_AUTHWRITE is required for a PIN Index because the *authValue* of a PIN Index is not accessible until the Index is written.

If the access control attribute TPMA_NV_WRITEDEFINE is SET, TPM2_NV_WriteLock() or TPM2_NV_GlobalWriteLock() may be used to permanently disable modify access to the Index. When the Index has been locked for modify, the TPMA_NV_WRITELOCKED attribute of the Index will be SET. This attribute will remain SET until the Index is deleted (TPM2_NV_UndefineSpace()).

If TPMA_NV_WRITEDEFINE is CLEAR, the TPMA_NV_WRITELOCKED attribute can be SET using TPM2_NV_WriteLock() if TPMA_NV_WRITE_STCLEAR is SET or TPM2_NV_GlobalWriteLock() if TPMA_NV_GLOBALLOCK is SET. In this case, TPMA_NV_WRITELOCKED will be CLEAR on the next TPM Reset or TPM Restart.

NOTE If TPMA_NV_WRITELOCKED is SET, but TPMA_NV_WRITTEN is CLEAR, then TPMA_NV_WRITELOCKED is CLEAR by TPM Reset or TPM Restart. This is true even if the TPMA_NV_WRITEDEFINE attribute is set. It prevents an NV Index from being defined that can never be written and permits a use case where an Index is defined, but the user wants to prohibit writes until after a reboot.

If the TPMA_NV_WRITELOCKED attribute is SET when an attempt is made to modify the Index, the TPM returns TPM_RC_NV_LOCKED.

For a PIN Fail Index, the TPM will return TPM_RC_NC_ATTRIBUTES if TPMA_NV_NO_DA is CLEAR.

37.2.6.2 NV Ordinary Index Update

TPM2_NV_Write() is used to modify the contents of an ordinary Index. The modification may be to the entire Index or, if the Index attributes allow (TPMA_NV_WRITE_ALL CLEAR), the size of the data to write can be as small as zero octets.

When a partial write is allowed, the *offset* parameter of TPM2_NV_Write() may be non-zero or the *size* of the data parameter may be less than the *size* of the Index. The TPM checks the TPMA_NV_WRITTEN attribute. If it is CLEAR, then the TPM will initialize the remainder of the Index to either all zero or all one. Alternatively, the TPM can initialize the entire Index at the time the Index is defined.

If the sum of the size of the *data* parameter and the *offset* parameter in TPM2_NV_Write() is greater than the size of the Index, then the TPM will not perform the write and will return an error.

On any TPM2_NV_Write() (including a size of zero), if the modification is successful, then the TPMA_NV_WRITTEN attribute of the Index will be SET. Any octets not initialized by the first write will have a value of all zero or all one.

EXAMPLE If the Index is defined to contain 2 octets, and the first write of the Index is a single octet of 55_{16}, to offset 0, then the next read of the full Index will return 55 00_{16}.

If the Ordinary Index has the TPMA_NV_ORDERLY attribute, then only the RAM version of the Index is written. The data is preserved on a Shutdown(STATE).

37.2.6.3 NV Counter Index

When an Index has the TPMA_NV_COUNTER attribute, it behaves as a monotonic counter and may only be modified using TPM2_NV_Increment().

When an NV counter is created, it has no value and the TPMA_NV_WRITTEN attribute will be CLEAR.

On each TPM2_NV_Increment() the TPM checks the TPMA_NV_WRITTEN attribute of the Index. If it is CLEAR, then the TPM will initialize the 8-octet counter value such that the first increment will set a value that is greater than any value that a counter Index with the same Name has had over the lifetime of the TPM. The TPMA_NV_WRITTEN attribute will be SET.

NOTE 1 This check ensures that an Index cannot be deleted and another Index with the same Name defined with a lower value.

NOTE 2 The reference implementation implements this by tracking and using the largest count of any deleted NV Counter. An alternative implementation could track the largest count of any NV Counter, deleted or currently defined.

 Copyright © TCG 2006-2020

After checking TPMA_NV_WRITTEN and performing any required initialization operations, the TPM will increment the Counter.

NOTE 3 The TPM will need to maintain a largest-count value. It is not necessary to update this value except when a NV Index is deleted. If the NV Index being deleted has the largest value held by an NV Index, then this value would be copied to the largest-count value. The value of an NV Counter Index after the first increment is larger than the largest-count value.

NOTE 4 Since no counter can ever repeat a previous value ever contained in any NV Counter Index, a counter with a particular Name cannot be rolled back by deleting it and redefining it.

If the TPMA_NV_ORDERLY attribute is CLEAR, the increment will occur on the NV version of the counter (no RAM version exists). If the TPMA_NV_ORDERLY attribute is SET, the increment will occur on the RAM version of the counter, and if this causes a rollover, the NV version of the counter is updated. However, if TPMA_NV_WRITTEN is CLEAR, the NV version of the counter is also written. Once SET, TPMA_NV_WRITTEN of a counter is never CLEAR.

An Index may be defined with the TPMA_NV_ORDERLY attribute to indicate that the Index is expected to be modified at a high frequency and that the data is only required to persist when the TPM goes through an orderly shutdown process. For a counter, it also means that it will be written to NV when the counter has reached some threshold value. The threshold value for counters (MAX_ORDERLY_COUNT) is implementation dependent and can be read using TPM2_GetCapability(capability = TPM_CAP_PT, property = TPM_PT_ORDERLY_COUNT). This property has one of 32 values that can be expressed as (2^N-1) where N is between 1 and 32.

EXAMPLE If MAX_ORDERLY_COUNT is 00 00 0F FF_{16}, then whenever the RAM version of a counter is incrementing, causing the low-order 12 bits to be zero, the NV version of the counter is updated.

The meaning of this threshold value is that when the counter is incremented such that the counter value ANDed with MAX_ORDERLY_COUNT is zero, then the NV version of the counter will be updated.

NOTE 5 Another way to express this is to simply say that the NV version of the counter will be updated when the low order bits of the counter "roll-over".

The TPM is required to ensure that, when an NV Counter is read, its value is not less than a previously reported value of the counter. That is, it may not go backward. If the shutdown was orderly, then, regardless of the type of the NV Counter, the NV value of a counter will not be less than the last reported value. If the shutdown was not orderly and the NV Counter has the TPMA_NV_ORDERLY attribute, then a value of the Counter may have been read from the RAM version of the counter but the NV version may not have been updated. To handle this case, if the TPMA_NV_ORDERLY attribute of an NV Counter is SET, and the TPM shutdown was not orderly, then, at TPM2_Startup() the TPM will OR the value of MAX_ORDERLY_COUNT to the contents of the non-volatile counter and set that as the current count in the RAM version of the counter.

NOTE 6 The TPM must prevent a rollback attack caused by a counter being deleted and then being recreated with a lower value. To do this, the TPM may keep track of the value of the highest count of a deleted counter using a phantom counter. When a counter is deleted, the current value of the counter is compared to the current phantom counter and other counters. If the value is larger than the phantom counter and other counters, the phantom counter is updated. When a new NV counter is created, it starts with the highest value of all the counters, including the phantom counter.

For a Counter with the TPMA_NV_ORDERLY attribute SET, the NV copy of the data will be updated whenever a specified number of low order bits of the RAM copy become all zeros. That number of low order bits is TPM implementation-dependent. The setting for a TPM may be found using TPM2_GetCapability(TPM_CAP_TPM_PROPERTIES, TPM_PT_ORDERLY_COUNT). That capability is MAX_ORDERLY_COUNT.

The TPMA_NV_CLEAR_STCLEAR attribute has no effect on an NV Counter Index and it may be SET or CLEAR in the template.

 Copyright © TCG 2006-2020

37.2.6.4 NV Bit Field Index

When an Index has the TPMA_NV_BITS attribute it may only be modified by TPM2_NV_SetBits().

When an NV Bit Field Index is created, it has no value and the TPMA_NV_WRITTEN attribute will be CLEAR.

On each TPM2_NV_SetBits(), the TPM will check the TPMA_NV_WRITTEN attribute of the Index. If it is CLEAR, the TPM will set the 64 bits of the Index to zero. The TPM will then SET the TPMA_NV_WRITTEN attribute for the Index.

After checking TPMA_NV_WRITTEN and doing any necessary initialization, the TPM will OR the *bits* parameter to the Index.

If the TPMA_NV_ORDERLY attribute is not SET, the NV value of the Index is written with the modified value. If no bits were SET in the *bits*, the NV Index data will only be updated if TPMA_NV_WRITTEN was CLEAR when the command execution was started.

If TPMA_NV_ORDERLY is SET, the RAM version of the Bit Field data is updated but it is not written to NV. The data is only preserved to NV on a Shutdown(STATE), and on TPM Reset, the TPMA_NV_WRITTEN attribute of the Index will be CLEAR.

37.2.6.5 NV Extend Index

When an Index has the TPMA_NV_EXTEND attribute, it may only be modified by TPM2_NV_Extend().

When an NV Extend Index is created, it has no value and the TPMA_NV_WRITTEN attribute will be CLEAR.

On each TPM2_NV_Extend(), the TPM will check the TPMA_NV_WRITTEN attribute of the Index. If it is CLEAR, the TPM will initialize the Index to a Zero Digest that is the size of the digest produced by the *nameAlg* of the Index. The TPM will then SET the TPMA_NV_WRITTEN attribute for the Index.

After checking TPMA_NV_WRITTEN and doing any necessary initialization, the TPM will extend the Index using:

$$nvIndex{\rightarrow}data_{new} \coloneqq \mathbf{H}_{nameAlg}\left(nvIndex{\rightarrow}data_{old} \,||\, data.buffer\right) \tag{57}$$

where

$\mathbf{H}_{nameAlg}$	the hash algorithm indicated in *nvIndex→nameAlg*
$nvIndex{\rightarrow}data$	the value of the data field in the Index
$data.buffer$	the data buffer of the command parameter

If the TPMA_NV_ORDERLY attribute is not SET, the NV value of the Index is written with the modified value.

If TPMA_NV_ORDERLY is SET, the RAM version of the Index is updated but it is not written to NV. The data is only preserved on a Shutdown(STATE), and on TPM Reset, the TPMA_NV_WRITTEN attribute of the Index will be CLEAR..

 Copyright © TCG 2006-2020

37.2.6.6 NV PIN Index

TPM2_NV_Write() is used to modify the contents of a PIN Index. The modification may be to the entire Index or, if the Index attributes allow (TPMA_NV_WRITE_ALL CLEAR), the size of the data to write can be as small as zero octets.

When a partial write is allowed, the *offset* parameter of TPM2_NV_Write() may be non-zero or the *size* of the data parameter may be less than the *size* of the Index. The TPM checks the TPMA_NV_WRITTEN attribute. If it is CLEAR, then the TPM will initialize the remainder of the Index to either all zero or all one. Alternatively, the TPM can initialize the entire Index at the time the Index is defined.

If the sum of the size of the *data* parameter and the *offset* parameter in TPM2_NV_Write() is greater than the size of the Index, then the TPM will not perform the write and will return an error.

On any TPM2_NV_Write() (including a size of zero), if the modification is successful, then the TPMA_NV_WRITTEN attribute of the Index will be SET. Any octets not initialized by the first write will have a value of zero.

EXAMPLE If the Index is defined to contain 2 octets, and the first write of the Index is a single octet of 55_{16}, to offset 0, then the next read of the full Index will return 55 00_{16}.

If the Index has the TPMA_NV_ORDERLY attribute SET, then only the RAM version of the Index is written. The data is only preserved to NV on a Shutdown(STATE), and on TPM Reset, the TPMA_NV_WRITTEN attribute of the Index will be CLEAR.

If the *authValue* of an PIN Index is used for authorization, then the authorization will fail if the *pinCount* field of the Index is not less than the *pinLimit* field or if the TPMA_NV_WRITTEN attribute of the Index is CLEAR.

When the *authValue* of a PIN Index is used for authorization and the authorization succeeds, the *pinCount* field is set to zero if the Index is PIN Fail and incremented if the Index is PIN Pass. If the authorization fails, *pinCount* is incremented for a PIN Fail Index and left unchanged for a PIN Pass Index.

37.2.7 NV Index in a Policy

TPM2_PolicyNV() may be used to include the contents of an NV Index in a policy command. TPM2_PolicyNV() allows various comparisons of the value of the NV data with a reference value.

TPM2_PolicyNV() is an immediate assertion (see 19.7.7.2). If the comparison succeeds, the TPM will update the *policyDigest* with the comparison values and the access controls on the referenced Index, including the *authPolicy*. Inclusion of the update policy of the Index provides a means of identifying the update properties of the Index. To make effective use of this command, writing of the Index should be dependent on *authPolicy.* If the policy must be met in order to write the Index, then it is possible to ensure that only the correct entity may recreate the Index. If other write authorizations are allowed, then it is not possible to know if the Index was written by a known entity.

If an NV Index is used in TPM2_PolicyNV() after it is defined but before it is first written, then the TPM will return an error.

The nominal use of a PIN Index is to reference the Index in an entity's policy in TPM2_PolicySecret(). The TPM2_PolicySecret() will succeed if *pinCount* is less than *pinLimit* and the caller is able to provide the *authValue* of the Index in the authorization. If the rest of the policy is satisfied, access to the PIN-protected entity will be allowed.

NOTE 1 A PIN Fail Index provides a form of individual Dictionary Attack defense that is not affected by the TPM's global Dictionary Attack mechanism. In particular, it can be used to allow the TPM to emulate the behavior of a smart card.

NOTE 2 A PIN Pass Index allows count-limited use of a TPM object. An example use would be to only allow access to a decryption key for protected content.

37.2.8 PIN Index Considerations

37.2.8.1 Restricting the number of uses of an object with PIN Pass

It is possible to limit the number of *authValue* (PIN) authorizations of a particular key or entity.

A key or object has a limited number of authorizations when its policy has a TPM2_PolicySecret assertion pointing to a PIN Pass NV Index.

A PIN Pass's *pinLimit* is the number of correct authorization attempts that are permitted before authorization via *authValue* is locked out. If *pinCount* is less than its *pinLimit*, *pinCount* is incremented immediately by the TPM after *authValue* authorization succeeds. There is no automatic reset or decrement method for *pinCount*. Once *pinCount* equals *pinLimit*, an administrator must reduce *pinCount* and/or increase *pinLimit* using TPM2_NV_Write or delete the Index.

37.2.8.2 Localized Dictionary Attack protection with PIN Fail

It is possible to authorize a particular key or object via an *authValue* (PIN) that has its own individual Dictionary Attack defense and does not use (and is not affected by) the TPM's global Dictionary Attack defense mechanism. This may be useful when a TPM is used to emulate a smartcard, for example.

A key or object has localized Dictionary Attack protection if its policy has a TPM2_PolicySecret assertion pointing to an PIN Fail NV Index.

A PIN Fail's *pinLimit* is the number of incorrect authorization attempts that are permitted before authorization via *authValue* is locked out. If *pinCount* is less than its *pinLimit*, *pinCount* is incremented immediately by the TPM after *authValue* authorization fails. *pinCount* is reset to zero by the TPM whenever *authValue* authorization succeeds.

37.2.8.3 PIN Index Attributes

A PIN Index may be read or write locked. If read or write locked, the Index may still be referenced by TPM2_PolicySecret(). An Index disabled using *phEnableNV* (if platform created) or *shEnable* (if owner created) cannot be used in a policy. If a policy points to an unwritten PIN Pass or PIN Fail Index, the Index's authorization check must fail because *pinLimit* is not written.

NOTE 1 Allowing a PIN Index to be used when write locked allows it to be used as a PIN but prevents writing of the *pinLimit*.

TPMA_NV_ORDERLY may be SET or CLEAR, however, if SET the Index will revert to unwritten on TPM Reset and possibly on TPM Restart (depending on TPMA_NV_CLEAR_STCLEAR). This will cause the Index to not be usable for PIN authorization until it is reinitialized.

TPM2_PolicyAuthValue() and TPM2_PolicyPassword() cannot be used in the policy that does the initial write to a PIN Index. This is because these policy commands require that the *authValue* of the PIN Index to be used and the *authValue* of a PIN Index cannot be used until it is first written. Therefore, it may be desirable that TPMA_NV_POLICYWRITE is SET so that the PIN Index value may be initialized.

If TPMA_NV_POLICYREAD, TPMA_NV_PPREAD, or TPMA_NV_OWNERREAD is SET then the Index may read using TPM2_NV_Read (with those authorizations) without affecting the contents of the Index. If TPMA_NV_AUTHREAD is the only method of reading the Index, then the act of reading the Index could change its *pinCount.*

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

NOTE 2 Using the NV Index authorization value for the read would consume a PIN Pass Index authorization or reset the PIN Fail *pinCount*. In addition, *authValue* can't be used for authorization once *pinCount* >= *pinLimit*.

NOTE 3 In a PIN Fail Index, it may be desirable that TPMA_NV_AUTHREAD is SET, so *pinCount* can be reset by reading the NV Index with valid *authValue* authorization.

TPMA_NV_AUTHREAD is SET, so pinCount can be reset by reading the NV Index with valid authValue authorization.

It is recommended that the Index have a policy that includes a PolicySigned assertion, to unambiguously identify the Index and the entity authorized to initialize the Index.

NOTE 4 This prevents covert attacks where an Index is secretly deleted and replaced.

If the *authObject* parameter of TPM2_PolicySecret() references a PIN Pass Index, then the command may succeed, but a NULL ticket will be returned. The reason is that the ticket could allow more accesses to a count limited object than allowed by the PIN Pass Index.

NOTE 5 Without this restriction, a caller could get a ticket for a count limited object and use the ticket instead of using the PIN Pass Index. This could, potentially, allow unlimited access to a PIN Pass entity.

If a PIN Pass or PIN Fail Index is referenced as a bind object, the TPM must return TPM_RC_HANDLE. Otherwise, the sequence in which the TPM processes authorizations would enable a hammering attack on the Index.

Restrictions on PIN Pass and PIN Fail Indexes are specified in Part 3 TPM2_NV_DefineSpace.

37.3 Owner and Platform Evict Objects

In some applications, it is desirable for an object to be made persistent in the TPM so that it is always available. An example of when this would be useful is for a Primary Key. Having the Primary Key be always available avoids the time penalty of re-computing the Primary Key after each TPM Reset.

TPM2_EvictControl() is used to make a loaded object persistent by saving it to the TPM's NV memory. This command is also used to remove a persistent object.

To be made persistent, an object needs to have both public and private portions loaded; the object cannot be in the NULL hierarchy, the object cannot have the *stClear* attribute SET, and the object cannot be a descendant of a key with the *stClear* attribute SET.

The type of the *objectHandle* parameter of TPM2_EvictControl() determines if the Object is to be made persistent or to be removed from persistent memory. If *objectHandle* is a Transient Object, it is made persistent and, if *objectHandle* is a persistent object, it is deleted. The Transient Object is not affected.

When making a Transient Object persistent, the *persistentHandle* parameter of TPM2_EvictControl() indicates which handle is to be assigned to the persistent version of the object. The TPM will not allow assignment of a persistent handle if that handle is already assigned to a persistent object.

If *objectHandle* is a Transient Object in the Platform Hierarchy, Platform Authorization must be provided. If *objectHandle* is in the Endorsement or Storage Hierarchy, Owner Authorization is required.

The persistent handle space is divided evenly between the Platform and the Owner. The persistent handles that may be assigned when Owner Authorization is provided are in the range $81\ 00\ 00\ 00_{16}$ to $81\ 7F\ FF\ FF_{16}$. Handles in the range $81\ 80\ 00\ 00_{16}$ to $81\ FF\ FF\ FF_{16}$ may be assigned when Platform Authorization is provided. When removing a persistent object, the authorization used to persist the object is required to remove it.

37.4 State Saved by TPM2_Shutdown()

37.4.1 Background

TPM2_Shutdown() is used for an orderly shutdown of the TPM. When doing an orderly shutdown, the TPM will save some state to NV memory. In the reference implantation, the state saved is separated into three groups:

1) NV Orderly Data – data that is saved on any Shutdown and is not reset,
2) NV Clear Data – data that is saved on Shutdown(STATE) and is reset on TPM Restart or TPM Reset (such as, PCR), and
3) NV Reset Data – data that is saved on Shutdown(STATE) and is reset on TPM Reset (such as session context tracking information).

37.4.2 NV Orderly Data

The data in this structure is saved to NV on any Shutdown type and restored on any Startup. It may have special initialization performed if the Startup is not orderly. In the reference implementation, this data is collected into a special data structure (ORDERLY_DATA) the contents of which are illustrated in Table 31.

Table 31 — Contents of the ORDERLY_DATA Structure

Parameter	Description	Changed By:
clock	This is the version of *Clock* that is updated on any Shutdown and on any rollover of the RAM version of *Clock*.	TPM2_Clear(), TPM2_Startup(), passage of time
clockSafe	used to determine the *Safe* value reported in the TPMS_CLOCK_INFO structure. This value is CLEAR when a Startup is not orderly and once CLEAR, is not SET until the RAM value of *Clock* rolls over.	TPM2_Clear(), TPM2_Startup(), passage of time

37.4.3 NV Clear Data

Data in this structure is saved to NV on any Shutdown(STATE) but is set to its default initialization value if the subsequent Startup is either TPM Reset or TPM Restart. In the reference implementation, data of this type is collected into a single data structure (STATE_CLEAR_DATA) as illustrated in Table 32.

NOTE The default reset value is applied on either TPM Reset or TPM Restart. These change conditions are not listed in the “Changed By” column.

 Copyright © TCG 2006-2020

Table 32 — Contents of the STATE_CLEAR_DATA Structure

Parameter	Description	Changed By
shEnable	the enable for the storage hierarchy. The default initialization value is SET.	TPM2_HierarchyControl()
ehEnable	the enable for the endorsement hierarchy. The default initialization value is SET.	TPM2_HierarchyControl()
phEnableNV	the enable for the platform hierarchy NV indices. The default initialization value is SET.	TPM2_HierarchyControl()
platformAlg	the hash algorithm used for *platformPolicy.* The default initialization value is TPM_ALG_NULL	TPM2_SetPrimaryPolicy()
platformPolicy	the policy used if the authorization session is a policy session and the authorized handle is TPM_RH_PLATFORM. The default initialization value is an Empty Buffer.	TPM2_SetPrimaryPolicy()
platformAuth	the authorization value used if the authorization handle is TPM_RH_PLATFORM and the authorization is provided by password or an HMAC session. . The default initialization value is an Empty Buffer.	TPM2_HierarchyChangeAuth()
pcrSave	a data structure that holds the PCR that are preserved across Startup(STATE). The PCR in this structure are determined by a platform-specific TPM specification. . The default initialization value for each PCR is determined by the relevant platform-specific specification but is normally a Zero Digest for each PCR in the structure.	TPM2_PCR_Extend(), TPM2_PCR_Event()

37.4.4 NV Reset Data

Data in this structure is saved to NV on any Shutdown(STATE) and restored by a subsequent Startup of any type. In the case of a TPM Reset, the values are set to their specified initialization value. In the reference implementation, data of this type is collected into a single data structure (STATE_RESET_DATA) as illustrated in Table 33.

Table 33 — Contents of the STATE_RESET_DATA Structure

Parameter	Description	Changed By[(1)]
nullProof	proof value used with entities associated with the TPM_RH_NULL hierarchy (including all session contexts, sequences, and Temporary Objects); initialization value is from the RNG	
nullSeed	seed value used for creating Temporary Objects with TPM_RH_NULL as a parent; initialization value is from the RNG	
clearCount	a value that is incremented each time the TPM performs a TPM Restart; used to tag contexts for *stClear* objects so that they may not be reloaded after a TPM Restart; initialization value is zero	TPM2_Startup(CLEAR)
objectContextID	counter that is incremented each time an object is context saved; used to ensure that the encryption key and IV for each saved object is unique; initialization value is zero	TPM2_ContextSave()

Parameter	Description	Changed By(1)
contextArray	an array for keeping the version numbers of the associated saved session contexts; used to prevent replay of authorization sessions; each element is initialized to zero indicating that it is not assigned	TPM2_ContextLoad(), TPM2_ContextSave(), TPM2_StartAuthSession()
contextCount	the value used to set the version number for each saved context; initialization value is 0.	TPM2_ContextSave(), TPM2_StartAuthSession()
commandAuditDigest	the current command code audit digest; initialization value is an Empty Digest.	Any audited command, TPM2_GetCommandAuditDigest()
restartCount	counts the number of TPM Resume, TPM Restart, or D-RTM events. Initialization value is zero.	TPM2_Startup(), _TPM_Hash_End
pcrUpdateCounter	counts the number of changes to PCR; because this value is used in policy sessions, it is not reset until the context protections for saved session contexts are changed. Initialization value is zero	TPM2_PCR_Extend(), TPM2_PCR_Event(), TPM2_PCR_Reset()
commitCounter	the number of times TPM2_Commit() is executed; initialization value is zero.	TPM2_Commit()
commitNonce	value used to create the pseudo-random values used in two-phase signing operations; initialization value is from the random number generator.	
commitArray	bit vector used to indicate that only one first phase of a two phase signing operation has occurred; initialization value is all bits CLEAR.	sign-phase of two-phase sign, TPM2_Commit()
NOTE (1) The default reset value is applied on each TPM Reset. This change condition is not listed in the “Changed By” column.		

37.5 Persistent NV Data

The data in this category is data that is always present in the TPM. This does not mean that the data cannot be changed, but that there is always a value associated with the location. The data can be changed by a Protected Capability.

In the reference implementation, the persistent NV data is in the PERSISTENT_DATA structure. It contents are listed in Table 34. While this table shows the context of the structure in the reference implementation, it is only illustrative. An implementation may change the contents in order to satisfy the requirements of the implementation.

Table 34 — Contents of the PERSISTENT_DATA Structure

Parameter	Description	Changed By
disableClear	This value is CLEAR if TPM_RH_OWNER is allowed for authorization of TPM2_Clear().	TPM2_ClearControl(), TPM2_Clear()
ownerAlg	the hash algorithm used for the *ownerPolicy*	TPM2_SetPrimaryPolicy(), TPM2_Clear()
ownerPolicy	the policy used if the authorization session is a policy session and the authorized handle is TPM_RH_OWNER	TPM2_SetPrimaryPolicy(), TPM2_Clear()
endorsementAlg	the hash algorithm used for the *endorsementPolicy*	TPM2_SetPrimaryPolicy(), TPM2_Clear()
endorsementPolicy	the policy used if the authorization session is a policy session and the authorized handle is TPM_RH_ENDORSEMENT	TPM2_SetPrimaryPolicy(), TPM2_Clear()

Parameter	Description	Changed By
ownerAuth	the authorization value used if the authorization handle is TPM_RH_OWNER and the authorization is provided by password or an HMAC session	TPM2_HierarchyChangeAuth(), TPM2_Clear()
endorsementAuth	the authorization value used if the authorization handle is TPM_RH_ENDORSEMENT and the authorization is provided by password or an HMAC session	TPM2_HierarchyChangeAuth(), TPM2_Clear()
lockoutAuth	the authorization value used if the authorization handle is TPM_RH_LOCKOUT and the authorization is provided by password or an HMAC session	TPM2_HierarchyChangeAuth(), TPM2_Clear()
lockoutAlg	the hash algorithm used for the *lockoutPolicy*	TPM2_SetPrimaryPolicy(), TPM2_Clear()
lockoutPolicy	the policy used if the authorization session is a policy session and the authorized handle is TPM_RH_LOCKOUT	TPM2_SetPrimaryPolicy(), TPM2_Clear()
epSeed	the seed value for the Endorsement Hierarchy	TPM2_ChangeEPS()
ehProof	the proof value for the Endorsement Hierarchy. It is used to tag tickets and saved object contexts for objects in the Endorsement Hierarchy.	TPM2_ChangeEPS() TPM2_Clear()
spSeed	the seed value for the Storage Hierarchy	TPM2_Clear()
shProof	the proof value for the Storage Hierarchy. It is used to tag tickets and saved object contexts for objects in the Storage Hierarchy.	TPM2_Clear()
ppSeed	the seed value for the Platform Hierarchy	TPM2_ChangePPS()
phProof	the proof value for the Platform Hierarchy. It is used to tag tickets and saved object contexts for objects in the Platform Hierarchy.	TPM2_ChangePPS()
resetCount	a counter that increments on each TPM Reset	TPM Reset, TPM2_Clear()
totalResetCount	a value that increments on each TPM Reset. This value is used as *resetValue* in equation (52) to tag saved contexts.	TPM Reset
pcrPolicies	This structure is used when a platform-specific specification requires that update of certain PCR requires policy authorization.	TPM2_PCR_SetAuthPolicy()
pcrAuthValues	This structure is used when a platform-specific specification requires that update of certain PCR requires HMAC or password authorization	TPM2_PCR_SetAuthValue()
pcrAllocated	This structure is used when a platform-specific specification requires support for TPM2_PCR_Allocate() to change the algorithms used for PCR and the population of the PCR in each bank.	TPM2_PCR_Allocate()
ppList	In the reference implementation, this is an array of bits that is used to indicate the commands that require assertion of Physical Presence when TPM_RH_PLATFORM is used for authorization.	TPM2_PP_Commands()

 Copyright © TCG 2006-2020

Parameter	Description	Changed By
failedTries	count of the number of authorization failures for objects that are subject to Dictionary Attack protection. This value can count down if no authorization failures occur for *lockoutRecovery* time.	TPM2_DictionaryAttackLockReset(), authorization failures, passage of time (*recoveryTime*)
maxTries	the maximum value for *failedTries* before the TPM enters lockout	TPM2_DictionaryAttackParameters()
recoveryTime	the time that must pass before *failedTries* is decremented	TPM2_DictionaryAttackParameters()
lockoutRecovery	the time that must pass after an authorization failure using TPM_RH_LOCKOUT	TPM2_DictionaryAttackParameters()
lockoutAuthEnabled	when CLEAR, TPM_RH_LOCKOUT may not be used for authorization	TPM_RH_LOCKOUT auth failure, passage of time (lockoutRecovery)
orderlyState	between a TPM2_Shutdown() and _TPM_Init, no TPM command caused a change to the TPM's state to make the state in NV inconsistent with the state in TPM RAM	many
auditCommands	in the reference implementation, a bit array indicating which commands are audited	TPM2_SetCommandCodeAuditStatus()
auditHashAlg	the hash algorithm used for the command audit	TPM2_SetCommandCodeAuditStatus()
auditCounter	a counter that increments on the first audited command following a reset of the command audit digest. The count is only incremented if the command completes with TPM_RC_SUCCESS.	audited command
algorithmSet	this is a vendor-specific value that indicates the algorithm set that is in use on the TPM. This value may be used selectively to disable algorithms implemented in the TPM.	TPM2_SetAlgorithmSet()
firmwareV1	the more significant 32-bits of the vendor-assigned, firmware revision	TPM2_FieldUpgradeStart(), TPM2_FieldUpdradeData()
firmwareV2	the less significant 32-bits of the vendor-assigned, firmware revision	TPM2_FieldUpgradeStart(), TPM2_FieldUpdradeData()

37.6 NV Rate Limiting

The TPM is allowed to limit the rate at which updates are made to NV memory. An update occurs when an NV Index is defined or undefined, when an NV Index is modified, and when the persistence of an object is changed with TPM2_EvictControl(). An NV modification is allowed for other commands in an implementation dependent way. The rate for limiting the updates is TPM dependent.

When the TPM will prevent execution of a command because it is rate-limiting NV updates, the TPM will return TPM_RC_NV_RATE. This code is in the group of warning return codes meaning that the command might succeed if retried later.

NOTE 1 Checking to see if the NV is being rate limited may occur at any part of the command execution. This means that the TPM may return TPM_RC_NV_RATE before it has validated all of the parameters of the command. As a consequence, when the command is retried when the TPM is not rate limiting, it may fail due to incorrect parameters.

 Copyright © TCG 2006-2020

TPM2_GetCapability() with *capability* = TPM_CAP_PROPERTIES and *property* = TPM_PT_NV_WRITE_RECOVERY will provide an estimate of the number of milliseconds before the TPM will be able to accept a command that will modify the TPM NV.

NOTE 2 After TPM2_Shutdown(), any command is allowed to cause a change of the TPM's orderly shutdown state and the TPM may return TPM_RC_NV_RATE in response to commands that are not normally allowed to make modifications to the TPM NV state.

37.7 NV Other Considerations

37.7.1 Power Interruption

A TPM is not required to maintain the integrity of the data in an NV Index if a power loss interrupts the write. After the interruption, the TPM should indicate that the Index no longer exists. The interruption of a write to one Index is not allowed to affect the integrity of other Indices.

37.7.2 External NV

37.7.2.1 Introduction

An implementation is allowed to use an external device for storing non-volatile TPM data. This may include all application defined NV (NV Indices and persistent objects) as well as all TPM state data. When stored in an external device, the data is required to be encrypted, integrity checked, and rollback protected using algorithms that have the highest security strength of any algorithm implemented on the TPM.

The encryption keys used to encrypt the data in the NV shall be protected in a manner which is defined by the TPM profile which is being implemented. The level and manner of protection for these keys shall also be specified and shall be at least as strong as the keys themselves. For a chip-based implementation, the encryption keys used to encrypt the data stored in NV are not allowed to be exposed outside of the TPM, even if encrypted.

The protection keys used to protect external NV data will be contained in or derived from a persistent value that does not leave the physical TPM. That persistent value must not be a global secret.

NOTE In many implementations, it is expected that the persistent values will be stored in fuses.

37.7.2.2 Access Interruptions

When an external device is used for non-volatile storage, that device may not always be accessible to the TPM command execution engine. When the memory is not accessible, operations that require update of NV will return TPM_RC_NV_UNAVAILABLE.

NOTE When updates to NV are being rate limited (but the NV is accessible), the TPM will return TPM_RC_NV_RATE.

During the time when NV is not available for update, *Clock* should not advance and *Safe* should be NO when accessed.

When NV is not available, the implementation may or may not advance *Clock.* If *Clock* is not being advanced, the TPM will return TPM_RC_NV_UNAVAILABLE for commands that do comparisons to *Clock* or adjustments of *Clock.* These commands are:

- TPM2_PolicySigned() or TPM2_PolicySecret() with a non-zero *expiration*;

 Copyright © TCG 2006-2020

- TPM2_PolicyTicket(); and
- TPM2_PolicyCounterTimer() if any part of TPMS_TIME_INFO.*clockInfo.clock* is used in the operation.

When NV is not available, the implementation may or may not advance *Time*. If *Time* is not being advanced, then TPM2_PolicyCounterTimer() will return TPM_RC_NV_UNAVAILABLE if any part of TPMS_TIME_INFO.time is used in the operation.

37.7.3 PCR in NV

If a TPM implementation places PCR in NV space, it should also use a caching scheme to prevent NV wearout.

 Copyright © TCG 2006-2020

38 Multi-Tasking

An implementation of the TPM may use cycles of a host processor for execution. The operating system on the host processor may not be able to operate properly if the TPM uses large blocks of time to complete execution of a command. In such systems, the TPM may be designed to yield after completion of a portion of the command so that the command may be resumed later.

When the TPM yields before completion of a command, it may return TPM_RC_YIELDED. This code indicates that the exact command that the TPM was executing may be resubmitted later. If the next command to the TPM is not the yielded command, the TPM may lose any state associated with the command that yielded so that when the yielded command is restarted, it may restart from the beginning.

 Copyright © TCG 2006-2020

39 Errors and Response Codes

39.1 Error Reporting

When a command fails, the TPM will return a 10-octet response that indicates the response code. No auxiliary information is provided by an error other than what may be inferred from the context of the error.

39.2 TPM State After an Error

When the TPM returns an error that is related to command execution, the TPM is required to preserve the TPM state. Except for the possible effect on the dictionary attack logic, it should be as though the command had not been received.

In some cases, an otherwise asynchronous operation may cause the TPM to create an error. For example, if the TPM is doing self-test of functions on an as-needed basis, the TPM may return an error due to failure of the self-test. The TPM should preserve the fact that it has failed the self-test but it should not preserve any command-specific results.

When a command modifies NV RAM, the action of writing the NV may fail and it may not be recoverable. If the TPM cannot recover from the NV write failure, then it should disable the NV so that the affected NV locations cannot be accessed.

39.3 Resource Exhaustion Warnings

39.3.1 Introduction

The executable specification has been optimized for comprehension and correctness. In particular, the reference implementation has been designed to minimize the locations in the code where resource exhaustion can occur, so that recovery from these situations is simplified. This is known not to achieve an efficient use of limited RAM resources, and other implementations may choose methods that are more aggressive in their use of memory. These implementations will invariably have error conditions that are not covered in the normative clauses of the reference implementation. This clause describes the methods that are recommended for reporting of these errors.

Allocated resources are classified by their persistence relative to a command's execution. A transient resource is one that can be moved to or from TPM memory using a context management command (TPM2_ContextLoad(), TPM2_ContextSave()). These resources may continue to occupy TPM memory after completion of a command. A temporary resource is used in the processing of a command but is disposed of before the command completes. The following two clauses describe the expected behavior of the TPM when it is unable to create either of these resource types.

39.3.2 Transient Resources

The TPM reference implementation allocates space for a configuration-defined number of transient resources of the maximum size supported by the configuration parameters. This allocation occurs during the compilation process of the reference implementation. The maximum size of the objects is determined by the structure definitions in TPM 2.0 Part 2. The reference implementation presumes that, if a resource slot is available, then any object that might be stored in that slot will fit.

A practical consequence of this approach is that the only resource allocation failure for a transient resource occurs when all the dedicated slots of the appropriate type (object, sequence object, or session) are full. For objects, the number of available slots determines when the resources are all used. For sessions, there are two slot resources: handles and session contexts.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

When the TPM is out of object slots, it returns TPM_RC_OBJECT_MEMORY. When out of session context slots, it returns TPM_RC_SESSION_MEMORY. When the TPM is out of handle slots for sessions, the response code is TPM_RC_SESSION_HANDLES.

For a system using dynamic allocation of memory for transient resources, the TPM should return an error response code that indicates the type of resource that needs to be removed from the TPM for the command to complete. If removal of either an object or a session from TPM memory would free memory for the command, then the TPM may return TPM_RC_MEMORY. If removal of a specific resource is required, the TPM should return a code that indicates the specific resource (TPM_RC_OBJECT_MEMORY or TPM_RC_SESSION_MEMORY).

39.3.3 Temporary Resources

The TPM reference implementation is designed so that temporary resources are allocated on the execution stack. Static analysis of the code allows the maximum size of the stack to be determined so that resource exhaustion for a temporary resource cannot occur.

This construction vastly simplifies the control flow of the normative command actions, since no additional memory management code is required. However, other memory management schemes for temporary resources are allowed. Error handling for these implementations is complex and beyond the scope of this specification. However, the TPM is required to follow the standard error reporting rules.

- If the TPM returns an error, the state of the TPM is required to be restored to the state that existed before the command execution began.

NOTE 1 One exception is state that would change even if a command were not executed, such as *Clock*, *Time*, dictionary attack lockout recovery, and related state. Another exception is state deliberately changed as a result of the error, such as the count of authorization failures and NV PIN Fail index values.

- The TPM will return TPM_RC_MEMORY if removal of one or more transient resources will allow the command to complete.

NOTE 2 If the TPM requires the removal of a specific type of resource, then it should return the specific response code (TPM_RC_SESSION_MEMORY or TPM_RC_OBJECT_MEMORY) rather than the non-specific TPM_RC_MEMORY response.

- If a session must be flushed before a new session can be created, the TPM will return TPM_RC_SESSION_HANDLES.

The consequence of these requirements is that the TPM is required to be able to return the memory allocation to the same state that existed before the command execution began. It is also required that no change to NV memory be made before all temporary resources required for completion of the command have been allocated.

39.4 Response Code Details

The response code from the TPM is a 32-bit value but the TPM only uses the low-order 12 bits to communicate its warnings or errors, leaving the remaining 20 bits for use by software.

The response codes are encoded so that certain errors can be associated with the component in which the error occurred, and the specific element of the component. In cases where the error cannot be associated with a specific parameter of the command, the response code will be sufficiently differentiated to allow determination of the cause of the error.

EXAMPLE 1 If the second handle in the handle area was the wrong type for the command, the TPM would return TPM_RC_VALUE + TPM_RC_H + TPM_RC_2.

 Copyright © TCG 2006-2020

EXAMPLE 2 If the TPM can determine that the error was in the handle area but not the handle in error, the TPM would return TPM_RC_VALUE + TPM_RC_H.

The design of the response codes was constrained so that the response codes returned for commands defined in this specification would be different from the response codes defined by the previous version of the specification, TPM 1.2. This constraint leads to a layout that satisfies the requirements but is not intuitive.

An algorithm for evaluating the response code to determine the nature of the error and the command handle, session, or parameter value in error is shown in the Figure 27 flow chart.

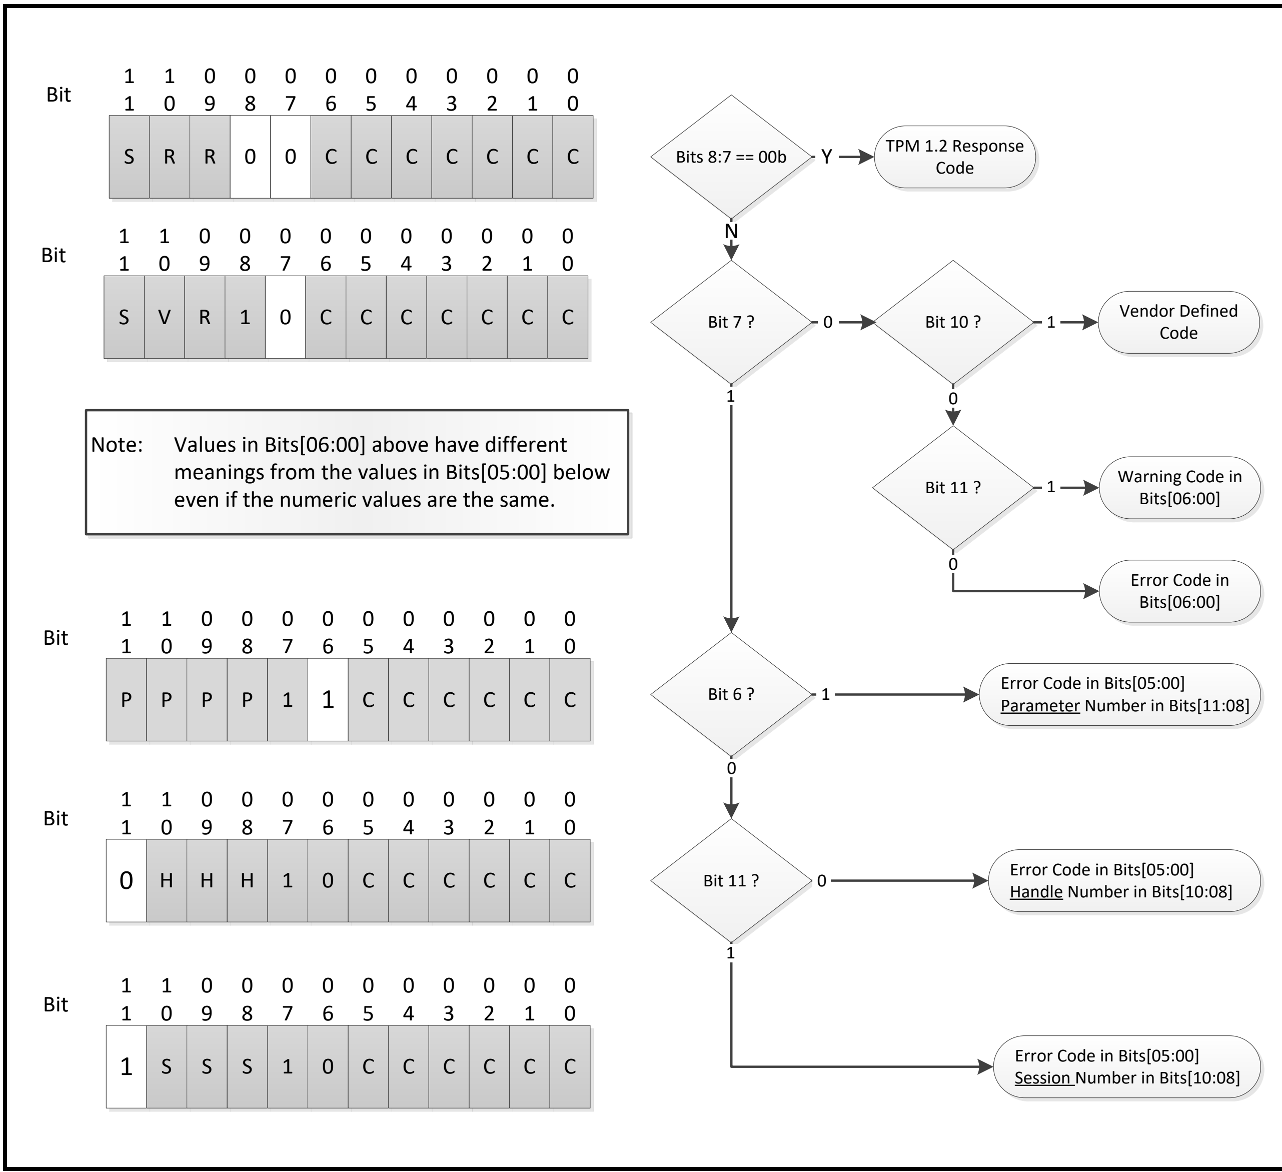

Figure 27 — Response Code Evaluation

40 General Purpose I/O

A TPM may have one or more I/O pins that inputs or outputs a logic state. TPM2_NV_Read and TPM2_NV_Write may be used to access the value of GPIO using normal access controls.

A platform-specific specification defines the mapping of NV Indices to individual General Purpose I/O (GPIO). Whether the TPM reserves any NV storage for the indicated GPIO is platform specific.

This specification does not require the NV Indices associated with GPIO pins to be pre-allocated. When one of the Indices reserved for GPIO pins is defined, it is automatically associated with the corresponding GPIO pin.

NOTE 1 The owner and platform space are segregated and it is expected that the GPIO pins will be assigned to Index values in the Index space reserved for the platform.

NOTE 2 The TCG maintains a registry of reserved NV Index values.

The controls that let the GPIO pin be used either as an input or an output are vendor or platform specific.

For outputs, if the Index has the TPMA_NV_ORDERLY attribute SET, the output state is volatile, and becomes non-volatile on an orderly shutdown. If the TPMA_NV_ORDERLY attribute is CLEAR, the output state is non-volatile.

For inputs, a read of the Index returns TPMI_YES_NO, where YES indicates a logic 1 and NO indicates a logic 0 on the input pin.

 Copyright © TCG 2006-2020

41 Minimums

41.1 Introduction

This clause lists the minimums for specific functional blocks where a minimum is needed to ensure proper TPM operation.

Platform-specific TPM specifications may impose other minimums but those minimums are not allowed to be less than the minimums in this specification.

41.2 Authorization Sessions

An active authorization session is a session that is currently loaded into TPM memory and can be addressed with a session handle in a command. A concurrent session is an authorization session that either is loaded on the TPM or has its context saved.

A command may require no more than three sessions divided according to the needs of the command. The TPM is required to be able to support execution of a command with three authorization sessions.

The management of sessions is different from the management of objects. Management software can keep the contexts for an indefinite number of objects and load them as required. The number of concurrent sessions, however, is limited by the resources that the TPM can devote to tracking those sessions.

The TPM should support a minimum of 64 concurrent sessions. Fewer sessions would impair the ability of the TPM to conduct concurrent operations with multiple users.

41.3 Transient Objects

In order to be able to execute all commands, the TPM needs to have two active, loaded objects of any type. A Transient Object is an object that occupies TPM memory and may be referenced by handle. The number of Transient Objects that the TPM supports does not include those objects that have been placed in persistent TPM memory.

NOTE A TPM implementation may copy an object from persistent storage into a Transient Object slot in order to speed up access to the object data.

41.4 NV Counters and Bit Fields

All TPM implementations should allow at least one NV Index to be allocated for use as a monotonic counter (TPMA_NV_COUNTER) or bit field (TPMA_NV_BITS). The number of these Index types determines how many different policies may include revocation as part of their logic. When the number of these Index types is too small, the software complexity of handling revocation becomes too complex to manage.

NOTE 1 This minimum (1) may be adequate for a TPM in a simple embedded system but is too low for a TPM in a complex system such as a PC. Platform-specific specifications for more complex systems should mandate support for at least sixteen (16) counter or bit field Indices.

NOTE 2 The requirement that a TPM support the TPMA_NV_COUNTER or TPMA_NV_BITS attribute implies that the TPM is required to implement either TPM2_NV_Increment() or TPM2_NV_SetBits().

 Copyright © TCG 2006-2020

42 Attached Components

42.1 Introduction

42.1.1 Purpose

The TPM has an extensive set of commands that allow implementation of flexible access control for objects contained in the Shielded Locations of the TPM. The pair of commands TPM2_AC_Send() and TPM2_Policy_AC_SendSelect() enable the access control mechanisms of a TPM to be used to manage sensitive data (such as keys) for other components (called the Attached Components) that are attached to the TPM.

Examples of Attached Components are encrypting disk controllers, crypto accelerators, and network adapters with crypto capabilities.

42.1.2 Concept

An Attached Component (AC) is physically connected to a TPM through a data channel other than the TPM's command and response buffer (the details of the TPM-to-AC data channel are beyond the scope of this document). A properly authorized TPM2_AC_Send() will cause the TPM to copy the selected TPM Object to a selected AC over the provided data channel. This avoids having to "bounce" the Object via an out of band transfer from the TPM through memory then to the component. Object data is, therefore, duplicated outside the TPM's "Shielded Location". The platform manufacturer provisions the connection between the TPM and the Attached Component, and hence determines the protection of an object in transit from the TPM to the Attached Component.

TPM2_AC_Send() uses the DUP auth role that requires authorization with a policy with *policySesssion→commandCode* set to TPM_CC_AC_Send.

NOTE TPM2_AC_Send() will only send objects that are constructed with a policy that allows TPM2_AC_Send().

42.2 TPM2_AC_Send()

TPM2_AC_Send() instructs the TPM to copy portions (possibly all) of the Object referenced by *sendObject* to the Attached Component referenced by *ac*. The methods used to send the Object and the properties of the Attached Component are outside the scope of this specification. The command does not cause the referenced object to be flushed.

The applications using this TPM and the creators of the TPM's objects are expected to understand the properties of the Attached Component and the connection between the TPM and the Attached Component.

The use of Enhanced Authorization allows the object creator to restrict sending the object using any combination of Policies. For example, the policy may only allow an Object to be sent when PCR and Locality have specific values. TPM2_AC_Send() requires DUP role authorization for the *sendObject.* This means that *sendObject* authorization requires a policy session that has *policySession→commandCode* set to TPM_CC_AC_Send. This requirement ensures that TPM2_AC_Send() is only used on Objects that are intended to be sent to an Attached Component.

The *acDataIn* parameter allows TPM2_AC_Send() to send qualifying data to an Attached Component along with the Object. For example, *acDataIn* may be used to identify a key slot in the AC into which the Object is to be loaded.

An Attached Component optionally returns *acDataOut* information to the caller. A possible use of *acDataOut* would be for the AC to indicate the key slot into which it has placed the Object.

After TPM2_AC_Send() completes, the Object in the TPM may be flushed without effecting the values in the AC. Similarly, the AC may modify (or delete) the Object data from its memory without affecting any Object in TPM Shielded Locations.

42.3 Send Object Types

The TPM does not restrict the type of Object that may be sent to an AC. However, an AC may not be able to process all types of TPM Objects. The AC may be designed to reject unknown Object types or it may be the responsibility of system software to ensure that only the proper Object types be sent to an AC.

42.4 Send Object Attributes

The *sendObject* shall have *fixedTPM*, *fixedParent* and *encryptedDuplication* CLEAR.

42.5 Attached Component Authorization

TPM2_AC_Send() requires authorization for the Object to be sent and for the AC that is the target of the send operation.

EXAMPLE If an Attached Component is an encrypting disk controller, unauthorized software, such as ransomware, cannot set the encryption key without getting access to the proper authorization. Use of the PCR as part of the policy for the object can ensure that the disk encryption key can only be set early in the boot phase.

Proper authorization to send to an AC is determined by the presence of an aliased NV Index. The range of AC handles is AC_FIRST to AC_LAST. The range for aliased AC Indexes is NV_AC_FIRST to NV_AC_LAST. If the Owner or Platform creates an NV Index in the range AC Indexes and a corresponding AC exists in the AC handle range, then the write authorization settings of the AC Index (TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and TPMA_NV_POLICYWRITE) determine how the send may be authorized. If no aliased AC Index exists, then either Owner Authorization or Platform Authorization may be used to allow the send to the AC.

The Platform and Owner may use TPM2_NV_DefineSpace() to delegate the rights to access a specific AC The Platform or Owner may change the access rights to the AC by calling TPM2_NV_UndefineSpace() and then TPM2_NV_DefineSpace() with new parameters.

TPM2_NV_ChangeAuth() allows the current key and object manager to change the *authValue* by using the current AC authorization policy.

The following is a summary of states and allowed actions:

a) Attached Component has no aliased NV Index defined
    1) Can use TPM2_AC_Send() to send objects to the Attached Component with *ownerAuth* or *platformAuth*
    2) Can use TPM2_AC_GetCapability() to get optional information about the AC
b) Attached Component has an aliased NV Index
    1) Can use TPM2_AC_Send() to send objects to the Attached Component with the write authorization types allowed by the aliased Index.
    2) Can change authorization using ADMIN role (TPM2_NV_ChangeAuth()).

TPM2_Clear will delete any AC Index alias defined by the Owner but not by the Platform.

42.6 Attached Component Object Management

42.6.1 Discovery

Applications may use information from the platform manufacturer (for example, a platform certificate) to determine whether a platform has an Attached Component. Software may also discover the number of attached components by calling TPM2_GetCapability(TPM_CAP_HANDLES) with a TPM_HT_AC Property Type to find available AC handles.

Specific information about each Attached Component may be provided by calling the TPM2_AC_GetCapability() command. In response to this command, the TPM returns vendor-specific information about a specific Attached Component. For example, *capabilitiesData* may be used to return a pairing value that can be also obtained from the AC itself by an AC-specific API (see Part 2, *Attached Component Structures*).

The association between ACs and AC handle is vendor specific, but the association is required to be constant during the platform's lifetime. If an AC is replaced, the new AC should have the same AC handle as the AC that was replaced.

After reboot or other TPM power state changes, TPM2_GetCapability() should be used to obtain the list of the available ACs.

NOTE 1 It is suggested that no handle be associated with a defective AC. However, it is also allowed that a defective AC be reported using TPM2_AC_GetCapability().

TPM2_GetCapability() can be used at any time to determine the current AC configuration.

NOTE 2 There is no mechanism for the TPM to proactively signal the change in state of an AC. However, a platform may have a method for the AC to signal software and for that indication to trigger an enumeration process.

42.6.2 Setup

The AC's configuration should be performed by the AC's Manufacturer. AC configuration is out of scope of the TCG.

42.6.3 Sending

If the desired Object is not already loaded, the application (such as a key manager) may load it using an existing TPM2 command such as TPM2_Load(). This removes the wrapping of the object and returns an object handle. However, if an object is evicted and then re-loaded, there is no assurance the TPM will assign the object the same object handle. For this reason, applications should not associate the TPM's assigned object handle with the object when sent to the Attached Component, or when the object is within the Attached Component's domain. Key and object managers using the TPM2_AC_Send() command may assign, if necessary, a handle for the transferred object within the Attached Component domain using the *acDataIn* parameter. Therefore, in common usages there is no association between the TPM generated object handle assigned to the object and any handle for that object within the Attached Component's domain. Any association between the TPM's object and the Attached Component's object is done by the application or the application's resource and object manager external to the TPM.

 Copyright © TCG 2006-2020

42.7 Power States

The AC authorization values and policies that are setup by TPM2_NV_DefineSpace() are persistent across all TPM power state changes, like the authorization values and policies of other NV Indexes.

TPM power state changes have no effect on the Attached Component's copy of objects, because that copy of the object is no longer in the TPM's "Shielded Location".

42.8 Attached Component Format

The format and security properties of the connection between the TPM and the Attached Component are outside the scope of the TPM Library Specification. A vendor may provide a proprietary connection between the TPM and an Attached Component where the format and the security properties are defined by that vendor. A TCG platform-specific Working Group may define a data format that may include a key exchange method so that independently manufactured Attached Components can interoperate with different TPMs.

43 Authenticated Countdown Timer (ACT)

43.1 Introduction

The functionality and commands described in this clause enable the TPM to manage multiple authenticated countdown timers (ACT).

43.2 Description

An ACT is a 32-bit counter that, when not already zero, will decrement by one each second that the TPM is powered.

The countdown timers are used to trigger events on a platform when they count down to zero, at which point they are said to timeout or expire. TPM2_ACT_SetTimeout() is used to set an ACT to a non-zero value and begin the timeout. On TPM Reset or TPM Restart, all ACT timeouts are set to zero with no side effects (no event triggered). ACT timeouts are preserved across TPM Resume.

The ACT timeouts are saved by TPM2_Shutdown(STATE). On TPM2_Startup(STATE), if the TPM shutdown was orderly, the saved ACT values are restored and the ACT resumes counting. If an ACT *startTimeout* has been written (TPM2_ACT_SetTimeout()) since the last TPM2_Startup(), then the current timeout of the ACT is saved by TPM2_Shutdown(STATE); otherwise, the saved value is one half of the current ACT timeout. If a TPM2_ACT_SetTimeout() occurs after the TPM2_Shutdown(), then the TPM state is no longer orderly, and a subsequent TPM2_Startup(STATE) will fail.

An ACT has an *authValue* and an *authPolicy*. The *authValue* is the same as the current *platformAuth* and can only be used if *phEnable* is SET. The *authPolicy* is ACT-specific and is neither enabled nor disabled by *phEnable*. Each ACT has its own *authPolicy*.

NOTE 1 A system might continue to operate after a TPM2_Shutdown(STATE). Therefore, saving half the timeout prevents an attacker from continually extending the timeout by doing TPM2_Shutdown(STATE) immediately after TPM2_Startup(STATE), and then restarting the system (TPM Resume) just before the timer expires.

TPM2_ACT_SetTimeout() must be properly authorized. Authorization may be provided either by *platformAuth* or by an ACT-specific *authPolicy*. The *startTimeout* parameter in TPM2_ACT_SetTimeout() is an integer number of seconds.

The *authPolicy* for an ACT can be changed by TPM2_SetPrimaryPolicy() using either *platformAuth* or the ACT-specific *authPolicy*.

The *authPolicy* of an ACT is initialized to an Empty Policy by TPM Reset or TPM Restart but is preserved during TPM Resume.

NOTE 2 After TPM Reset or TPM Restart, *phEnable* is SET, allowing the platform to initialize any ACT *authPolicy*.

43.3 Typical Use

A typical example for the use of an ACT is as a watchdog timer that will cause a platform reset when the timer reaches zero (expires). In a system using an ACT, a periodic platform action outside the TPM indicates that the timeout should be set anew using TPM2_ACT_SetTimeout(). The most common reason why timeout is not set anew is that the local system is not behaving properly because of some type of corruption (either inadvertent or malicious). The intent of the timer is that, in the absence of a properly authorized timeout extension, the platform would be reset, putting it back into a known state with the

 Copyright © TCG 2006-2020

expectation that the corruption can be removed. The reason for having an authenticated timeout is to allow an external entity to make a decision about the health of the system.

The example above is not the only one supported by an ACT. In fact, this specification does not mandate that any specific platform behavior occur as a result of a timer expiring. The action on timer expiration may be chosen by a platform-specific specification or be vendor specific.

Because *platformAuth* may be used to change the *authPolicy* or set a *startTimeout* for any ACT, the platform firmware has ultimate control of the ACT. On each TPM Reset or TPM Restart, the platform firmware is expected to set the *authPolicy* for all ACT using *platformAuth*. This specification mandates no specific policy for any ACT, but it is expected that, in most cases, the platform firmware will either:

a) Initialize an ACT *authPolicy* with a policy that can only be satisfied by an entity trusted by the platform manufacturer; or
b) Initialize the ACT *authPolicy* so that the *authPolicy* can be changed using *ownerAuth.*

In case a), the platform firmware may set an initial timeout to ensure that some corrective action will occur if malware prevents the trusted entity from setting the ACT.

NOTE 1 This is how the platform would typically initialize a watchdog timer

In case b), the system software is expected to take control of the ACT. The platform would not set an initial timeout as it is possible that the ACT will not be used by the system software.

NOTE 2 If the platform firmware does not initialize the ACT *authPolicy* before *phEnable* CLEAR, then the ACT cannot be used.

43.4 Failure Mode

If the TPM enters failure mode, the ACT should continue to count down and trigger the specified event should it expire.

NOTE 1 If the failure mode was caused by a timer failure or affects functionality which is required for the platform-specific event, the ACT might not trigger reliably.

TPM2_ACT_SetTimeout() shall not be usable while a TPM is in Failure Mode. This means that the timeout cannot be extended and that timed events will occur if the TPM is not powered down or Reset before the ACT expires. A platform-specific specification may specify that an event will have no effect if the TPM is in Failure Mode.

A TPM may allow reading of the remaining ACT time (TPM2_GetCapability(*capability* = TPM_CAP_ACT) when the TPM is in Failure Mode.

43.5 Field Upgrade

The behaviour of a TPM during Field Upgrade is undefined. However, it is preferred that ACT continue to operate normally during Field Upgrade except that the ACT may not be changed by TPM2_ACT_SetTimeout().

NOTE Since *platformAuth* is required to start a Field Upgrade, *platformAuth* can be used to set the *startTimeout* for any active ACT to a value that is sufficient to allow a Field Upgrade to complete.

 Copyright © TCG 2006-2020

43.6 Typical ACT authPolicy

This clause describes a typical ACT authorization policy that authorizes setting of *startTimeout* with an authentication credential (key). The signature created by the authentication key is used as a cryptographically protected deferral ticket for the ACT.

The ACT *authPolicy* is constructed using TPM2_PolicySigned() and may include other policy components. Authorization by multiple entities can be achieved by combining multiple TPM2_PolicySigned() commands using AND or OR terms.

The deferral ticket is provided to the TPM in TPM2_PolicySigned() as the *auth* parameter (the signed authorization). The signature verification key, the *authObject* in TPM2_PolicySigned(), may be a symmetric or asymmetric key.

NOTE The advantage of an asymmetric signing key is that only the public key needs to be provisioned into the TPM. In the case of a symmetric HMAC key, the HMAC key's *authPolicy* should restrict the key to be used only for TPM2_PolicySigned() and not for other commands like TPM2_HMAC() (i.e. the TPM should not be able to issue its own deferral tickets).

For the *nonceTPM* and *expiration* parameters of TPM2_PolicySigned(), the following is recommended:

c) *nonceTPM* present and not an Empty Buffer

d) *expiration* > 0

Both settings ensure that a deferral ticket is single-use. The presence of *nonceTPM* in TPM2_PolicySigned() prevents the same signature being used multiple times within a policy session to defer the ACT indefinitely.

NOTE The *nonceTPM* for the policy session changes at the end of TPM2_ACT_SetTimeout(). This invalidates the previous signature and prevents replay of TPM2_ACT_SetTimeout() without getting a new signature from the authorized entity.

The non-negative *expiration* prevents TPM2_PolicySigned() creating a policy ticket which may be reused with TPM2_PolicyTicket() over a period of time to defer the ACT.

The ability to change *startTimeout* of TPM2_ACT_SetTimeout() should be limited by including *cpHash* in the ACT *authPolicy*. This can be achieved in two ways:

1) The ACT authorization policy includes TPM2_PolicyCpHash(). In this case, the entity setting the policy determines the *startTimeout* value.

2) The ACT authorization policy includes TPM2_PolicySigned() with *cpHashA* set. In this case, the signer (of the deferral tickets) determines the startTimeout value.

 Copyright © TCG 2006-2020

Annex A
(informative)
Policy Examples

A.1 Introduction

This clause compares authorization between TPM 1.2 and this specification.

A.2 TPM 1.2 Compatible Authorization

A TPM 1.2 key may have its use gated by PCR and *authValue*. To select this authorization, the key would be created with a *pcrSelection* with at least one bit SET and the *digestAtRelease* set to indicate the digest of the selected PCR. Additionally, the key's TPM_AUTH_DATA_USAGE would be set to TPM_AUTH_ALWAYS. To perform the authorization, an authorization session is created and used to prove knowledge of the *authValue* in the authorization HMAC. If the HMAC check is successful and the digest of the selected PCR matches the *digestAtRelease*, the action is approved.

For a TPM compatible with this specification, use of PCR for access control requires a policy. The policy should be created at the time of object creation so that the policy requires selected PCR to have a specific value. This is similar to determining the *digestAtRelease* in TPM 1.2. The policy will use two factors: PCR and an *authValue*. The first policy command will be TPM2_PolicyPCR() and it will modify the *policyDigest* by:

$$policyDigest_1 \coloneqq \mathbf{H}_{contextAlg}\left(policyDigest_0 \mathbin{||} \text{TPM_CC_Policy_PCR} \mathbin{||} PCR\ Selection \mathbin{||} PCR\ digest\right) \quad (58)$$

where

$\mathbf{H}_{contextAlg}$	hash function using the context hash algorithm
$policyDigest_0$	an array of octets of zero equal in length to the size of the policy digest
TPM_CC_Policy_PCR	a constant indicating the command modifying the *policyDigest*
$PCR\ Selection$	a TPML_PCR_SELECTION that indicates the PCR that will be included in the PCR digest
$PCR\ digest$	the expected digest of the PCR selected by the PCR Selection; the PCR are hashed using the hash algorithm of the policy session

To cause the TPM to compute an HMAC using the *authValue* of the object, a TPM2_PolicyAuthValue() would be included in the policy. It would modify the *policyDigest* as:

$$policyDigest_2 \coloneqq \mathbf{H}_{contextAlg}\left(policyDigest_1 \mathbin{||} \text{TPM_CC_PolicyAuthValue}\right) \quad (59)$$

where

$\mathbf{H}_{contextAlg}$	hash function using the context hash algorithm
$policyDigest_1$	the result of performing the operation in equation (58) above
TPM_CC_PolicyAuthValue	the command code for TPM2_PolicyAuthValue()

The value of *policyDigest*$_2$ would be included in the template of the object in the *authPolicy* parameter.

To use the object, a policy authorization session would be started using TPM2_StartAuthSession(). Then a TPM2_PolicyPCR() and TPM2_PolicyAuthSession() would be executed using the handle of the authorization session. If the PCR were the same as those used when performing the operation of

equation (58), then the *policyDigest* of the policy session will match the *authPolicy* of the object. Because the policy sequence contained TPM2_PolicyAuthValue(), the TPM will check that the HMAC in the authorization indicates that the caller knows the *authValue* of the object (same computation as performed on an HMAC session). If both checks succeed, the object is properly authorized.

Annex B
(normative/informative)
RSA

B.1 Introduction

The RSA asymmetric algorithm is used for digital signatures, secret sharing, and encryption.

A TPM that supports RSA should support a public modulus size of at least 2,048 bits. Support for other key sizes is permitted.

NOTE 1 The reference implementation supports key sizes of 1024, 2048, and 3072.

When the size (k) of the public modulus (n) of an RSA key is given, then $\lfloor log_2 n \rfloor = (k - 1)$. Additionally, for a two-prime system, the primes (p and q) satisfy $\lfloor log_2(p^2) \rfloor = (k - 1)$ and $\lfloor log_2(q^2) \rfloor = (k - 1)$.

The RSA algorithm requires the methods of encryption and signing defined in IETF RFC 8017. This includes support for RSAES-OAEP, RSAES-PKCS1-v1.5, RSASSA-PKCS1-v1.5, and RSASSA-PSS.

The RSA structures in this specification support only public keys that are the product of two primes. Support for other numbers of primes is allowed, but it is performed in a vendor-specific manner and thus beyond the scope of this specification.

A TPM is required only to support a public exponent (e) of $2^{16}+1$. Support for other exponents is allowed but discouraged.

NOTE 2 The reference implementation does not support an exponent size smaller than 7 nor does it allow keys to be created on the TPM with a public exponent less than $2^{16} + 1$.

When loading an RSA key, the TPM validates that its public and private portions are properly paired by dividing the public modulus by the single private prime and requiring that the remainder be zero. The TPM does not validate whether input values are primes.

NOTE 3 Validating the pairing of the public and private key portions need not be performed when the key is being loaded. However, this check is performed before the authorization value of the key or the private portion of the asymmetric key may be used.

The TPM will also validate that the provided and computed prime factors are in an acceptable range. To be acceptable, the square of the prime is required to have the same number of significant bits as the public modulus.

 Copyright © TCG 2006-2020

B.2 RSAEP

This is the RSA public key primitive defined in IETF RFC 8017, clause 5.1.1. It is a modular exponentiation of a message (m) with the public exponent (e), modulo the public modulus (n) to produce the cipher text (c). This is expressed as:

$$c \coloneqq m^e \pmod n \tag{60}$$

where

c	the encrypted message
m	a value $0 < m < n$ to be encrypted
e	the public exponent (default is $2^{16} + 1$)
n	the public modulus

B.3 RSADP

This is the RSA private key primitive defined in PSCS#1v2.1, clause 5.1.2. This clause describes the private key in two forms: as a pair and as a quintuple. The reference implementation uses the pair form with a private exponent (d). Using this form, the RSADP operation recovers a message from a cipher text by:

$$m \coloneqq c^d \pmod n \tag{61}$$

NOTE The reference implementation also supports use of the CRT form of the private exponent.

B.4 RSAES_OAEP

This encryption scheme is defined in IETF RFC 8017. It is the only scheme used with an RSA-restricted decryption key. The algorithm identifier for this scheme is TPM_ALG_OAEP.

For RSA keys protecting a secret value (such as, an encryption key or a session secret), the *L* parameter is a byte stream, the last byte of which must be zero, indicating the intended use of the encrypted value. A command that accepts or creates an RSA-encrypted secret indicates the value of the string to use for *L*. The RSA key's *scheme* hash algorithm (or, if it is TPM_ALG_NULL, the RSA key's Name algorithm) is used to compute $lhash \coloneqq \mathbf{H}(L)$, and the null termination octet is included in the digest.

MGF1 (as defined in IEEE Std 1363™-2000) computes *dbMask* and *seedMask.* The mask-generation function uses the Name algorithm of the RSA key as the hash algorithm.

B.5 RSAES_PKCSV1_5

This encryption scheme is defined in IETF RFC 8017. It has no parameters. The algorithm identifier for this scheme is TPM_ALG_RSAES.

B.6 RSASSA_PKCS1v1_5

This signing scheme is defined in IETF RFC 8017. The algorithm identifier for this scheme is TPM_ALG_RSASSA.

 Copyright © TCG 2006-2020

An RSA-restricted signing key may use either this algorithm or RSASSA_PSS, but not both. An unrestricted signing key may select as its default either this algorithm or RSASSA_PSS. If TPM_ALG_NULL is selected, the caller will specify the scheme in the signing command.

This signature scheme prepends an OID to a digest before signing with the private key. It may be used in any command that allows an asymmetric signing operation.

For signing commands that use restricted signing keys, the TPM provides the OID that corresponds to the digest algorithm, and the OID provided by the caller is discarded.

For commands that use unrestricted signing keys, the TPM uses the caller-provided OID.

NOTE 1 If the command does not provide a parameter for the OID, then the TPM provides the OID even if the key is not restricted.

For hash algorithms where the TCG defines a TPM_ALG_ID, the TCG provides the OID to use with restricted signing keys. Currently, the defined values are:

- SHA1

  30 21 30 09 06 05 2B 0E 03 02 1A 05 00 04 14_{16}

- SHA256

  30 31 30 0d 06 09 60 86 48 01 65 03 04 02 01 05 00 04 20_{16}

- SHA384

  30 41 30 0d 06 09 60 86 48 01 65 03 04 02 02 05 00 04 30_{16}

- SHA512

  30 51 30 0d 06 09 60 86 48 01 65 03 04 02 03 05 00 04 40_{16}

NOTE 2 These values are from IETF RFC 8017.

NOTE 3 The listing above is not normative. TCG maintains the normative list.

B.7 RSASSA_PSS

This signing scheme is defined in IETF RFC 8017. The algorithm identifier for this scheme is TPM_ALG_RSAPSS.

A restricted signing key may use either this algorithm or RSASSA_PKCS1v15, but not both. An unrestricted signing key may use either this algorithm, RSASSA_PKCS1v15, or TPM_ALG_NULL. If TPM_ALG_NULL is selected, the caller can specify the signing scheme in the signing command.

When used with a restricted signing key, the hash algorithms for messages (M) and M' are the same.

When used with an unrestricted signing key, the hash algorithm for M and M' can differ.

For both restricted and unrestricted signing keys, the random salt length will be the largest size allowed by the key size and message digest size.

NOTE If the TPM implementation is required to be compliant with FIPS 186-4, then the random salt length will be the largest size allowed by that specification.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

B.8 RSA Key Generation

B.8.1 Background

The implementation of the RSA key-generation function should meet the requirements of the intended market. The methods in FIPS 186-3 are recommended.

In the reference implementation, the primes used for the key are generated using the methods of FIPS 186-3, B.3.3 "Generation of Random Primes that are Probably Prime."

NOTE FIPS 186-3 only allows this method to be used for primes of 1024 bits or larger. For smaller primes, the methods described in B.3.5 "Generation of Probable Primes with Conditions Based on Auxiliary Provable Primes" or B.3.6 "Generation of Probable Primes with Conditions Based on Auxiliary Probable Primes" can be used if FIPS compliance is required.

B.8.2 Large Prime Generation

For generating a prime the reference implementation has two different implementations: one using testing of candidates and the other using a number sieve. The process for testing of candidates is described in this clause.

The inputs are:

- $primeSize$ – this is the number of bits in the prime to be generated. It should be half the number of bits in the public modulus to be generated
- e – the public exponent

  NOTE 1 In the reference implementation, the exponent is required to be a prime number > 2^{16}

- a random number generation function according to the type of key being generated (see 27.6.2 and 27.6.3)

  NOTE 2 Derivation of RSA keys is not supported.

The prime generation process is:

a) set prime candidate p to the next *primeSize* number of bits from the provided random number generation function

b) adjust *p* so that the high-order two bits and the low order bit are one

   NOTE 3 In the reference implementation, when a prime is generated, the upper two octets for prime candidates are verified to be B5 05_{16} or greater. This forces the prime to be greater than 0.7071075439453125 * $2^{(n/2)}$ where n is the number of bits in the public modulus. This is slightly larger than the required value of $\sqrt{2}/2$ * $2^{(n/2)}$. This value ensures that the MSb of the product of these to prime will be SET. Setting of the two most significant bits would also ensure that the magnitude of the product is large enough but reduced the range of allowed primes by small factor (about 4.3%).

c) test p to determine if it is probably prime

   1) Using a greatest common divisor ($\mathbf{GCD}$()) function, see if p shares any common factors with a composite number that is the product of the first 1024 primes and if so, go to a).

   2) do N rounds of Miller-Rabin where N is determined by the size of the prime and if the test fails on any round, go to a)

      NOTE 4 The value for N may be found in FIPS 186-3, Table C.2.

NOTE 5 The witness values used by Miller-Rabin are from the same random number function used to generate the prime candidate.

d) return p

B.8.3 RSA Key Generation Algorithm

The key generation process is:

a) initialize the values of the algorithm

1) Set $securityStrength$ according to the size of the public modulus of the key to be generated as specified in SP800-57 part 1.

2) $primeSize$ ≔ 1/2 the size of the RSA modulus (*inPublic.parameters.keyBits* of the template)

b) find a first prime (p) using the method in B.8.2

c) find a second prime (q) using the method in B.8.2:

d) If $|p - q| < 2^{100}$, go to b)

e) compute the public modulus $n \coloneqq p \bullet q$

NOTE 1 Depending on the starting values the algorithm could take many iterations to find two suitable primes.

f) compute the private exponent $d \coloneqq e^{-1}$ (mod $(p - 1)(q - 1)$)

NOTE 2 The reference implementation also provides an option to use the CRT form of the private exponent d.

g) if $d < 2^{nLen/2}$ where $nLen$ is the number of bits in the public modulus (n), then go to step b)

NOTE 3 If required, a random value is encrypted with the public exponent and decrypted with the private exponent to validate that the key can be used for signing and signature verification.

h) return n, p and d

B.9 RSA Cryptographic Primitives

B.9.1 Introduction

When RSA is implemented on a TPM, it may provide these additional commands to support cryptographic operations. The command description in TPM 2.0 Part 3 indicates the restrictions on the types of keys that may be used with each of the commands.

B.9.2 TPM2_RSA_Encrypt()

TPM2_RSA_Encrypt() may be used to perform encryption according to the methods described in IETF RFC 8017. If the scheme of the key is TPM_ALG_NULL, then the encryption scheme may be specified in the command. Otherwise, the scheme specified in the key will be used. The scheme options are:

- TPM_ALG_NULL – selects RSAEP as described in B.2
- TPM_ALG_OAEP – selects RSAES_OAEP as described in B.4

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

B.9.3 TPM2_RSA_Decrypt()

TPM2_RSA_Decrypt() performs the decryption operations defined in IETF RFC 8017, clause 7.1.2. The handle used in this command is required to have the *decrypt* attribute SET. If the scheme of the key is TPM_ALG_NULL, then the encryption scheme may be specified in the command. Otherwise, the scheme specified in the key will be used. The scheme options are:

- **TPM_ALG_NULL** – selects RSADP as described in B.3
- **TPM_ALG_OAEP** – selects RSAES_OAEP as described in B.4
- **TPM_ALG_RSAES** – selects RSAES_PKCSV1_5 as described in B.5

B.10 Secret Sharing

B.10.1 Overview

When data is to be delivered securely to the TPM a secret sharing mechanism is required. There are three cases when RSA is used for secret sharing:

1) injecting a salt value for an authorization session,
2) exchanging protection values for object duplication, and
3) exchanging protection values for identity credentials.

For each of these uses, a secret value is OAEP encrypted as described in B.4.

The size of the secret value is limited to the size of the digest produced by the *scheme* hash algorithm (or *nameAlg* if the scheme hash algorithm is TPM_ALG_NULL) of the object that is associated with the public key used for OAEP encryption.

B.10.2 RSA Encryption of Salt

In TPM2_StartAuthSession(), when *tpmKey* is an RSA key, the secret value (*salt*) is encrypted using OAEP as described in B.4. The string “SECRET” (see 4.5) is used as the *L*. The data value in OAEP-encrypted blob (*salt*) is used to compute *sessionKey*.

B.10.3 RSA Secret Sharing for Duplication

When the new parent for a duplicated object is an RSA key, a random seed value is created and used in the KDF operations to generate a symmetric encryption key and IV according to equation (33) and an HMAC key according to equation (35). The seed value will be OAEP encrypted to the public key of the new parent as described in B.4 using “DUPLICATE” as the L parameter. The seed size will be the size of a digest produced by the OAEP hash algorithm of the new parent.

On TPM2_Import() the private key of the new parent is used to decrypt the key protector containing the seed value. If the label value in the OAEP encrypted blob is not “DUPLICATE”, then the decryption routine should generate an error. The error should cause the seed value to be set to an invalid value so that the error will not be reported until the integrity HMAC is validated.

NOTE This is to ensure consistency in behavior with ECC and to minimize the information available to an attacker.

B.10.4 RSA Secret Sharing for Credentials

When a credential is protected (such as TPM2_MakeCredential() and TPM2_ActivateCredential()), a random seed value is created and used as described in B.10.3. The only difference is that the label value used for the KDF will be “IDENTITY” instead of “DUPLICATE”

Annex C
(normative/informative)
ECC

C.1 Introduction

The ECC algorithm is used for digital signatures and for secret sharing.

NOTE 1 As implemented in a TPM, ECC is not used directly for encryption of data. Rather, ECDH secret sharing is used to establish a symmetric key, and then a symmetric algorithm is used for the actual data encryption.

A TPM should support prime modulus ECC.

If the ECC algorithm is supported, the TPM is required to support ECDSA and ECDH (SP800-56A, Clause 6.2.2.2 "One-Pass Diffie-Hellman, C(1, 1, ECC CDH)").

The TPM should support ECC key sizes of at least 256 bits. Support for other key sizes is allowed.

NOTE 2 It is anticipated that the recommended ECC key size will increase over time in revisions to this specification.

The TPM does not check the security of ECC curve parameters. It does check that the public and private keys are properly paired.

NOTE 3 Validating the pairing of the key's public and private portions need not be performed when the key is being loaded. However, this check is required to be performed before the authorization value of the key or the private portion of the asymmetric key may be used.

C.2 Split Operations

C.2.1 Introduction

Several of the EC schemes us two-phase protocols in which the TPM generates an ephemeral key pair in the first phase and uses that ephemeral key in the second phase. These protocols require that the ephemeral key only be used once. Ordinary TPM keys have context that may be saved and restored by TPM context management. This clause describes the methods used to implement the required single use ephemeral keys.

C.2.2 Commit Random Value

A split operation requires two TPM commands the first of which is TPM2_Commit(). It uses a TPM-generated, random value in the commit computation. A second command (such as, any of the signing commands) completes the split signing operation and uses the same commit value. The random commit value is required to:

- have at least the number of bits equal to the security strength of the signing key;
  - not be known outside of the TPM; and
  - only be used once.

Because the random value is not allowed to be known outside of the TPM, the TPM is required to store the random value between the two commands in split sequence. To allow more than one split sequence to be in process at a time, the TPM may have an array of values and return a count value as one of the

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

response parameters of the TPM2_Commit() indicating the array entry being used for the sequence. This count value is an input to the TPM in the command that completes the split sequence.

NOTE The number of split sequences supported by the TPM may be found using TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTIES, *property* = TPM_PT_SPLIT_MAX).

To minimize the size of the array used for storing these values, a TPM may generate pseudo-random values instead.

If using pseudo-random values, the TPM creates the value using **KDFa**(), a counter (*commitCount*), and a random value (*commitRandom*). On each TPM Reset, the TPM will select a new random value for *commitRandom* and reset *commitCount* to zero. On TPM2_Commit(), the TPM would use the current value of the *commitCounter* to generate the pseudo-random value (*r*) by

$$r \coloneqq \mathbf{KDFa}\ (vendorAlg, commitRandom, \text{“ECDAA Commit”}, name, commitCount, bits) \tag{62}$$

where

$nameAlg$	the *nameAlg* of the signing key (*signHandle*)
$commitRandom$	the current value of *commitRandom*
“ECDAA Commit”	value used to differentiate uses of **KDFa**()
$name$	the Name of *signHandle*
$commitCount$	the current value of *commitCount*
$bits$	the number of bits in the order of the curve of the signing key (*signHandle*) NOTE: When the number of bits is not a multiple of 8, it is rounded up to be a multiple of 8.

To track the usage of the *commitCount*, the TPM maintains a bit array (*A*[]) that has a power of 2 number of bits (*N*) (that is, the bits indexes of *A*[] are from 0 to 2^N-1). After computing the value of *r*, the low-order *N* bits of *commitCount* are used to index *A*[] and the corresponding bit is SET. The low-order 16 bits of *commitCount* are returned as the *counter* parameter.

C.2.3 TPM2_Commit()

TPM2_Commit() performs the first part of a split operation. The TPM will perform the point multiplications on the provided points and return intermediate signing values. Alternatively, the TPM will simply return a public ephemeral key based on a commit private value. The *signHandle* parameter refers to an ECC key. TPM2_Commit() has the following parameters, all of which are optional.

$P1$	point on the curve used by *signHandle* (a TPM2B_ECC_POINT)
$s2$	octet array used to derive x-coordinate of a base point (a TPM2B_ECC_PARAMETER)
$y2$	y-coordinate of the point associated with *s2* (a TPM2B_ECC_PARAMETER)

NOTE 1 *P1* is a TPM2B_ECC_POINT, a sized buffer containing a TPMS_ECC_POINT. It is not a sized buffer containing an array of bytes. A size of zero for the TPM2B_ECC_POINT will create an unmarshaling error because the minimum size for *P1* is 4 (two ECC parameters, both of which are Empty Buffers). If *P1* is an Empty Buffer, the TPM returns TPM_RC_INSUFFICIENT regardless of *s2* and *y2*. If *P1* is an Empty Point and *s2* and *y2* are Empty Buffers, then the TPM will set E := [r]G where r is the commit random value and G is the generator point for the curve.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

In the algorithm below, the following additional values are used in addition to the command parameters:

$\mathbf{H}_{nameAlg}$	hash function using the *nameAlg* of the key associated with *signHandle*
p	field modulus of the curve associated with *signHandle*
n	order of the curve associated with *signHandle*
d_s	private key associated with *signHandle*
G	generator of the curve associated with *signHandle*
c	counter that increments each time TPM2_Commit() is executed
$A[i]$	array of bits used to indicate when a value of *c* has been used in a signing operation; the values of *i* are 0 to 2*N*-1.
N	log2 of the number of values in *A*
k	nonce that is set to a random value each on each TPM Reset; the nonce size is twice the security strength of any ECDAA key supported by the TPM

The commit algorithm is:

a) Validate that *s2* and *y2* are either both Empty Buffers or both not Empty Buffers (TPM_RC_SIZE)

b) If s2 is an Empty Buffer, skip to step e)

c) compute $x2 \coloneqq \mathbf{H}_{nameAlg}(s2) \bmod p$

d) if $(x2, y2)$ is not a point on the curve of *signHandle,* return TPM_RC_ECC_POINT

e) if $p1$ is not an Empty Point and *p1* is not a point on the curve of *signHandle,* return TPM_RC_ECC_POINT

f) set K, L, and E to be Empty Buffers

g) generate or derive *r* (see C.2.2)

h) set $r \coloneqq r \bmod n$

i) if *s2* is not an Empty Buffer, set $K \coloneqq [d_s]\,(x2, y2)$ and $L \coloneqq [r]\,(x2, y2)$

j) if *p1* is not an Empty Point, set $E \coloneqq [r]\,(p1)$

k) if $p1$ is an Empty Point and *s2* is an Empty Buffer, set $E \coloneqq [r]\,G$

l) if K, L, or E is the point at infinity, return TPM_RC_NO_RESULT

m) set $counter \coloneqq commitCount$

n) set $commitCount \coloneqq commitCount + 1$

NOTE 2 Depending on the method of generating *r*, it may be necessary to update the tracking array here.

o) output K, L, E and $counter$

NOTE 3 Depending on the input parameters, K and L or E may be Empty Points

C.2.4 TPM2_EC_Ephemeral()

TPM2_EC_Ephemeral() is similar to TPM2_Commit() in that it uses the commit random value to generate an ephemeral key for use in a two-phase operation. However, TPM2_EC_Ephemeral() only used the

 Copyright © TCG 2006-2020

random value r to generate a corresponding public key $Q \coloneqq [r]G$ where G is the generator point for a specified curve.

As with TPM2_Commit(), a counter value is returned. This value needs to be used in a subsequent command in order to complete the two-phase operation.

C.2.5 Recovering the Private Ephemeral Key

To complete a split or two-phase operation, the TPM uses the same random or pseudo-random value generated in TPM2_Commit(). The random or pseudo-random value is determined by the *counter* field provided as an input parameter for the command that is the second phase of the split operation.

If the values are stored in an array, *counter* is used to index the array and, after the value is used in the signing operation, the value is erased. If using the pseudo-random method, the following algorithm is used to reconstruct the random value.

a) set $t \coloneqq$ low-order 16 bits of $commitCount$

b) verify that $t - 2^N < counter < t$; else return TPM_RC_RANGE

c) set $i \coloneqq$ low-order N bits of $counter$

d) if $A[i]$ is CLEAR, return TPM_RC_VALUE

e) set $c \coloneqq commitCount - t$

f) if $counter \geq t$; $c \coloneqq c - 2^{16}$

g) $c \coloneqq c + counter$

h) compute r as in equation (62) using c in place of $commitCount$

i) if the command completes successfully set $A[i] \coloneqq 0$

C.3 ECC-Based Secret Sharing

An ECC key protects a secret in two cases: object duplication and seeding of a session. In both cases, the method for generating the required key uses **KDFe**(), as described in 11.4.10.3.

C.4 EC Signing

C.4.1 ECDSA

For a TPM compliant with this specification, the default ECC signing scheme (DSA) is as defined ISO/IEC 14888-3.

C.4.2 ECDAA

C.4.2.1 Introduction

If a TPM supports ECC, it is recommended that it also support the ECDAA scheme described in this clause C.4.2.

Direct Anonymous Attestation based on ECC (ECDAA) is a TPM signature scheme that provides anonymous signatures (meaning that different signatures from the same signer cannot be correlated), or pseudonymous signatures (meaning that different signatures from the same signer can be correlated but

 Copyright © TCG 2006-2020

the identity of the signer is still unknown). Multiple ECDAA schemes are supported in this TPM implementation.

The TPM signs data with an ECDAA key in an unconventional way. A Verifier verifies signature values using data equivalent to a public key, and verifies the public key using data equivalent to a certificate (which is also called a credential) supplied by an Issuer. However, the public key and the credential are randomized by the TPM and the TPM's Host platform before they are sent to the Verifier. This prevents both the Verifier and the Issuer from identifying the TPM that created the signature value.

It is anticipated that the most common use of ECDAA will be to certify (TPM2_Certify()) a TPM object (usually a key). A credential issuer will provide a certificate for an ECDAA key. This certificate will validate that the ECDAA key belongs to a valid TPM without disclosing the ECDAA key. That ECDAA key may then be used to certify other TPM objects. These certificates prove that the certified object belongs to a valid TPM without disclosing the identity of that TPM. If the certified key is a signing key, it may then be used to attest to various TPM states, without disclosing the identity of the TPM to which it belongs.

This scheme is substantially different from the AIK scheme in 1.2 in that the ECDAA key may be used to provide the anonymity for keys rather than having to send each new attestation key to a privacy certificate authority (PCA) in order to have an anonymizing certificate produced. After a certificate has been obtained for an ECDAA key, it may be used to produce anonymized certificates for many TPM keys without requiring additional interaction with a privacy CA.

An ECDAA key may be used in any command that produces a signature. The TPM may not be used to verify an ECDAA signature.

C.4.2.2 ECDAA Key Generation on the TPM

While any signing key may be an ECDAA key, it is most useful as a Primary Key in the Endorsement hierarchy. This ensures that a TPM will normally produce the same ECDAA keys and receive the same credentials from a given Issuer, no matter how many times the credentialing process is performed, and no matter how many owners the TPM has had. This property is desirable because an Issuer should only give credentials to a platform after verifying that the platform has the architecture of a trusted platform. The Issuer would give replacement (different) credentials only when it is necessary to retire the old credentials. Replacement credentials erase the previous DAA history of the platform, at least as far as the credentials from that issuer are concerned. Replacement might be desirable, as when a platform changes hands, for example, in order to eliminate any association via DAA between the seller and the buyer. On the other hand, replacement might be undesirable, since it enables a rogue to rejoin a community from which it has been barred. Replacement is done by submitting a different TPMT_PUBLIC.*unique* field value to the TPM when the key is created (TPM2_Create() or TPM2_CreatePrimary()). Software may use any value of TPMT_PUBLIC.*unique* field at any time, in any order, but the Issuer can detect when a request uses a different value from the previous request and could reject the request.

The cryptographic parameters of the curve are indicated by the template in the command (TPM2_Create() or TPM2_CreatePrimary()) that creates the curve. The curve ID depends on the Issuer who is expected to provide a credential for the DAA key (different Issuers may require different curves). The TPM generates a private key (d_s) and a public key (Q_s). The non-cryptographic parameters in the template (that is, object attributes and signing scheme) are chosen by the entity that calls the command to create the DAA key. Inappropriate choice of the non-cryptographic parameters will cause the Issuer to reject an application for a DAA credential.

The security strength of an ECDAA key is the same as an ECC key of the same size. The key size is determined by the order of the curve (n) and the cofactor (h).

If the Endorsement Primary Seed is used as the DAA seed, then, like other EK, an ECDAA key will change whenever the EPS is changed.

 Copyright © TCG 2006-2020

The process for generating an ECDAA key is identical to the process used for any ECC key.

For the TCG defined ECDAA protocol, the curve described by p, n, and b is a Barreto-Naehrig (BN) elliptic curve. BN curves are of the form $y^2=x^3+b$ as defined in [ISO/IEC 15946-5 : 2008 Clause 7.3 “BN curve”], which is equivalent to [IEEE P1363.3 (Draft 2) Clause A.11.5 BN Curves].

NOTE The linear term (a) of generic ECC curves (curves with the form $y^2=x^3+ax+b$) is zero in BN curves. All BN curves are suitable but some are less efficient than others. The BN curves recommended in this version of DAA were chosen by the DAA designers.

The cryptographic value of the public key in the resultant TPM key structure is Q_s, which is used by the Issuer when computing the membership credential on the DAA private key d_s. Q_s is not used to verify the DAA signatures produced by the TPM and corresponding host platform.

C.4.2.3 ECDAA Sign Operation

The ECDAA scheme may be used in any command that uses a signing key. These are, the attestation group and TPM2_Sign().

For an attestation command using the ECDAA scheme, both the *qualifiedSigner* and *extraData* fields in the attestation block (a TPMS_ATTEST) are set to be the Empty Buffer before the data is hashed. The attestation data is then marshaled and hashed. The resulting hash data is then concatenated to the first hash to produce the value to sign (P).

$$P \coloneqq \mathbf{H}_{schemeHash}(qualifyingData \mid\mid \mathbf{H}_{schemeHash}(\text{TPMS_ATTEST})) \quad (63)$$

For TPM2_Sign(), the value to sign is the input *digest* and

$$P \coloneqq digest \quad (64)$$

To complete the ECDAA sign operation, the TPM uses the same random or pseudo-random value (r) used in TPM2_Commit(). The value is determined by the *counter* field in the scheme parameter of the signing command. This parameter is used in the process defined inC.2.5.

The signature is created using a modified Schnorr signature using the P and r values described above:

a) set k to a random value such that $0 < k < n$

b) compute $T \coloneqq \mathbf{H}(k \mid\mid P)(\text{mod } n)$

c) compute integer $s \coloneqq (r + Td_s)(\text{mod } n)$

d) if $s = 0$, output failure (negligible probability)

The signature is the tuple (k , s).

NOTE The k value is returned in the *R* parameter of the TPMT_SIGNATURE structure.

C.4.3 EC Schnorr

C.4.3.1 Introduction

If a TPM supports ECC, it should support the TPM_ALG_ECSCHNORR scheme.

The scheme description uses the following values:

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

G	generator point for the curve of the signing key
d_S	private value of the signing key
Q_S	public point of the signing key ($Q_S \coloneqq [d_S]G$)
n	order of G
$\mathbf{H}_{schemeHash}$	hash algorithm specified in the signing scheme

C.4.3.2 EC Schnorr Sign

An EC Schnorr signature is generated when the signing scheme for a key is TPM_ALG_ECSCHNORR. The scheme many be used in any signing operation

To sign a digest P

a) set k to a random value such that 0 < k < n

b) compute $E \coloneqq (x_E, y_E) \coloneqq [k]G$

c) if E is the point at infinity, go to a)

d) compute $r \coloneqq \mathbf{TRUNC}(\mathbf{H}_{schemeHash}(\mathbf{FE2BS}(x_E) \mid\mid P), n)$

NOTE 1 x_E is a field element with the same number of bits as the curve order n

NOTE 2 **TRUNC**() is a function that reduces the number of octets in the first argument until it has no more octets than the second argument. Truncation occurs from the less significant end of the number. If the digest produced by $\mathbf{H}_{schemeHash}$ has the same number of octets as the curve order n, then no truncation occurs.

NOTE 3 **FE2BS**() is a function that converts the number x_E (a field element) into a canonical value (octet or byte string) with the same number of octets as the field order n. This may result in a value with leading octets of zero. As x_E is computed (mod p) the value may be greater than n

e) compute integer $s \coloneqq (k + rd_S) \pmod{n}$

NOTE 4 This is the same computation as step c) in C.4.2.3.

f) if $s = 0$ or $s = k$ go to a)

NOTE 5 The $s = k$ check is to eliminate the possibility that $0 = r \pmod{n}$. Optionally, an implementation could check after d) that $0 \neq r \pmod{n}$.

The signature is the tuple (r, s).

C.4.3.3 EC Schnorr Signature Validate

To validate a Schnorr signature (r, s) over digest P

a) verify that 0 < s < n

b) compute $(x_E, y_E) \coloneqq [s]G + [-r]Q_S$

c) compute $r' \coloneqq \mathbf{TRUNC}(\mathbf{H}_{schemeHash}(\mathbf{FE2BS}(x_E) \mid\mid P), n)$

d) the signature is valid if $r' = r$

 Copyright © TCG 2006-2020

NOTE The comparison of r' and r is done assuming that both values are numeric and not octet strings. This reduces the chance of interoperability problems due to padding performed on r.

C.5 ECC Key Generation

For an ECC key, the method of FIPS 186-4, Annex B.4.1 *Key Pair Generation Using Extra Random* is used. The caller provides a random number generation function according to the type of key being generated (see 27.6.2, 27.6.3, and 28.4) and that function is called when random bits are required by the generation process. The key generation process is:

a) obtain a random value c of $\mathbf{length}(n)$ + 64 bits where n is the order of the curve
b) set $d \coloneqq (c \bmod (n\text{-}1)) + 1$
c) compute $Q \coloneqq (x_Q, y_Q) \coloneqq [d]G$
d) return d and Q

C.6 Secret Sharing

C.6.1 ECDH

For secret sharing with an ECC key, the One-Pass Diffie-Hellman, C(1, 1, ECC CDH) method from SP800-56A is used.

Using the notation of SP800-56A, the initiator generates an ephemeral key pair ($d_{e,U}$, $Q_{e,U}$) from the curve parameters. The public point of the ephemeral key($Q_{e,U}$) is used by the recipient to recover the shared secret.

The initiator uses the private portion of the ephemeral key ($d_{e,U}$) and the public portion ($Q_{s,V}$) of an ECC key of the recipient and computes the point $P \coloneqq h\ [d_{e,U}]Q_{s,V}$. Then it will set $Z \coloneqq x_P$ where x_P is the x-coordinate of P.

The recipient may compute $P \coloneqq h\ [d_{s,V}]Q_{e,U}$ and $Z \coloneqq x_P$.

The Z value is used in ***KDFe*** to generate a value for *seed* that is appropriate for the use of the seed. The seed will be the size of the digest produced by the *hashAlg* used in the KDF. Seed is computed by:

$$seed \coloneqq \mathbf{KDFe}(hashAlg, Z, label, PartyUInfo, PartyVInfo, bits) \quad (65)$$

where

$hashAlg$	the nameAlg of the recipient key
Z	the x coordinate (x_P) of the product (P) of a public point and a private key (P ≔ h [d] Q)
$label$	an application-dependent value
$PartyUInfo$	the x-coordinate of the secret exchange value ($Q_{e,U}$)
$PartyVInfo$	the x-coordinate of a public key ($Q_{s,V}$)
$bits$	the number of bits in the digest of hashAlg

 Copyright © TCG 2006-2020

C.6.2 ECDH Encryption of Salt

In TPM2_StartAuthSession(), when *tpmKey* is an ECC key, a seed value is produced as described in C.6.1 with the *label* parameter set to "SECRET". This seed value is then used as the session secret.

C.6.3 ECC Secret Sharing for Duplication

When the new parent for a duplicated object is an ECC key, an ephemeral key is created and used to generate a seed value as described in C.6.1. When creating the seed, the label parameter is set to "DUPLICATE". The seed value is then used to generate the encryption and integrity values for the duplication blob as described in clause 22.

C.6.4 ECC Secret Sharing for Credentials

When the decryption key for an identity blob is an ECC key, an ephemeral key is created and used to generate a seed value as described in C.6.1. When creating the seed, the label parameter is set to "IDENTITY". The seed value is then used to generate the encryption and integrity values for the identity blob as described in clause 22.

C.7 ECC Primitive Operations

C.7.1 Introduction

When ECC is implemented on a TPM, it may provide these additional commands to support cryptographic operations with unrestricted ECC keys.

C.7.2 TPM2_ECDH_KeyGen()

TPM2_ECDH_KeyGen produces an ephemeral key pair. It multiplies the private ephemeral key with the public point of a loaded TPM key to produce the Diffie-Hellman shared secret.

This function can be performed by software as the public key and parameters are known. The function would be provided by the TPM as a service.

Since the operation can be performed by software, no authorization is required to use the public portion of the key and the key attributes are not checked.

C.7.3 TPM2_ECDH_ZGen()

TPM2_ECDH_ZGen performs the ECDH primitive function with one static and one ephemeral key as defined in SP800-56A, clause 6.2.2. The input point (Q_e) is multiplied by the private coordinate (d_s) to produce the point $Z = (x_Z, y_Z) \coloneqq hd_sQ_e$.

Since this operation used the private portion of an ECC key, authorization is required. To prevent inadvertent compromise of a signing key, *sign* and restricted are required to be CLEAR in the referenced key.

 Copyright © TCG 2006-2020

C.7.4 Two-phase Key Exchange

C.7.4.1 Introduction

Various key exchange protocols use an ephemeral key from each party. For these protocols, each party generates an ephemeral key and that key is sent to the other party along with other information. The other party then uses the key material from the other party along with its own ephemeral key to generate the key-exchange values.

These protocols require two phases. In the first phase, the TPM generates an ephemeral key to be sent to the other party. In the second phase, the TPM combines data from the other party with the ephemeral key generated in the first phase. The protocols require that the ephemeral key generated by the TPM only be used once and be discarded after the key exchange is complete. This property of this key is the same as required for ECDAA.

TPM2_EC_Ephemeral() uses the commit mechanism to generate a random value (r) and a public key $P \coloneqq [r]G$. The value of P is returned to the caller along with the counter value associated with r.

TPM2_ZGen_2Phase() is used to complete the second phase of the key exchange. The counter value returned by TPM2_EC_Ephemeral() is provided from which the TPM recreates r and regenerates the associated public key. When TPM2_ZGen_2Phase() completes successfully, the TPM will "retire" the r value so that it may not be used again.

One of the parameters of TPM2_ZGen_2Phase() is a scheme selector (*inScheme*). This indicates to the TPM which of the supported schemes is to be used. This annex describes two of the allowed schemes. They are the two EC schemes from SP800-56A that require two ephemeral and two static keys. The schemes are described in SP800-56A in *6.1.1.2 Full Unified Model, C(2, 2, ECC CDH)* and *6.1.1.4 Full MQV, C(2, 2, ECC MQV).* These schemes use the following terms:

$d_{s,A}$	the private part of a TPM-resident ECC key referenced by the *keyA* parameter
$Q_{s,A}$	the public point of the key referenced by *keyA* equal to $[d_{s,A}]G$ with coordinates $(x_{s,A}, y_{s,A})$
$d_{e,A}$	a private ephemeral key generated by the TPM (the value of r associated with *counter* parameter)
$Q_{e,A}$	the public ephemeral key associated with *counter* equal to $[d_{e,A}]G$ or $[r]G$ with coordinates $(x_{e,A}, y_{e,A})$
$Q_{s,B}$	the *inQsB* parameter – a point on the curve of *keyA* assumed to be a static public key associated with the other party in the key exchange with coordinates $(x_{s,B}, y_{s,B})$
$Q_{e,B}$	the *inQeB* parameter – a point on the curve of *keyA* assumed to be an ephemeral public key associated with the other party in the key exchange with coordinates $(x_{e,B}, y_{e,B})$

C.7.4.2 Full Unified Model

When this scheme is selected for TPM2_ZGen_2Phase(), the TPM will:

a) set *outZ1* $\coloneqq [d_{s,A}]Q_{s,B}$

b) set *outZ2* $\coloneqq [d_{e,A}]Q_{e,B}$

 Copyright © TCG 2006-2020

NOTE If outZ1 or outZ2 is the point at infinity, then both coordinate values of the point will be Empty Buffers.

C.7.4.3 Full MQV

This scheme uses an associated value function (**avf**()) that is defines as:

Inputs:

$Q = (x, y)$	a public key
n	the modulus of the curve containing Q

Process:

Process:

a) Set $f \coloneqq \lceil(\lceil \log_2(n)\rceil / 2)\rceil$

b) Set $x' = 2^f + (x \bmod 2^f)$

c) return x'

The MQV computation is:

d) validate that $Q_{s,B}$ and $Q_{e,B}$ are on the curve associated with $d_{s,A}$

e) using *counter*, recover $d_{e,A} = r$ as described in C.2.5

f) set $Q_{e,A} \coloneqq [d_{e,A}]G$ where G is the generator point for the curve of $d_{s,A}$

g) set $t_A \coloneqq (d_{e,A} + d_{s,A} \cdot \mathbf{avf}(Q_{e,A}))$ (mod n)

h) set *outZ1* $\coloneqq [h \cdot t_A]\,(Q_{e,B} + [\mathbf{avf}(Q_{e,B})](Q_{s,B}))$

NOTE 1 if *outZ1* is the point at infinity both the coordinate values of outZ1 will be Empty Buffers

NOTE 2 This protocol may be susceptible to unknown key-share (UKS) attacks.

C.8 ECC Point Padding

To provide consistent behavior across all TPM implementations this clause specifies the padding requirements for ECC parameters. An ECC point returned by the TPM is composed of x and y ECC parameters, both of which are required to be the size of their associated curve (e.g., 32 bytes for NIST P-256). If necessary, leading bytes of zero will be added to these point values. When the ECC parameters are returned by the command TPM2_ECC_Parameters(), the numeric values will be as specified in the TCG Algorithm registry. However, the size of values, other than the *x* and *y* of the generator point, may not be the same as the registry because values may or may not be zero padded.

To ensure interoperability, an ECC point that is part of a TPM2B_PUBLIC should be padded with zeros to be the size of the order of the curve that defines the key.

When an ECC point is input to the TPM, the padding is required as described above for TPM output of an ECC point.

NOTE: The reason for requiring padding on the input of an ECC point is that an ECC point makes up the *unique* field of an ECC key. The Name of the key is computed by hashing the key's public area as input to the TPM. If the ECC point in the *unique* field is not properly padded, the Name would not be consistent.

 Copyright © TCG 2006-2020

An intermediate ECC point, such as the result of an ECC point multiplication or the public key of an ephemeral ECC key, is required to be padded if used as input to the KDFe() function.

NOTE This ensures that the secret derived from KDFe(), which is used e.g. as salt in TPM2_StartAuthSession(), or as protection seed of the outer wrapper in TPM2_Duplicate(), is the same on different implementations.

Revision 1.16 of this specification also required the ECC private key in *duplicate* of TPM2_Import() to be padded.

Annex D
(normative/informative)
Support for SMx Family of Algorithms

D.1 Introduction

This section provides additional information for implementation of the SM2, SM3, and SM4 algorithms published by State Encryption Management Bureau, China.

D.2 SM2

D.2.1 Introduction

SM2 is contains information relating to ECC cryptography and is in five parts.

- Part 1: General – "provides necessary basics of mathematics and related cryptographic techniques used in public key cryptographic algorithm SM2 based on elliptic curves." The methods of this part are compatible with the EC methods in other standards and no special considerations are necessary to accommodate this standard

[GM/T 0003.1-2012 *Public Key Cryptographic Algorithm SM2 Based on Elliptic Curves, part1: General Protocol*, published by State Encryption Management Bureau, China]

- Part 2: *Digital Signature Algorithm* – defines the process for generation and verification of a digital signature using the methods described in Part 1. The signing method in this part of the standard require addition of a new signing scheme and methods. These are described in this annex. .

[GM/T 0003.2-2012 *Public Key Cryptographic Algorithm SM2 Based on Elliptic Curves, part2: Digital Signature Algorithm*, published by State Encryption Management Bureau, China]

- Part 3: *Key Exchange Protocol* – defines a two phase key exchange protocol using the methods of Part 1. The method in this part of the SM2 standard is supported by addition of a key exchange command (TPM2_ZGen_2Phase()). The algorithm is fully described in TPM 2.0 Part 3 of this TPM specification.

[GM/T 0003.3-2012 *Public Key Cryptographic Algorithm SM2 Based on Elliptic Curves, part3: Key Exchange Protocol*, published by State Encryption Management Bureau, China]

- Part 4: Public Key Encryption Algorithm – defines an encryption method using single pass EC Diffie-Hellman to exchange a key that is then used to generate a stream cipher. The TPM does not use this method.

[GM/T 0003.4-2012 *Public Key Cryptographic Algorithm SM2 Based on Elliptic Curves, part4: Public Key Encryption Algorithm*, published by State Encryption Management Bureau, China.]

- Part5: Parameter definition – defines the parameters for a 256-bit ECC curve.

[GM/T 0003.5-2012 *Public Key Cryptographic Algorithm SM2 Based on Elliptic Curves, part5: Parameter definition*, published by State Encryption Management Bureau, China]

 Copyright © TCG 2006-2020

D.2.2 SM2 Digital Signature Algorithm

D.2.2.1 SM2 Sign

The SM2 signing scheme has an algorithm ID of TPM_ALG_SM2. If the TPM implements this algorithm, then any structure that allows an ECC-based signing scheme may use this algorithm ID.

The TPM only implements a portion of the full SM2 signing scheme. That portion is the part that uses the private key to sign a digest.

The inputs to the algorithm are:

e	a digest to sign
d_s	a private ECC key
n	the modulus of the curve for d_s

The computation implemented in the TPM is:

a) set k to a random value such that $1 \leq k \leq n$-1

b) compute $P_1 \coloneqq (x_1, y_1) \coloneqq [k]G$

c) compute $r \coloneqq e + x_1$ (mod n)

d) if r equals 0 or ($r + k$) equals n, go to 0

e) compute $s \coloneqq ((1 + d_s)^{-1} \cdot (k - r \cdot d_s))$ (mod n)

f) if s equals 0, go to 0

g) the signature is the tuple (r, s)

D.2.2.2 SM2 Signature Verification

For verification (TPM2_VerifySignature() and TPM2_PolicySigned()), the inputs are:

e	the digest that was signed
(r, s)	the signature tuple
P	a public ECC key
G	the generator point for the curve of P
n	the modulus of the curve for d_s

a) The verification computation performed by the TPM is:

b) verify that r and s are in the inclusive interval 1 to (n – 1)

c) compute $t \coloneqq (r + s)$ (mod n)

d) verify that $0 < t$

e) compute $(x, y) \coloneqq [s]G + [t]P$

f) compute $r' \coloneqq (e + x)$ (mod n)

g) verify that $r' = r$

If any of the verification steps fails, then the signature is not valid.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

D.2.2.3 Implementation Issues

In the SM2 standard, the message to sign is combined with key-specific data to produce an e value that is signed using the algorithm shown above. The computation for e uses a value Z_A that, according to the SM2 standard, is computed by:

$$Z_A \coloneqq \mathbf{H}(\ ENTL_A \,||\, ID_A \,||\, a \,||\, b \,||\, x_G \,||\, y_G \,||\, x_A \,||\, y_A\ ) \tag{66}$$

where

$ENTL_A$	two octets containing the length of ID_A in octets
ID_A	octet string containing information that can identify an entity's identity unambiguously (see ISO/IEC 15946-3 3.9)
a	coefficient for the linear term of the equation for the curve of the signing key
b	coefficient for the constant term of the equation for the curve of the signing key
x_G	the x coordinate of the generator point for the curve of the signing key
y_G	the x coordinate of the generator point for the curve of the signing key
x_A	the x coordinate of the public key of the signing key
y_A	the y coordinate of the public key of the signing key

Using Z_A and a message (M) the digest to sign (e) is computed by:

$$e \coloneqq \mathbf{H}(Z_A \,||\, M) \tag{67}$$

Since the TPM does not do the operation in equation (67), the caller may need to modify the input message before using the TPM to sign the digest. If the application requires it, the caller would need to do the computation of e before giving the value to the TPM to sign.

One consequence of this is that attestation operations will not create a signature that is in all details, compliant with SM2 Part 2. Instead, the attestation signatures will be TPM specific. The reason that attestations do not sign using the full scheme are:

- There is no infrastructure for the distribution of ID_A values
- Requiring the use of an ID_A value in a signature could allow correlation of a user and void the privacy assurances of the attestation
- Ensuring that an external digest does not match a valid attestation becomes intractable.

The reason that the attestation problem becomes intractable is that, using Z_A with an attestation means that the first bytes that were used to form the digest of the signed value (e) would vary with each key used to sign. An attacker could perform a hash using the key specific values followed by message data that has all the characteristics of an attestation. The TPM will not be able to discern the transition from Z_A data to the false attestation data.

To prevent this kind of attack without adding excessive complexity to the TPM, the attestation is done without including Z_A. Since the use of Z_A does not improve the security of the SM2 signature, leaving it out does not compromise the value of the SM2 signing process for attestations. Also, since an attestation only has meaning in the context of a TPM, having TPM-specific verification of a signature over an attestation block should not create an issue.

 Copyright © TCG 2006-2020

TPM2_Sign() may be used with the TPM_ALG_SM2 scheme identifier to create a full SM2-compatible signature. To do an SM2 signature, the application would compute Z_A, and then use the resulting digest as the first data in one of the TPM hash commands (which could be a TPM2_HashSequenceStart()); with the Z_A value followed by the message data (M). The digest of $\mathbf{H}(Z_A \| M)$ would then be used as the *digest* parameter for TPM2_Sign().

NOTE Since Z_A is a constant value for a key, an application might choose to keep Z_A as part of the meta-data for the key so that it would not need to be recomputed each time the key is used for an SM2 signature.

D.2.3 SM2 Key Exchange

D.2.3.1 Introduction

The key exchange algorithm in GM/T 0003.3-2012 is a two-phase algorithm. It is similar to the scheme described in C.7.4.3.

NOTE This protocol may be susceptible to unknown key-share (UKS) attacks.

This SM2 key exchange computations use an associated value function (**avfSM2**()) that is similar to the function defined in SP800-56A with the only differencing being that the result is one bit less than the value defined in SP800-56A. The **avfSM2**() function is:

Inputs:

$Q = (x, y)$	a public key
n	the modulus of the curve containing Q

Process:

a) set $f := \lceil (\lceil \log_2(n) \rceil / 2) \rceil - 1$

b) set $x' := 2^f + (x \pmod{2^f})$

c) return x'

NOTE This function is similar to the function in SP800-56A except that, in the formulation in GM/T 0002-2012 as shown in a) above, the value of f is one less than the equivalent in SP800-56A.

D.2.3.2 SM2 Key Exchange Protocol

The key exchange protocol is between two entities, A and B. The TPM performs computations as party A. Since the protocol is symmetric, both party A and party B may be TPMs and they will both perform the same operations, using the values from the other TPM as party B values.

The caller must use TPM2_EC_Ephemeral() to have the TPM generate a single-use ephemeral key. The ephemeral public key is sent to the other party as $Q_{e,B}$.

The inputs to the key exchange computation are:

$counter$	the counter parameter from TPM2_Commit()
$Q_{s,B}$	a public EC key from party B; usually, the public part of a static key
$Q_{e,B}$	a public EC key; usually, the public part of an ephemeral key
$d_{s,A}$	a private EC key (an unrestricted decryption key)

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

The protocol:

a) validate that $Q_{s,B}$ and $Q_{e,B}$ are on the curve associated with $d_{s,A}$
b) using *counter*, recover *r* as described in C.2.5
c) set $Q_{e,A} \coloneqq [r]G$ where G is the generator point for the curve of $d_{s,A}$
d) set $t_A \coloneqq (d_{s,A} + d_{e,A} \cdot \mathbf{avfSM2}(Q_{e,A}))$ (mod n)
e) set $Z \coloneqq [h \cdot t_A]\ (Q_{s,B} + [\mathbf{avfSM2}(Q_{e,B})](Q_{e,B}))$
f) if Z is the point at infinity, return failure

D.3 SM3

[GM/T 0004-2012 *Cryptographic Hash Algorithm SM3*, published by State Encryption Management Bureau, China]

SM3 is a hash algorithm that uses a 512-bit block and produces a digest of 256 bits.

If the TPM implements this algorithm, then the algorithm ID for SM3 (TPM_ALG_SM3_256) may be used in any structure that allows a hash algorithm.

D.4 SM4

[GM/T 0002-2012 *Block Cipher Algorithm SM4*, published by State Encryption Management Bureau, China]

SM4 is a symmetric block cipher with a key and block size of 128 bits.

If the TPM implements this algorithm, then the algorithm ID for SM4 (TPM_ALG_SM4) may be used in any structure that allows a symmetric block cipher.

 Copyright © TCG 2006-2020

Annex E
(normative/informative)
TDES

E.1 TDES Key Parity Generation

A TDES key is generated by getting 24 bytes from the random number generator appropriate for the type of key generation (such as a KDF for a derived key). The 24 bytes are treated as 3, 64-bit values in canonical TPM form (big-endian bytes). The odd parity is then generated for each byte with the parity replacing the least significant bit in each byte to create 3 DES keys. The resulting three DES keys are then validated to make sure that none of them is on the list of prohibited DES key values. If any of the generated key values is prohibited, then the TPM will repeat the key generating process by generating 24 new bytes.

Annex F
(informative)
Library Profile Guide

F.1 Introduction

This annex provides guidance to TPM platform specific work groups when developing platform specific TPM specifications. The platform specific specification must specify these items. It aggregates platform specific information from other parts of this specification.

F.2 Platform Specific Constants

- Constants returned by TPM2_GetCapability with the capability prefix TPM_PT_PS. See Part 2.
- The manufacturer, vendor strings, and firmware version.

F.3 PCR

- Number of PCR.
- The minimum size of a selection structure.
- Number of banks.
- Supported hash algorithms.
- PCR authorization, authorization groups, and locality.
- Which can be reset, under what conditions, and what the reset value is.
- Whether the PCR is preserved on resume.
- Which PCR increment the PCR update counter.
- DRTM and H-CRTM behavior, and PCR values at _TPM2_Init().

F.4 Algorithms

Define algorithms. See the TCG algorithm registry.

- Hash, asymmetric, and symmetric algorithms.
- For elliptic curve, the curves.
- Key sizes.
- Padding modes.
- Endorsement key certificate provisioning, and the NV attributes for the certificates.
- Algorithms and modes for parameter encryption.

F.5 Commands

See Part 2 and note that some commands have prerequisites or are implemented as a set.

- Mandatory, optional, and forbidden commands.
- Whether firmware upgrade is required, and whether the library specification or a vendor specific method is permitted.

 Copyright © TCG 2006-2020

F.6 Buffers

- The minimum for the maximum size of an NV Index.
- The minimum size for the input and output buffers.

F.7 NV Storage

- Specify as much as possible the NV storage capacity. Since NV Indexes has varying meta-data requirements, the value may not be exact.
- The types of NV Indexes supported. This is linked to the supported TPM2_NV commands.
- Whether NV Indexes and persistent keys may or may not come from the same NV memory pool.
- A minimum number of total Indexes, and minimums for certain Index types, such as counters.
- Whether both orderly and non-orderly indexes are supported.
- The minimum number of persistent key slots.

F.8 Sessions and Objects

- The minimum number of loaded and active sessions.
- The minimum number of loaded objects.

F.9 Physical Presence

- If physical presence is implemented, specify the table of commands that require physical presence.

F.10 Dictionary Attack Lockout

- The default value for maxTries and recoveryTime.

F.11 Self Test

- Whether TPM2_SelfTest() can be blocking or non-blocking.

F.12 ACT

- The number of supported ACT instances (usually 0 or 1).
- Trigger event when the ACT times out.
- Whether TPM2_ClockRateAdjust() may affect the ACT rate, and maximum adjustment.
- The ACT behavior if TPM is in a low power state (sleep mode) (typically, ACT must advance).
- Whether the ACT state must be preserved over a power cycle (setting of the *preserveSignaled* attribute).
- Whether clearing or setting the *signaled* attribute must also clear or set the associated trigger event (e.g. when ACT signaling is turned off, or ACT signaling is preserved across TPM Resume).

 Copyright © TCG 2006-2020

- Whether the remaining ACT timeout must be retrievable in TPM Failure Mode.

Trusted Platform Module Library

Part 2: Structures

1 Scope

This part of the *Trusted Platform Module Library* specification contains the definitions of the constants, flags, structure, and union definitions used to communicate with the TPM. Values defined in this document are used by the TPM commands defined in TPM 2.0 Part 3: *Commands* and by the functions in TPM 2.0 Part 4: *Supporting Routines*.

NOTE The structures in this document are the canonical form of the structures on the interface. All structures are "packed" with no octets of padding between structure elements. The TPM-internal form of the structures is dependent on the processor and compiler for the TPM implementation.

2 Terms and definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

4 Notation

4.1 Introduction

The information in this document is formatted so that it may be converted to standard computer-language formats by an automated process. The purpose of this automated process is to minimize the transcription errors that often occur during the conversion process.

For the purposes of this document, the conventions given in TPM 2.0 Part 1 apply.

In addition, the conventions and notations in clause 4 describe the representation of various data so that it is both human readable and amenable to automated processing.

When a table row contains the keyword “reserved” (all lower case) in columns 1 or 2, the tools will not produce any values for the row in the table.

NOTE The unmarshaling code examples are the actual code that would be produced by the automatic code generator used in the construction of the reference code. The actual code contains additional parameter checking that is omitted for clarity of the principle being illustrated. Actual examples of the code are found in TPM 2.0 Part 4.

 Copyright © TCG 2006-2020

4.2 Named Constants

A named constant is a numeric value to which a name has been assigned. In the C language, this is done with a `#define` statement. In this specification, a named constant is defined in a table that has a title that starts with “Definition” and ends with “Constants.”

The table title will indicate the name of the class of constants that are being defined in the table. When applicable, the title will include the data type of the constants in parentheses.

The table in Example 1 names a collection of 16-bit constants and Example 2 shows the C code that might be produced from that table by an automated process.

NOTE A named constant (**#define**) has no data type in C and an enumeration would be a better choice for many of the defined constants. However, the C language does not allow an enumerated type to have a storage type other than **int** so the method of using a combination of **typedef** and **#define** is used.

EXAMPLE 1

Table xx — Definition of (UINT16) COUNTING Constants

Parameter	Value	Description
first	1	decimal value is implicitly the size of the
second	0x0002	hex value will match the number of bits in the constant
third	3	
fourth	0x0004	

EXAMPLE 2

```
/* The C language equivalent of the constants from the table above */
typedef     UINT16      COUNTING;
#define     first       1
#define     second      0x0002
#define     third       3
#define     fourth      0x0004
```

 Copyright © TCG 2006-2020

4.3 Data Type Aliases (typedefs)

When a group of named items is assigned a type, it is placed in a table that has a title starting with "Definition of Types." In this specification, defined types have names that use all upper-case characters.

The table in Example 1 shows how typedefs would be defined in this specification and Example 2 shows the C-compatible code that might be produced from that table by an automated process.

EXAMPLE 1

Table xx — Definition of Types for Some Purpose

Type	Name	Description
unsigned short	UINT16	
UINT16	SOME_TYPE	
unsigned long	UINT32	
UINT32	LAST_TYPE	

EXAMPLE 2

```
/* C language equivalent of the typedefs from the table above */
typedef unsigned short    UINT16;
typedef UINT16            SOME_TYPE;
typedef unsigned long     UINT32;
typedef UINT32            LAST_TYPE;
```

4.4 Enumerations

A table that defines an enumerated data type will start with the word "Definition" and end with "Values."

A value in parenthesis will denote the intrinsic data size of the value and may have the values "INT8", "UINT8", "INT16", "UINT16", "INT32", and "UINT32." If this value is not present, "UINT16" is assumed.

Most C compilers set the type of an enumerated value to be an integer on the machine – often 16 bits – but this is not always consistent. To ensure interoperability, the enumeration values may not exceed 32,384.

The table in Example 1 shows how an enumeration would be defined in this specification. Example 2 shows the C code that might be produced from that table by an automated process.

EXAMPLE 1

Table xx — Definition of (UINT16) CARD_SUIT Values

Suit Names	Value	Description
CLUBS	0x0000	
DIAMONDS	0x000D	
HEARTS	0x001A	
SPADES	0x0027	

EXAMPLE 2

```
/* C language equivalent of the structure defined in the table above */
typedef enum {
    CLUBS       =   0x0000,
    DIAMONDS    =   0x000D,
    HEARTS      =   0x001A,
    SPADES      =   0x0027
} CARD_SUIT;
```

 Copyright © TCG 2006-2020

4.5 Interface Type

An interface type is used for an enumeration that is checked by the unmarshaling code. This type is defined for purposes of automatic generation of the code that will validate the type. The title will start with the keyword “Definition” and end with the keyword “Type.” A value in parenthesis indicates the base type of the interface. The table may contain an entry that is prefixed with the “#” character to indicate the response code if the validation code determines that the input parameter is the wrong type.

EXAMPLE 1

Table xx — Definition of (CARD_SUIT) RED_SUIT Type

Values	Comments
HEARTS	
DIAMONDS	
#TPM_RC_SUIT	response code returned when the unmarshaling of this type fails NOTE TPM_RC_SUIT is an example and no such response code is actually defined in this specification.

EXAMPLE 2

```
/* Validation code that might be automatically generated from table above */
if((*target != HEARTS) && (*target != DIAMONDS))
    return TPM_RC_SUIT;
```

In some cases, the allowed values are numeric values with no associated mnemonic. In such a case, the list of numeric values may be given a name. Then, when used in an interface definition, the name would have a "$" prefix to indicate that a named list of values should be substituted.

To illustrate, assume that the implementation only supports two sizes (1024 and 2048 bits) for keys associated with some algorithm (MY algorithm).

EXAMPLE 3

Table xx — Defines for MY Algorithm Constants

Name	Value	Comments
MY_KEY_SIZES_BITS	{1024, 2048}	braces because this is a list value

 Copyright © TCG 2006-2020

Then, whenever an input value would need to be a valid MY key size for the implementation, the value $MY_KEY_SIZES_BITS could be used. Given the definition for MY_KEY_SIZES_BITS in example 3 above, the tables in example 4 and 5 below, are equivalent.

EXAMPLE 4

Table xx — Definition of (UINT16) MY_KEY_BITS Type

Parameter	Description
{1024, 2048}	the number of bits in the supported key

EXAMPLE 5

Table xx — Definition of (UINT16) MY_KEY_BITS Type

Parameter	Description
$MY_KEY_SIZES_BITS	the number of bits in the supported key

4.6 Arrays

Arrays are denoted by a value in square brackets ("[ ]") following a parameter name. The value in the brackets may be either an integer value such as "[20]" or the name of a component of the same structure that contains the array.

The table in Example 1 shows how a structure containing fixed and variable-length arrays would be defined in this specification. Example 2 shows the C code that might be produced from that table by an automated process.

EXAMPLE 1

Table xx — Definition of A_STRUCT Structure

Parameter	Type	Description
array1[20]	UINT16	an array of 20 UINT16s
a_size	UINT16	
array2[a_size]	UINT32	an array of UINT32 values that has a number of elements determined by a_size above

EXAMPLE 2

```
/* C language equivalent of the typedefs from the table above */
typedef struct {
    UINT16      array1[20];
    UINT16      a_size;
    UINT32      array2[];
} A_STRUCT;
```

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

4.7 Structure Definitions

The tables used to define structures have a title that starts with the word "Definition" and ends with "Structure." The first column of the table will denote the reference names for the structure members; the second column the data type of the member; and the third column a synopsis of the use of the element.

The table in Example 1 shows an example of how a structure would be defined in this specification and Example 2 shows the C code that might be produced from the table by an automated process. Example 3 illustrates the type of unmarshaling code that could be generated using the information available in the table.

EXAMPLE 1

Table xx — Definition of SIMPLE_STRUCTURE Structure

Parameter	Type	Description
tag	TPM_ST	
value1	INT32	
value2	INT32	

EXAMPLE 2

```
/* C language equivalent of the structure defined in the table above */
typedef struct {
    TPM_ST      tag;
    INT32       value1
    INT32       value2;
} SIMPLE_STRUCTURE;
```

EXAMPLE 3

```
TPM_RC SIMPLE_STRUCTURE_Unmarshal(SIMPLE_STRUCTURE *target, BYTE **buffer, INT32 *size)
{
    TPM_RC      rc;
    // If unmarshal of tag succeeds
    rc = TPM_ST_Unmarshal((TPM_ST *)&(target->tag), buffer, size
    If(rc  == TPM_RC_SUCCESS)
    {
         // then unmarshal value1,
        rc = INT32_Unmarshal((INT32 *)&(target->value1, buffer, size);
        // and if that succeeds...
        if(rc  == TPM_RC_SUCCESS)
        {
            // then unmarshal the value 2
            rc = INT32_Unmarshal((INT32 *)&(target->value2, buffer, size);
        }
    }
    return rc;
}
```

 Copyright © TCG 2006-2020

A table may have a term in {}. This indicates that the table is conditionally compiled. It is commonly used when a table's inclusion is based on the implementation of a cryptographic algorithm. See, for example, Table 172 — Definition of (TPM_ALG_ID) {RSA} TPMI_ALG_RSA_DECRYPT Type, which is dependent on the RSA algorithm.

4.8 Conditional Types

An interface type may have a conditional value. This value is indicated by a “+” prepended to the name of the value. When this type is referenced in a structure, a “+” appended to the reference indicates that the instance allows the conditional value to be returned. If the reference does not has an appended “+”, then the conditional type is not allowed.

EXAMPLE 1 Table 65 defining TPMI_ALG_HASH indicates that TPM_ALG_NULL is a conditional type. TPMI_ALG_HASH is a member of the TPMS_SCHEME_XOR structure and that reference is TPMI_ALG_HASH+, indicating that TPM_ALG_NULL is an allowed value for hashAlg. TPMI_ALG_HASH is also referenced in TPMS_PCR_SELECTION. In that structure the TPMI_ALG_HASH does not have an appended “+”, so TPM_ALG_NULL would not be an allowed value for hash.

NOTE In many cases, the input values are algorithm IDs. When two collections of algorithm IDs differ only because one collection allows TPM_ALG_NULL and the other does not, it is preferred that there not be two completely different enumerations because this leads to many casts. To avoid this, the “+” can be added to a TPM_ALG_NULL value in the table defining the type. When the use of that type allows TPM_ALG_NULL to be in the set, the use would append a “+” to the instance.

When a type with a conditional value is referenced within a structure or union and the type reference has a “+” prepended to the type, it allows the references to that structure to treat it as if it had a conditional type. That means that a reference to that structure may have a “+” appended to the type. When the “+” is present in the structure/union reference, then the conditional value of the conditional type within the structure/union is allowed.

EXAMPLE 2 Table 141 — Definition of TPMT_SYM_DEF_OBJECT Structure defines the TPMT_SYM_DEF_OBJECT. The algorithm element of that structure is a TPMI_ALG_SYM_OBJECT with a “+” prepended. This means that when a TPMT_SYM_DEF_OBJECT is referenced, the reference may have an appended “+” as it does in the definition of the symmetric parameter of TPMS_ASYM_PARMS. The “+” in TPMA_ASYM_PARMS means that the algorithm parameter in the TPMT_SYM_DEF_OBJECT may have the conditional value (TPM_ALG_NULL).

EXAMPLE 3

Table xx — Definition of (CARD_SUIT) TPMI_CARD_SUIT Type

Values	Comments
SPADES	
HEARTS	
DIAMONDS	
CLUBS	
+JOKER	an optional value that may be allowed
#TPM_RC_SUIT	response code returned when the input value is not one of the values above

4.9 Unions

4.9.1 Introduction

A union allows a structure to contain a variety of structures or types. The union has members, only one of which is present at a time. Three different tables are required to fully characterize a union so that it may be communicated on the TPM interface and used by the TPM:

- union definition;
- union instance; and
- union selector definition.

4.9.2 Union Definition

The table in Example 1 illustrates a union definition. The title of a union definition table starts with "Definition" and ends with "Union." The "Parameter" column of a union definition lists the different names that are used when referring to a specific type. The "Type" column identifies the data type of the member. The "Selector" column identifies the value that is used by the marshaling and unmarshaling code to determine which case of the union is present.

If a parameter is the keyword "null" or the type is empty, then this denotes a selector with no contents. The table in Example 1 illustrates a union in which a conditional null selector is allowed to indicate an empty union member.

Example 2 shows how the table would be converted into C-compatible code.

The expectation is that the unmarshaling code for the union will validate that the selector for the union is one of values in the selector list.

EXAMPLE 1

Table xx — Definition of NUMBER_UNION Union

Parameter	Type	Selector	Description
a_byte	BYTE	BYTE_SELECT	
an_int	int	INT_SELECT	
a_float	float	FLOAT_SELECT	
+null		NULL_SELECT	the empty branch

EXAMPLE 2

```
// C-compatible version of the union defined in the table above
typedef union {
    BYTE            a_byte;
    int             an_int;
    float           a_float;
} NUMBER_UNION;
```

 Copyright © TCG 2006-2020

EXAMPLE 3

```
// Possible auto-generated code to unmarshal a union in Example 2 based on the
// input value of selector
TPM_RC NUMBER_UNION_Unmarshal(NUMBER_UNION *target, BYTE **buffer,
                              INT32 *size, UINT32 selector)
{
    switch (selector) {
    case BYTE_SELECT:
        return BYTE_Unmarshal((BYTE *)&(target->a_byte), buffer, size);
    case INT_SELECT:
        return INT_Unmarshal((int *)&(target->an_int), buffer, size);
    case FLOAT_SELECT:
        return FLOAT_Unmarshal((float *)&(target->a_float), buffer, size);
    case NULL_SELECT:
        return TPM_RC_SUCCESS;
}
```

A table may have a type with no selector. This is used when the first part of the structure for all union members is identical. This type is a programming convenience, allowing code to reference the common members without requiring a case statement to determine the specific structure. In object oriented programming terms, this type is a superclass and the types with selectors are subclasses. Since there is no selector, this union member cannot be marshaled or unmarshaled.

EXAMPLE 4 Table 188 has an 'any' parameter with no selector. Any of the other union members may be cast to TPMS_SCHEME_HASH, since all begin with TPMI_ALG_HASH.

4.9.3 Union Instance

When a union is used in a structure that is sent on the interface, the structure will minimally contain a selector and a union. The selector value indicates which of the possible union members is present so that the unmarshaling code can unmarshal the correct type. The selector may be any of the parameters that occur in the structure before the union instance. To denote the structure parameter that is used as the selector, its name is in brackets ("[ ]") placed before the parameter name associated with the union.

The table in Example 1 shows the definition of a structure that contains a union and a selector. Example 2 shows how the table would be converted into C-compatible code and Example 3 shows how the unmarshaling code would handle the selector.

EXAMPLE 1

Table xx — Definition of STRUCTURE_WITH_UNION Structure

Parameter	Type	Description
select	NUMBER_SELECT	a value indicating the type in *number*
[select] number	NUMBER_UNION	a union as shown in 4.9.2

EXAMPLE 2

```
// C-compatible version of the union structure in the table above
typedef struct {
    NUMBER_SELECT   select;
    NUMBER_UNION    number;
} STRUCT_WITH_UNION;
```

 Copyright © TCG 2006-2020

EXAMPLE 3

```
// Possible unmarshaling code for the structure above
TPM_RC STRUCT_WITH_UNION_Unmarshal(STRUCT_WITH_UNION *target, BYTE **buffer, INT32 *size)
{
    TPM_RC          rc;
    // Unmarshal the selector value
    rc = NUMBER_SELECT_Unmarshal((NUMBER_SELECT *)&target->select, buffer, size)
    if(rc != TPM_RC_SUCCESS)
        return rc;
    // Use the unmarshaled selector value to indicate to the union unmarshal
    // function which unmarshaling branch to follow.
    return(NUMBER_UNION_Unmarshal((NUMBER_UNION *)&(target->number),
                                  buffer, size, (UINT32)target->select);
}
```

4.9.4 Union Selector Definition

The selector definition limits the values that are used in unmarshaling a union. Two different selector sets applied to the same union define different types.

For the union in 4.9.2, a selector definition should be limited to no more than four values, one for each of the union members. The selector definition could have fewer than four values.

In Example 1, the table defines a value for each of the union members.

EXAMPLE 1

Table xx — Definition of (INT8) NUMBER_SELECT Values <IN>

Name	Value	Comments
BYTE_SELECT	3	
INT_SELECT	2	
FLOAT_SELECT	1	
NULL_SELECT	0	

The unmarshaling code would limit the input values to the defined values. When the NUMBER_SELECT is used in the union instance of 4.9.3, any of the allowed union members of NUMBER_UNION could be present.

A different selection could be used to limit the values in a specific instance. To get the different selection, a new structure is defined with a different selector. The table in example 2 illustrates a way to subset the union. The base type of the selection is NUMBER_SELECT so a NUMBER_SELECT will be unmarshaled before the checks are made to see if the value is in the correct range for JUST_INTEGERS types. If the base type had been UINT8, then no checking would occur prior to checking that the value is in the allowed list. In this particular case, the effect is the same in either case since the only values that will be accepted by the unmarshaling code for JUST_INTEGER are BYTE_SELECT and INT_SELECT.

EXAMPLE 2

Table xx — Definition of (NUMBER_SELECT) AN_INTEGER Type <IN>

Values	Comments
{BYTE_SELECT, INT_SELECT}	list of allowed values

NOTE Since NULL_SELECT is not in the list of values accepted as a JUST_INTEGER, the "+" modifier will have no effect if used for a JUST_INTEGERS type shown in Example 3.

 Copyright © TCG 2006-2020

The selector in Example 2 can then be used in a subset union as shown in Example 3.

EXAMPLE 3

Table xx — Definition of JUST_INTEGERS Structure

Parameter	Type	Description
select	AN_INTEGER	a value indicating the type in *number*
[select] number	NUMBER_UNION	a union as shown in 4.9.2

4.10 Bit Field Definitions

A table that defines a structure containing bit fields has a title that starts with “Definition” and ends with “Bits.” A type identifier in parentheses in the title indicates the size of the datum that contains the bit fields.

When the bit fields do not occupy consecutive locations, a spacer field is defined with a name of “Reserved.” Bits in these spaces are reserved and shall be zero.

The table in Example 1 shows how a structure containing bit fields would be defined in this specification. Example 2 shows the C code that might be produced from that table by an automated process.

When a field has more than one bit, the range is indicated by a pair of numbers separated by a colon (“:”). The numbers will be in high:low order.

EXAMPLE1

Table xx — Definition of (UINT32) SOME_ATTRIBUTE Bits

Bit	Name	Action
0	zeroth_bit	**SET (1)**: what to do if bit is 1 **CLEAR (0):** what to do if bit is 0
1	first_bit	**SET (1)**: what to do if bit is 1 **CLEAR (0):** what to do if bit is 0
6:2	Reserved	A placeholder that spans 5 bits
7	third_bit	**SET (1)**: what to do if bit is 1 **CLEAR (0):** what to do if bit is 0
31:8	Reserved	Placeholder to fill 32 bits

EXAMPLE 2

```
/* C language equivalent of the attributes structure defined in the table above */
typedef struct {
    int zeroth_bit : 1;
    int first_bit  : 1;
    int Reserved3  : 5;
    int third_bit  : 1;
    int Reserved7  : 24;
} SOME_ATTRIBUTE;
```

NOTE The packing of bit fields into an integer is compiler and tool chain dependent. This C language equivalent is valid for a compiler that packs bit fields from the least significant bit to the most significant bit. It is likely to be correct for a little endian processor and likely to be incorrect for a big endian processor.

 Copyright © TCG 2006-2020

4.11 Parameter Limits

A parameter used in a structure may be given a set of values that can be checked by the unmarshaling code. The allowed values for a parameter may be included in the definition of the parameter by appending the values and delimiting them with braces ("{ }"). The values are comma-separated expressions. A range of numbers may be indicated by separating two expressions with a colon (":"). The first number is an expression that represents the minimum allowed value and the second number indicates the maximum. If the minimum or maximum value expression is omitted, then the range is open-ended.

Lower limits expressed using braces apply only to inputs to the TPM. The lower limit for a value returned by the TPM is determined by input parameters and the TPM implementation. Upper limits expressed using braces apply to both inputs to and outputs from the TPM.

NOTE In many cases, the upper limits are dependent on the TPM implementation. The values for these limits can be determined by accessing the TPM's capabilities.

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

The maximum size of an array may be indicated by putting a "{}" delimited expression following the square brackets ("[ ]") that indicate that the value is an array.

EXAMPLE

Table xx — Definition of B_STRUCT Structure

Parameter	Type	Description
value1 {20:25}	UINT16	a parameter that must have a value between 20 and 25, inclusive
value2 {20}	UINT16	a parameter that must have a value of 20
value3 {:25}	INT16	a parameter that may be no larger than 25 Since the parameter is signed, the minimum value is the largest negative integer that may be expressed in 16 bits.
value4 {20:}		a parameter that must be at least 20
value5 {1,2,3,5}	UINT16	a parameter that may only have one of the four listed values
value6 {1, 2, 10:(10+10)}	UINT32	a parameter that may have a value of 1, 2, or be between 10 and 20
array1[value1]	BYTE	Because the index refers to *value1*, which is a value limited to be between 20 and 25 inclusive, array1 is an array that may have between 20 and 25 octets. This is not the preferred way to indicate the upper limit for an array as it does not indicate the upper bound of the size. NOTE This is a limitation of the current parser. A different parser could associate the range of value1 with this value and compute the maximum size of the array.
array2[value4]{:25}	BYTE	an array that may have between 20 and 25 octets This arrangement is used to allow the automatic code generation to allocate 25 octets to store the largest array2 that can be unmarshaled. The code generation can determine from this expression that *value4* shall have a value of 25 or less. From the definition of *value4* above, it can determine that *value4* must have a value of at least 20.

4.12 Algorithm Macros

4.12.1 Introduction

This specification is intended to be algorithm agile in two different ways. In the first, agility is provided by allowing different subsets of the algorithms listed in the TCG registry. In the second, agility is provided by allowing the list of algorithms in the TCG registry to change without requiring changes to this specification.

This second form of algorithm agility is accomplished by using placeholder tokens that represent all of the algorithms of a particular type. The type of the algorithm is indicated by the letters in the Type column of the TPM_ALG_ID table in the TCG registry.

 Copyright © TCG 2006-2020

The use of these tokens is described in the remainder of this clause 4.12.

4.12.2 Algorithm Token Semantics

The string “!ALG” or “!alg” indicates the algorithm token. This token may be followed by an algorithm type selection. The presence of the type selection is indicated by a period (“.”) following the token. The selection is all alphanumeric characters following the period.

NOTE In this selection context, the underscore character (“_”) is not considered an alphanumeric character.

The selection is either an exclusive selection or an inclusive selection. An exclusive selection is one for which the Type entry for the algorithm is required to exactly match the type selection of the token. An inclusive selection is one where the Type entry for the algorithm is required to contain all of the characters of the selection but may contain additional attributes.

EXAMPLE 1 The “!ALG.AX” token would select those algorithms that only have the ‘A’ and ‘X’ types (that is, an asymmetric signing algorithm). The “!ALG.ax” token would select those algorithms that at least have ‘A’ and ‘X’ types but would include algorithms with other types such as ‘ANX’ (asymmetric signing and anonymous asymmetric signing).

When a replacement is made, the token will be replaced by an algorithm root identifier using either upper or lower case. If the algorithm token is part of another word, then the replacement uses upper case characters, otherwise, lower case is used.

NOTE The root identifier of an algorithm is the name in the TPM_ALG_ID table with “TPM_ALG_” removed. For example TPM_ALG_SHA1 has “SHA1” as its root.

The typical use of these tokens follows.

4.12.3 Algorithm Tokens in Unions

A common place for algorithm tokens is in a union of values that are dependent on the type of the algorithm

EXAMPLE 1 An algorithm token indicating all hashes would be “!ALG.H” and could be used in a table to indicate that a union contains all defined hashes.

Table A — Definition of TPMU_HA Union

Parameter	Type	Selector	Description
!ALG.H [!ALG_DIGEST_SIZE]	BYTE	TPM_ALG_!ALG	all hashes
null		TPM_ALG_NULL	

If the TCG registry only contained SHA1, SHA256, and the SM3_256 hash algorithm identifiers, then the table above would be semantically equivalent to:

 Copyright © TCG 2006-2020

Table xx — Definition of TPMU_HA Union

Parameter	Type	Selector	Description
sha1 [SHA1_DIGEST_SIZE]	BYTE	TPM_ALG_SHA1	
sha256 [SHA256_DIGEST_SIZE]	BYTE	TPM_ALG_SHA256	
sm3_256 [SM3_256_DIGEST_SIZE]	BYTE	TPM_ALG_SM3_256	
null		TPM_ALG_NULL	

As shown in table A, the case of the replacement is determined by context. When !ALG is not an element of a longer name, then lower case characters are used. When !ALG is part of a longer name (indicated by leading or trailing underscore ("_"), then upper case is used for the replacement.

Only one occurrence of the algorithm type (such as !ALG.H) is required for a line. If a line contains multiple list selections they are required to be identical.

If a table contains multiple lines with algorithm tokens, then each line is expanded separately.

4.12.4 Algorithm Tokens in Interface Types

An interface type is often used with a union to create a tagged structure – the structure contains a union and a tag to indicate which of the union elements is actually present. The interface type for a tagged structure will usually contain the same elements as the union.

EXAMPLE If SHA1, SHA256, and SM3_256 are the only defined hash algorithms, then an interface type to select a hash would be:

Table xx — Definition of (TPM_ALG_ID) TPMI_ALG_HASH Type

Values	Comments
TPM_ALG_SHA1	example
TPM_ALG_SHA256	example
TPM_ALG_SM3_256	example
+TPM_ALG_NULL	
#TPM_RC_HASH	

An equivalent table may be represented using an algorithm macro.

Table xx — Definition of (TPM_ALG_ID) TPMI_ALG_HASH Type

Values	Comments
TPM_ALG_!ALG.H	all hash algorithms defined by the TCG
+TPM_ALG_NULL	
#TPM_RC_HASH	

4.12.5 Algorithm Tokens for Table Replication

When a table is used to define an algorithm-specific value, that table may be replicated using the algorithm replacement token to create a table with values specific to the algorithm type. This type of replication is indicated by using an algorithm token in the name of the table.

EXAMPLE If AES and SM4 are the only defined symmetric block ciphers, then:

 Copyright © TCG 2006-2020

Table xx — Definition of {!ALG.S} (TPM_KEY_BITS) TPMI_!ALG_KEY_BITS Type

Parameter	Description
$!ALG_KEY_SIZES_BITS	number of bits in the key
#TPM_RC_VALUE	error when key size is not supported

has the same meaning as:

Table xx — Definition of {AES} (TPM_KEY_BITS) TPMI_AES_KEY_BITS Type

Parameter	Description
$AES_KEY_SIZES_BITS	number of bits in the key
#TPM_RC_VALUE	error when key size is not supported

Table xx — Definition of {SM4} (TPM_KEY_BITS) TPMI_SM4_KEY_BITS Type

Parameter	Description
$SM4_KEY_SIZES_BITS	number of bits in the key
#TPM_RC_VALUE	error when key size is not supported

 Copyright © TCG 2006-2020

4.13 Size Checking

In some structures, a size field is present to indicate the number of octets in some subsequent part of the structure. In the B_STRUCT table in 4.11, *value4* indicates how many octets to unmarshal for *array2*. This semantic applies when the size field determines the number of octets to unmarshal. However, in some cases, the subsequent structure is self-defining. If the size precedes a parameter that is not an octet array, then the unmarshaled size of that parameter is determined by its data type. The table in Example 1 shows a structure where the size parameter would nominally indicate the number of octets in the remainder of the structure.

EXAMPLE 1

Table xx — Definition of C_STRUCT Structure

Parameter	Type	Comments
size	UINT16	the expected size of the remainder of the structure
anInteger	UINT32	a 4-octet value

In this particular case, the value of size would be incorrect if it had any value other than 4. So that the table parser is able to know that the purpose of the size parameter is to define the number of octets expected in the remainder of the structure, an equal sign (“=”) is appended to the parameter name.

In the example below, the *size*= causes the parser to generate validation code that will check that the unmarshaled size of *someStructure* and *someData* adds to the value unmarshaled for *size*. When the “=” decoration is present, a value of zero is not allowed for the size.

EXAMPLE 2

Table xx — Definition of D_STRUCT Structure

Parameter	Type	Comments
size=	UINT16	the size of a structure The “=” indicates that the TPM is required to validate that the remainder of the D_STRUCT structure is exactly the value in *size*. That is, the number of bytes in the input buffer used to successfully unmarshal *someStructure* must be the same as *size*.
someStructure	A_STRUCT	a structure to be unmarshaled The size of the structure is computed when it is unmarshaled. Because an “=” is present on the definition of *size,* the TPM is required to validate that the unmarshaled size exactly matches *size*.
someData	UINT32	a value

4.14 Data Direction

A structure or union may be input (IN), output (OUT), or internal. An input structure is sent to the TPM and is unmarshaled by the TPM. An output structure is sent from the TPM and is marshaled by the TPM. An internal structure is not used outside of the TPM except that it may be included in a saved context.

By default, structures are assumed to be both IN and OUT and the code generation tool will generate both marshaling and unmarshaling code for the structure. This default may be changed by using values enclosed in angle brackets (“<>”) as part of the table title. If the angle brackets are empty, then the

 Copyright © TCG 2006-2020

structure is internal and neither marshaling nor unmarshaling code is generated. If the angle brackets contain the letter "I" (such as in "IN" or "in" or "i"), then the structure is input and unmarshaling code will be generated. If the angle brackets contain the letter "O" (such as in "OUT" or "out" or "o"), then the structure is output and marshaling code will be generated.

EXAMPLE 1 Both of the following table titles would indicate a structure that is used in both input and output

Table xx — Definition of TPMS_A Structure

Table xx — Definition of TPMS_A Structure <IN/OUT>

EXAMPLE 2 The following table title would indicate a structure that is used only for input

Table xx — Definition of TPMS_A Structure <IN>

EXAMPLE 3 The following table title would indicate a structure that is used only for output

Table xx — Definition of TPMS_A Structure <OUT>

 Copyright © TCG 2006-2020

4.15 Structure Validations

By default, when a structure is used for input to the TPM, the code generation tool will generate the unmarshaling code for that structure. Auto-generation may be suppressed by adding an "S" within the angle brackets.

EXAMPLE The following table titles indicate a structure for which the auto-generation of the validation code is to be suppressed.

Table xx — Definition of TPMT_A Structure <S>

Table xx — Definition of TPMT_A Structure <IN, S>

Table xx — Definition of TPMT_A Structure <IN/OUT, S>

4.16 Name Prefix Convention

Parameters are constants, variables, structures, unions, and structure members. Structure members are given a name that is indicative of its use, with no special prefix. The other parameter types are named according to their type with their name starting with "TPMx_", where "x" is an optional character to indicate the data type.

In some cases, additional qualifying characters will follow the underscore. These are generally used when dealing with an enumerated data type.

Table 1 — Name Prefix Convention

Prefix	Description
TPM	an indication/signal from the TPM's system interface
TPM_	a constant or an enumerated type
TPM2_	a command defined by this specification
TPM2B_	a structure that is a sized buffer where the size of the buffer is contained in a 16-bit, unsigned value The first parameter is the size in octets of the second parameter. The second parameter may be any type.
TPMA_	a structure where each of the fields defines an attribute and each field is usually a single bit All the attributes in an attribute structure are packed with the overall size of the structure indicated in the heading of the attribute description (UINT8, UINT16, or UINT32).
TPM_ALG_	an enumerated type that indicates an algorithm A TPM_ALG_ is often used as a selector for a union.
TPMI_	an interface type The value is specified for purposes of dynamic type checking when unmarshaled.
TPML_	a list length followed by the indicated number of entries of the indicated type This is an array with a length field.
TPMS_	a structure that is not a size buffer or a tagged buffer or a list
TPMT_	a structure with the first parameter being a structure tag, indicating the type of the structure that follows A structure tag may be either a TPM_ST_ or TPM_ALG_ depending on context.
TPMU_	a union of structures, lists, or unions If a union exists, there will normally be a companion TPMT_ that is the expression of the union in a tagged structure, where the tag is the selector indicating which member of the union is present.

 Copyright © TCG 2006-2020

Prefix	Description
TPM_xx_	an enumeration value of a particular type The value of “xx” will be indicative of the use of the enumerated type. A table of “TPM_xx” constant definitions will exist to define each of the TPM_xx_ values. EXAMPLE 1 TPM_CC_ indicates that the type is used for a *commandCode.* The allowed enumeration values will be found in the table defining the TPM_CC constants (Table 12) EXAMPLE 2 TPM_RC_ indicates that the type is used for a *responseCode*. The allowed enumeration values are in Table 16.

4.17 Data Alignment

The data structures in this TPM 2.0 Part 2 use octet alignment for all structures. When used in a table to indicate a maximum size, the `sizeof()` function returns the octet-aligned size of the structure, with no padding.

4.18 Parameter Unmarshaling Errors

The TPM commands are defined in TPM 2.0 Part 3. The command definition includes C code that details the actions performed by that command. The code is written assuming that the parameters of the command have been unmarshaled.

NOTE 1 An implementation is not required to process parameters in this manner or to separate the parameter parsing from the command actions. This method was chosen for the specification so that the normative behavior described by the detailed actions would be clear and unencumbered.

Unmarshaling is the process of processing the parameters in the input buffer and preparing the parameters for use by the command-specific action code. No data movement need take place but it is required that the TPM validate that the parameters meet the requirements of the expected data type as defined in this TPM 2.0 Part 2.

When an error is encountered while unmarshaling a command parameter, an error response code is returned and no command processing occurs. A table defining a data type may have response codes embedded in the table to indicate the error returned when the input value does not match the parameters of the table.

EXAMPLE 1

Table 12 has a listing of TPM command code values. The last row in the table contains "#TPM_RC_COMMAND_CODE" indicating the response code that is returned if the TPM is unmarshaling a value that it expects to be a TPM_CC and the input value is not in the table.

NOTE 2 In the reference implementation, a parameter number is added to the response code so that the offending parameter can be isolated.

 Copyright © TCG 2006-2020

In many cases, the table contains no specific response code value and the return code will be determined as defined in Table 2.

Table 2 — Unmarshaling Errors

Response code	Usage
TPM_RC_INSUFFICIENT	the input buffer did not contain enough octets to allow unmarshaling of the expected data type;
TPM_RC_RESERVED_BITS	a non-zero value was found in a reserved field of an attribute structure (TPMA_)
TPM_RC_SIZE	the value of a size parameter is larger or smaller than allowed
TPM_RC_VALUE	A parameter does not have one of its allowed values
TPM_RC_TAG	A parameter that should be a structure tag has a value that is not supported by the TPM

In some commands, a parameter may not be used because of various options of that command. However, the unmarshaling code is required to validate that all parameters have values that are allowed by the TPM 2.0 Part 2 definition of the parameter type even if that parameter is not used in the command actions.

 Copyright © TCG 2006-2020

5 Base Types

5.1 Primitive Types

The types listed in Table 3 are the primitive types on which all of the other types and structures are based. The values in the "Type" column should be edited for the compiler and computer on which the TPM is implemented. The values in the "Name" column should remain the same because these values are used in the remainder of the specification.

NOTE The types are compatible with the C99 standard and should be defined in stdint.h that is provided with a C99-compliant compiler;

The parameters in the Name column should remain in the order shown.

Table 3 — Definition of Base Types

Type	Name	Description
uint8_t	UINT8	unsigned, 8-bit integer
uint8_t	BYTE	unsigned 8-bit integer
int8_t	INT8	signed, 8-bit integer
int	BOOL	a bit in an `int` This is not used across the interface but is used in many places in the code. If the type were sent on the interface, it would have to have a type with a specific number of bytes.
uint16_t	UINT16	unsigned, 16-bit integer
int16_t	INT16	signed, 16-bit integer
uint32_t	UINT32	unsigned, 32-bit integer
int32_t	INT32	signed, 32-bit integer
uint64_t	UINT64	unsigned, 64-bit integer
int64_t	INT64	signed, 64-bit integer

5.2 Specification Logic Value Constants

Table 4 — Defines for Logic Values

Name	Value	Description
TRUE	1	
FALSE	0	
YES	1	
NO	0	
SET	1	
CLEAR	0	

 Copyright © TCG 2006-2020

5.3 Miscellaneous Types

These types are defined either for compatibility with previous versions of this specification or for clarity of this specification.

Table 5 — Definition of Types for Documentation Clarity

Type	Name	Description
UINT32	TPM_ALGORITHM_ID	this is the 1.2 compatible form of the TPM_ALG_ID
UINT32	TPM_MODIFIER_INDICATOR	
UINT32	TPM_AUTHORIZATION_SIZE	the *authorizationSize* parameter in a command
UINT32	TPM_PARAMETER_SIZE	the *parameterSize* parameter in a command
UINT16	TPM_KEY_SIZE	a key size in octets
UINT16	TPM_KEY_BITS	a key size in bits

 Copyright © TCG 2006-2020

6 Constants

6.1 TPM_SPEC (Specification Version Values)

These values are readable with TPM2_GetCapability() (see 6.13 for the format).

NOTE 1 This table will require editing when the specification is updated.

NOTE 2 The year and day of year are those of this specification if the TPM does not implement errata. If the TPM implements errata, the values indicate the release date of the errata document. There is no provision for indicating that not all errata are implemented.

Table 6 — Definition of (UINT32) TPM_SPEC Constants <>

Name	Value	Comments
TPM_SPEC_FAMILY	0x322E3000	ASCII “2.0” with null terminator
TPM_SPEC_LEVEL	00	the level number for the specification
TPM_SPEC_VERSION	159	the version number of the spec (001.59 * 100)
TPM_SPEC_YEAR	2019	the year of the version
TPM_SPEC_DAY_OF_YEAR	312	the day of the year (November 8)

6.2 TPM_GENERATED

This constant value differentiates TPM-generated structures from non-TPM structures.

Table 7 — Definition of (UINT32) TPM_GENERATED Constants <O>

Name	Value	Comments
TPM_GENERATED_VALUE	0xff544347	0xFF ‘TCG’ (FF 54 43 47_{16})

 Copyright © TCG 2006-2020

6.3 TPM_ALG_ID

The TCG maintains a registry of all algorithms that have an assigned algorithm ID. That registry is the definitive list of algorithms that may be supported by a TPM.

NOTE Inclusion of an algorithm does NOT indicate that the necessary claims of the algorithm are available under reasonable and non-discriminatory (RAND) terms from a TCG member.

Table 9 is an informative example of a TPM_ALG_ID constants table in the TCG Algorithm registry. Table 9 is provided for illustrative purposes only.

An algorithm ID is often used like a tag to determine the type of a structure in a context-sensitive way. The values for TPM_ALG_ID shall be in the range of 00 00_{16} – 7F FF_{16}. Other structure tags will be in the range 80 00_{16} – FF FF_{16}.

NOTE In TPM 1.2, these were defined as 32-bit constants. This specification limits the future size of the algorithm ID to 16 bits. The TPM_ALGORITHM_ID data type will continue to be a 32-bit number.

An algorithm shall not be assigned a value in the range 00 $C1_{16}$ – 00 $C6_{16}$ in order to prevent any overlap with the command structure tags used in TPM 1.2.

The implementation of some algorithms is dependent on the presence of other algorithms. When there is a dependency, the algorithm that is required is listed in column labeled "D" (dependent) in Table 9.

EXAMPLE Implementation of TPM_ALG_RSASSA requires that the RSA algorithm be implemented.

TPM_ALG_KEYEDHASH and TPM_ALG_NULL are required of all TPM implementations.

Table 8 — Legend for TPM_ALG_ID Table

Column Title	Comments
Algorithm Name	the mnemonic name assigned to the algorithm
Value	the numeric value assigned to the algorithm
Type	The allowed values are: **A** – asymmetric algorithm with a public and private key **S** – symmetric algorithm with only a private key **H** – hash algorithm that compresses input data to a digest value or indicates a method that uses a hash **X** – signing algorithm **N** – an anonymous signing algorithm **E** – an encryption algorithm **M** – a method such as a mask generation function **O** – an object type
C	(**C**lassification) The allowed values are: **A** – Assigned **S** – TCG Standard **L** – TCG Legacy
Dep	(**D**ependent) Indicates which other algorithm is required to be implemented if this algorithm is implemented
Reference	the reference document that defines the algorithm
Comments	clarifying information

 Copyright © TCG 2006-2020

6.4 TPM_ECC_CURVE

The TCG maintains a registry of all curves that have an assigned curve identifier. That registry is the definitive list of curves that may be supported by a TPM.

Table 10 is a copy of the TPM_ECC_CURVE constants table in the TCG registry as of the date of publication of this specification. Table 10 is provided for illustrative purposes only.

Table 10 — Definition of (UINT16) {ECC} TPM_ECC_CURVE Constants <IN/OUT>

Name	Value	Comments
+TPM_ECC_NONE	0x0000

6.5 TPM_CC (Command Codes)

6.5.1 Format

A command is a 32-bit structure with fields assigned as shown in Figure 1. If V is SET, the command is vendor specific. If V is CLEAR, the command is not vendor specific.

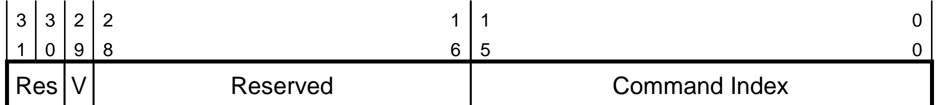

Figure 1 — Command Format

Table 11 — TPM Command Format Fields Description

Bit	Name	Definition
15:0	Command Index	the index of the command
28:16	Reserved	shall be zero
29	V	vendor specific
31:30	Res	shall be zero

#TPM_RC_COMMAND_CODE			

NOTE 1 A TPM may implement either TPM2_HMAC()/TPM2_HMAC_Start() or TPM2_MAC()/TPM2_MAC_Start() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC()/TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC()/TPM2_HMAC_Start(), but a TPM that supports TPM2_HMAC()/TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

6.6 TPM_RC (Response Codes)

6.6.1 Description

Each return from the TPM has a 32-bit response code. The TPM will always set the upper 20 bits (31:12) of the response code to 0 00 00_{16} and the low-order 12 bits (11:00) will contain the response code.

When a command succeeds, the TPM shall return TPM_RC_SUCCESS (0 00_{16}) and will update any authorization-session nonce associated with the command.

When a command fails to complete for any reason, the TPM shall return

- a TPM_ST (UINT16) with a value of TPM_TAG_RSP_COMMAND or TPM_ST_NO_SESSIONS, followed by
- a UINT32 (*responseSize*) with a value of 10, followed by
- a UINT32 containing a response code with a value other than TPM_RC_SUCCESS.

Commands defined in this specification will use a tag of either TPM_ST_NO_SESSIONS or TPM_ST_SESSIONS. Error responses will use a tag value of TPM_ST_NO_SESSIONS and the response code will be as defined in this specification. Commands that use tags defined in the TPM 1.2 specification will use TPM_TAG_RSP_COMMAND in an error and a response code defined in TPM 1.2.

If the tag of the command is not a recognized command tag, the TPM error response will differ depending on TPM 1.2 compatibility. If the TPM supports 1.2 compatibility, the TPM shall return a tag of TPM_TAG_RSP_COMMAND and an appropriate TPM 1.2 response code (TPM_BADTAG = 00 00 00 $1E_{16}$). If the TPM does not have compatibility with TPM 1.2, the TPM shall return TPM_ST_NO_SESSION and a response code of TPM_RC_TAG.

When a command fails, the TPM shall not update the authorization-session nonces associated with the command and will not close the authorization sessions used by the command. Audit digests will not be updated on an error. Unless noted in the command actions, a command that returns an error shall leave the state of the TPM as if the command had not been attempted. The exception to this principle is that a failure due to an authorization failure may update the dictionary-attack protection values.

6.6.2 Response Code Formats

The response codes for this specification are defined such that there is no overlap between the response codes used for this specification and those assigned in previous TPM specifications.

The formats defined in this clause only apply when the tag for the response is TPM_ST_NO_SESSIONS.

The response codes use two different format groups. One group contains the TPM 1.2 compatible response codes and the response codes for this specification that are not related to command parameters. The second group contains the errors that may be associated with a command parameter, handle, or session.

 Copyright © TCG 2006-2020

Figure 2 shows the format for the response codes when bit 7 is zero.

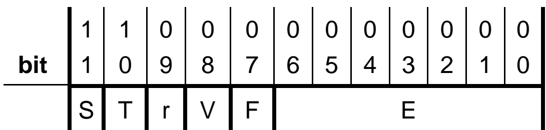

Figure 2 — Format-Zero Response Codes

The field definitions are:

Table 13 — Format-Zero Response Codes

Bit	Name	Definition
06:00	E	the error number The interpretation of this field is dependent on the setting of the F and S fields.
07	F	format selector **CLEAR** when the format is as defined in this Table 13 or when the response code is TPM_RC_BAD_TAG.
08	V	version **SET (1)**: The error number is defined in this specification and is returned when the response tag is TPM_ST_NO_SESSIONS. **CLEAR (0)**: The error number is defined by a previous TPM specification. The error number is returned when the response tag is TPM_TAG_RSP_COMMAND. NOTE In any error number returned by a TPM, the F (bit 7) and V (bit 8) attributes shall be CLEAR when the response tag is TPM_TAG_RSP_COMMAND value used in TPM 1.2.
09	Reserved	shall be zero.
10	T	TCG/Vendor indicator **SET (1):** The response code is defined by the TPM vendor. **CLEAR (0):** The response code is defined by the TCG (a value in this specification). NOTE This attribute does not indicate a vendor-specific code unless the *F* attribute (bit[07]) is CLEAR.
11	S	severity **SET (1)**: The response code is a warning and the command was not necessarily in error. This command indicates that the TPM is busy or that the resources of the TPM have to be adjusted in order to allow the command to execute. **CLEAR (0)**: The response code indicates that the command had an error that would prevent it from running.

When the format bit (bit 7) is SET, then the error occurred during the unmarshaling or validation of an input parameter to the TPM. Figure 3 shows the format for the response codes when bit 7 is one.

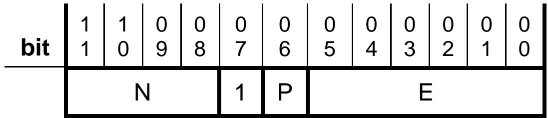

Figure 3 — Format-One Response Codes

There are 64 errors with this format. The errors can be associated with a parameter, handle, or session. The error number for this format is in bits[05:00]. When an error is associated with a parameter, TPM_RC_P (0 40_{16}) is added and N is set to the parameter number.

NOTE 1 In the reference implementation, for a RC_FMT1 response code, a constant of the form RC_Command_parameterName is the one based parameter number (TPM_RC_n) plus TPM_RC_P.

 Copyright © TCG 2006-2020

Example RC_Startup_startupType is the first parameter, TPM_RC_1 (0x100) plus TPM_RC_P (0x40) or 0x140. TPM_RC_VALUE (RC_FMT1 (0x080) + 0x004) + RC_Startup_startupType is thus 0x080 + 0x004 + 0x140 = 0x1c4.

For an error associated with a handle, a parameter number (1 to 7) is added to the N field. For an error associated with a session, a value of 8 plus the session number (1 to 7) is added to the N field. In other words, if P is clear, then a value of 0 to 7 in the N field will indicate a handle error, and a value of 8 – 15 will indicate a session error.

NOTE 2 If an implementation is not able to designate the handle, session, or parameter in error, then P and N will be zero.

The field definitions are:

Table 14 — Format-One Response Codes

Bit	Name	Definition
05:00	E	the error number The error number is independent of the other settings.
06	P	**SET (1):** The error is associated with a parameter. **CLEAR (0):** The error is associated with a handle or a session.
07	F	the response code format selector This field shall be SET for the format in this table.
11:08	N	the number of the handle, session, or parameter in error. The number is one based. See TPM_RC_1 through TPM_RC_F. If P is SET, then this field is the parameter in error. If P is CLEAR, then this field indicates the handle or session in error. Handles use values of N between 0000_2 and 0111_2. Sessions use values between 1000_2 and 1111_2. NOTE Bit 11 distinguishes between handles and sessions. Bits 10:8 000_2 indicate that the number is unspecified.

The groupings of response codes are determined by bits 08, 07, and 06 of the response code as summarized in Table 15.

Table 15 — Response Code Groupings

Bit			
08	07	06	Definition
0	0	x	a response code defined by TPM 1.2 NOTE An “x” in a column indicates that this may be either 0 or 1 and not affect the grouping of the response code.
1	0	x	a response code defined by this specification with no handle, session, or parameter number modifier
x	1	0	a response code defined by this specification with either a handle or session number modifier
x	1	1	a response code defined by this specification with a parameter number modifier

 Copyright © TCG 2006-2020

6.6.3 TPM_RC Values

In general, response codes defined in TPM 2.0 Part 2 will be unmarshaling errors and will have the F (format) bit SET. Codes that are unique to TPM 2.0 Part 3 will have the F bit CLEAR but the V (version) attribute will be SET to indicate that it is a TPM 2.0 response code. See *Response Code Details* in TPM 2.0 Part 1.

NOTE The constant RC_VER1 is used to indicate that the V attribute is SET and the constant RC_FMT1 is used to indicate that the F attribute is SET and that the return code is variable based on handle, session, and parameter modifiers.

Table 16 — Definition of (UINT32) TPM_RC Constants (Actions) <OUT>

Name	Value	Description
TPM_RC_SUCCESS	0x000	
TPM_RC_BAD_TAG	0x01E	defined for compatibility with TPM 1.2
RC_VER1	0x100	set for all format 0 response codes
TPM_RC_INITIALIZE	RC_VER1 + 0x000	TPM not initialized by TPM2_Startup or already initialized
TPM_RC_FAILURE	RC_VER1 + 0x001	commands not being accepted because of a TPM failure NOTE This may be returned by TPM2_GetTestResult() as the *testResult* parameter.
TPM_RC_SEQUENCE	RC_VER1 + 0x003	improper use of a sequence handle
TPM_RC_PRIVATE	RC_VER1 + 0x00B	not currently used
TPM_RC_HMAC	RC_VER1 + 0x019	not currently used
TPM_RC_DISABLED	RC_VER1 + 0x020	the command is disabled
TPM_RC_EXCLUSIVE	RC_VER1 + 0x021	command failed because audit sequence required exclusivity
TPM_RC_AUTH_TYPE	RC_VER1 + 0x024	authorization handle is not correct for command
TPM_RC_AUTH_MISSING	RC_VER1 + 0x025	command requires an authorization session for handle and it is not present.
TPM_RC_POLICY	RC_VER1 + 0x026	policy failure in math operation or an invalid authPolicy value
TPM_RC_PCR	RC_VER1 + 0x027	PCR check fail
TPM_RC_PCR_CHANGED	RC_VER1 + 0x028	PCR have changed since checked.
TPM_RC_UPGRADE	RC_VER1 + 0x02D	for all commands other than TPM2_FieldUpgradeData(), this code indicates that the TPM is in field upgrade mode; for TPM2_FieldUpgradeData(), this code indicates that the TPM is not in field upgrade mode
TPM_RC_TOO_MANY_CONTEXTS	RC_VER1 + 0x02E	context ID counter is at maximum.
TPM_RC_AUTH_UNAVAILABLE	RC_VER1 + 0x02F	authValue or authPolicy is not available for selected entity.
TPM_RC_REBOOT	RC_VER1 + 0x030	a _TPM_Init and Startup(CLEAR) is required before the TPM can resume operation.
TPM_RC_UNBALANCED	RC_VER1 + 0x031	the protection algorithms (hash and symmetric) are not reasonably balanced. The digest size of the hash must be larger than the key size of the symmetric algorithm.

 Copyright © TCG 2006-2020

Name	Value	Description
TPM_RC_COMMAND_SIZE	RC_VER1 + 0x042	command *commandSize* value is inconsistent with contents of the command buffer; either the size is not the same as the octets loaded by the hardware interface layer or the value is not large enough to hold a command header
TPM_RC_COMMAND_CODE	RC_VER1 + 0x043	command code not supported
TPM_RC_AUTHSIZE	RC_VER1 + 0x044	the value of *authorizationSize* is out of range or the number of octets in the Authorization Area is greater than required
TPM_RC_AUTH_CONTEXT	RC_VER1 + 0x045	use of an authorization session with a context command or another command that cannot have an authorization session.
TPM_RC_NV_RANGE	RC_VER1 + 0x046	NV offset+size is out of range.
TPM_RC_NV_SIZE	RC_VER1 + 0x047	Requested allocation size is larger than allowed.
TPM_RC_NV_LOCKED	RC_VER1 + 0x048	NV access locked.
TPM_RC_NV_AUTHORIZATION	RC_VER1 + 0x049	NV access authorization fails in command actions (this failure does not affect lockout.action)
TPM_RC_NV_UNINITIALIZED	RC_VER1 + 0x04A	an NV Index is used before being initialized or the state saved by TPM2_Shutdown(STATE) could not be restored
TPM_RC_NV_SPACE	RC_VER1 + 0x04B	insufficient space for NV allocation
TPM_RC_NV_DEFINED	RC_VER1 + 0x04C	NV Index or persistent object already defined
TPM_RC_BAD_CONTEXT	RC_VER1 + 0x050	context in TPM2_ContextLoad() is not valid
TPM_RC_CPHASH	RC_VER1 + 0x051	cpHash value already set or not correct for use
TPM_RC_PARENT	RC_VER1 + 0x052	handle for parent is not a valid parent
TPM_RC_NEEDS_TEST	RC_VER1 + 0x053	some function needs testing.
TPM_RC_NO_RESULT	RC_VER1 + 0x054	returned when an internal function cannot process a request due to an unspecified problem. This code is usually related to invalid parameters that are not properly filtered by the input unmarshaling code.
TPM_RC_SENSITIVE	RC_VER1 + 0x055	the sensitive area did not unmarshal correctly after decryption – this code is used in lieu of the other unmarshaling errors so that an attacker cannot determine where the unmarshaling error occurred
RC_MAX_FM0	RC_VER1 + 0x07F	largest version 1 code that is not a warning
		New Subsection
RC_FMT1	0x080	This bit is SET in all format 1 response codes The codes in this group may have a value added to them to indicate the handle, session, or parameter to which they apply.
TPM_RC_ASYMMETRIC	RC_FMT1 + 0x001	asymmetric algorithm not supported or not correct
TPM_RC_ATTRIBUTES	RC_FMT1 + 0x002	inconsistent attributes
TPM_RC_HASH	RC_FMT1 + 0x003	hash algorithm not supported or not appropriate
TPM_RC_VALUE	RC_FMT1 + 0x004	value is out of range or is not correct for the context

 Copyright © TCG 2006-2020

Name	Value	Description
TPM_RC_HIERARCHY	RC_FMT1 + 0x005	hierarchy is not enabled or is not correct for the use
TPM_RC_KEY_SIZE	RC_FMT1 + 0x007	key size is not supported
TPM_RC_MGF	RC_FMT1 + 0x008	mask generation function not supported
TPM_RC_MODE	RC_FMT1 + 0x009	mode of operation not supported
TPM_RC_TYPE	RC_FMT1 + 0x00A	the type of the value is not appropriate for the use
TPM_RC_HANDLE	RC_FMT1 + 0x00B	the handle is not correct for the use
TPM_RC_KDF	RC_FMT1 + 0x00C	unsupported key derivation function or function not appropriate for use
TPM_RC_RANGE	RC_FMT1 + 0x00D	value was out of allowed range.
TPM_RC_AUTH_FAIL	RC_FMT1 + 0x00E	the authorization HMAC check failed and DA counter incremented
TPM_RC_NONCE	RC_FMT1 + 0x00F	invalid nonce size or nonce value mismatch
TPM_RC_PP	RC_FMT1 + 0x010	authorization requires assertion of PP
TPM_RC_SCHEME	RC_FMT1 + 0x012	unsupported or incompatible scheme
TPM_RC_SIZE	RC_FMT1 + 0x015	structure is the wrong size
TPM_RC_SYMMETRIC	RC_FMT1 + 0x016	unsupported symmetric algorithm or key size, or not appropriate for instance
TPM_RC_TAG	RC_FMT1 + 0x017	incorrect structure tag
TPM_RC_SELECTOR	RC_FMT1 + 0x018	union selector is incorrect
TPM_RC_INSUFFICIENT	RC_FMT1 + 0x01A	the TPM was unable to unmarshal a value because there were not enough octets in the input buffer
TPM_RC_SIGNATURE	RC_FMT1 + 0x01B	the signature is not valid
TPM_RC_KEY	RC_FMT1 + 0x01C	key fields are not compatible with the selected use
TPM_RC_POLICY_FAIL	RC_FMT1 + 0x01D	a policy check failed
TPM_RC_INTEGRITY	RC_FMT1 + 0x01F	integrity check failed
TPM_RC_TICKET	RC_FMT1 + 0x020	invalid ticket
TPM_RC_RESERVED_BITS	RC_FMT1 + 0x021	reserved bits not set to zero as required
TPM_RC_BAD_AUTH	RC_FMT1 + 0x022	authorization failure without DA implications
TPM_RC_EXPIRED	RC_FMT1 + 0x023	the policy has expired
TPM_RC_POLICY_CC	RC_FMT1 + 0x024	the *commandCode* in the policy is not the *commandCode* of the command or the command code in a policy command references a command that is not implemented
TPM_RC_BINDING	RC_FMT1 + 0x025	public and sensitive portions of an object are not cryptographically bound
TPM_RC_CURVE	RC_FMT1 + 0x026	curve not supported
TPM_RC_ECC_POINT	RC_FMT1 + 0x027	point is not on the required curve.
		New Subsection
RC_WARN	0x900	set for warning response codes

 Copyright © TCG 2006-2020

Name	Value	Description
TPM_RC_CONTEXT_GAP	RC_WARN + 0x001	gap for context ID is too large
TPM_RC_OBJECT_MEMORY	RC_WARN + 0x002	out of memory for object contexts
TPM_RC_SESSION_MEMORY	RC_WARN + 0x003	out of memory for session contexts
TPM_RC_MEMORY	RC_WARN + 0x004	out of shared object/session memory or need space for internal operations
TPM_RC_SESSION_HANDLES	RC_WARN + 0x005	out of session handles – a session must be flushed before a new session may be created
TPM_RC_OBJECT_HANDLES	RC_WARN + 0x006	out of object handles – the handle space for objects is depleted and a reboot is required NOTE 1 This cannot occur on the reference implementation. NOTE 2 There is no reason why an implementation would implement a design that would deplete handle space. Platform specifications are encouraged to forbid it.
TPM_RC_LOCALITY	RC_WARN + 0x007	bad locality
TPM_RC_YIELDED	RC_WARN + 0x008	the TPM has suspended operation on the command; forward progress was made and the command may be retried See TPM 2.0 Part 1, “Multi-tasking.” NOTE This cannot occur on the reference implementation.
TPM_RC_CANCELED	RC_WARN + 0x009	the command was canceled
TPM_RC_TESTING	RC_WARN + 0x00A	TPM is performing self-tests
TPM_RC_REFERENCE_H0	RC_WARN + 0x010	the 1st handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H1	RC_WARN + 0x011	the 2nd handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H2	RC_WARN + 0x012	the 3rd handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H3	RC_WARN + 0x013	the 4th handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H4	RC_WARN + 0x014	the 5th handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H5	RC_WARN + 0x015	the 6th handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_H6	RC_WARN + 0x016	the 7th handle in the handle area references a transient object or session that is not loaded
TPM_RC_REFERENCE_S0	RC_WARN + 0x018	the 1st authorization session handle references a session that is not loaded
TPM_RC_REFERENCE_S1	RC_WARN + 0x019	the 2nd authorization session handle references a session that is not loaded
TPM_RC_REFERENCE_S2	RC_WARN + 0x01A	the 3rd authorization session handle references a session that is not loaded
TPM_RC_REFERENCE_S3	RC_WARN + 0x01B	the 4th authorization session handle references a session that is not loaded
TPM_RC_REFERENCE_S4	RC_WARN + 0x01C	the 5th session handle references a session that is not loaded

 Copyright © TCG 2006-2020

Name	Value	Description
TPM_RC_REFERENCE_S5	RC_WARN + 0x01D	the 6th session handle references a session that is not loaded
TPM_RC_REFERENCE_S6	RC_WARN + 0x01E	the 7th authorization session handle references a session that is not loaded
TPM_RC_NV_RATE	RC_WARN + 0x020	the TPM is rate-limiting accesses to prevent wearout of NV
TPM_RC_LOCKOUT	RC_WARN + 0x021	authorizations for objects subject to DA protection are not allowed at this time because the TPM is in DA lockout mode
TPM_RC_RETRY	RC_WARN + 0x022	the TPM was not able to start the command
TPM_RC_NV_UNAVAILABLE	RC_WARN + 0x023	the command may require writing of NV and NV is not current accessible
TPM_RC_NOT_USED	RC_WARN + 0x7F	this value is reserved and shall not be returned by the TPM
		Additional Defines
TPM_RC_H	0x000	add to a handle-related error
TPM_RC_P	0x040	add to a parameter-related error
TPM_RC_S	0x800	add to a session-related error
TPM_RC_1	0x100	add to a parameter-, handle-, or session-related error
TPM_RC_2	0x200	add to a parameter-, handle-, or session-related error
TPM_RC_3	0x300	add to a parameter-, handle-, or session-related error
TPM_RC_4	0x400	add to a parameter-, handle-, or session-related error
TPM_RC_5	0x500	add to a parameter-, handle-, or session-related error
TPM_RC_6	0x600	add to a parameter-, handle-, or session-related error
TPM_RC_7	0x700	add to a parameter-, handle-, or session-related error
TPM_RC_8	0x800	add to a parameter-related error
TPM_RC_9	0x900	add to a parameter-related error
TPM_RC_A	0xA00	add to a parameter-related error
TPM_RC_B	0xB00	add to a parameter-related error
TPM_RC_C	0xC00	add to a parameter-related error
TPM_RC_D	0xD00	add to a parameter-related error
TPM_RC_E	0xE00	add to a parameter-related error
TPM_RC_F	0xF00	add to a parameter-related error
TPM_RC_N_MASK	0xF00	number mask

6.7 TPM_CLOCK_ADJUST

A TPM_CLOCK_ADJUST value is used to change the rate at which the TPM internal oscillator is divided. A change to the divider will change the rate at which *Clock* and *Time* change.

NOTE The recommended adjustments are approximately 1% for a course adjustment, 0.1% for a medium adjustment, and the minimum possible on the implementation for the fine adjustment (e.g., one count of the pre-scalar if possible).

Table 17 — Definition of (INT8) TPM_CLOCK_ADJUST Constants <IN>

Name	Value	Comments
TPM_CLOCK_COARSE_SLOWER	-3	Slow the *Clock* update rate by one coarse adjustment step.
TPM_CLOCK_MEDIUM_SLOWER	-2	Slow the *Clock* update rate by one medium adjustment step.
TPM_CLOCK_FINE_SLOWER	-1	Slow the *Clock* update rate by one fine adjustment step.
TPM_CLOCK_NO_CHANGE	0	No change to the *Clock* update rate.
TPM_CLOCK_FINE_FASTER	1	Speed the *Clock* update rate by one fine adjustment step.
TPM_CLOCK_MEDIUM_FASTER	2	Speed the *Clock* update rate by one medium adjustment step.
TPM_CLOCK_COARSE_FASTER	3	Speed the *Clock* update rate by one coarse adjustment step.
#TPM_RC_VALUE		

6.8 TPM_EO (EA Arithmetic Operands)

Table 18 — Definition of (UINT16) TPM_EO Constants <IN/OUT>

Operation Name	Value	Comments
TPM_EO_EQ	0x0000	A = B
TPM_EO_NEQ	0x0001	A ≠ B
TPM_EO_SIGNED_GT	0x0002	A > B signed
TPM_EO_UNSIGNED_GT	0x0003	A > B unsigned
TPM_EO_SIGNED_LT	0x0004	A < B signed
TPM_EO_UNSIGNED_LT	0x0005	A < B unsigned
TPM_EO_SIGNED_GE	0x0006	A ≥ B signed
TPM_EO_UNSIGNED_GE	0x0007	A ≥ B unsigned
TPM_EO_SIGNED_LE	0x0008	A ≤ B signed
TPM_EO_UNSIGNED_LE	0x0009	A ≤ B unsigned
TPM_EO_BITSET	0x000A	All bits SET in B are SET in A. ((A&B)=B)
TPM_EO_BITCLEAR	0x000B	All bits SET in B are CLEAR in A. ((A&B)=0)
#TPM_RC_VALUE		Response code returned when unmarshaling of this type fails

 Copyright © TCG 2006-2020

6.9 TPM_ST (Structure Tags)

Structure tags are used to disambiguate structures. They are 16-bit values with the most significant bit SET so that they do not overlap TPM_ALG_ID values. A single exception is made for the value associated with TPM_ST_RSP_COMMAND (0x00C4), which has the same value as the TPM_TAG_RSP_COMMAND tag from earlier versions of this specification. This value is used when the TPM is compatible with a previous TPM specification and the TPM cannot determine which family of response code to return because the command tag is not valid.

Many of the structures defined in this document have parameters that are unions of other structures. That is, a parameter may be one of several structures. The parameter will have a selector value that indicates which of the options is actually present.

In order to allow the marshaling and unmarshaling code to determine which of the possible structures is allowed, each selector will have a unique interface type and will constrain the number of possible tag values.

Table 19 defines the structure tags values. The definition of many structures is context-sensitive using an algorithm ID. In cases where an algorithm ID is not a meaningful way to designate the structure, the values in this table are used.

 Copyright © TCG 2006-2020

Table 19 — Definition of (UINT16) TPM_ST Constants <IN/OUT, S>

Name	Value	Comments
TPM_ST_RSP_COMMAND	0x00C4	*tag* value for a response; used when there is an error in the tag. This is also the value returned from a TPM 1.2 when an error occurs. This value is used in this specification because an error in the command tag may prevent determination of the family. When this tag is used in the response, the response code will be TPM_RC_BAD_TAG (0 $1E_{16}$), which has the same numeric value as the TPM 1.2 response code for TPM_BADTAG. NOTE In a previously published version of this specification, TPM_RC_BAD_TAG was incorrectly assigned a value of 0x030 instead of 30 (0x01e). Some implementations my return the old value instead of the new value.
TPM_ST_NULL	0X8000	no structure type specified
TPM_ST_NO_SESSIONS	0x8001	*tag* value for a command/response for a command defined in this specification; indicating that the command/response has no attached sessions and no *authorizationSize*/*parameterSize* value is present If the *responseCode* from the TPM is not TPM_RC_SUCCESS, then the response tag shall have this value.
TPM_ST_SESSIONS	0x8002	*tag* value for a command/response for a command defined in this specification; indicating that the command/response has one or more attached sessions and the *authorizationSize*/*parameterSize* field is present
reserved	0x8003	When used between application software and the TPM resource manager, this tag indicates that the command has no sessions and the handles are using the Name format rather than the 32-bit handle format. NOTE 1 The response to application software will have a *tag* of TPM_ST_NO_SESSIONS. Between the TRM and TPM, this tag would occur in a response from a TPM that overlaps the *tag* parameter of a request with the *tag* parameter of a response, when the response has no associated sessions. NOTE 2 This tag is not used by all TPM or TRM implementations.
reserved	0x8004	When used between application software and the TPM resource manager, this tag indicates that the command has sessions and the handles are using the Name format rather than the 32-bit handle format. NOTE 1 If the command completes successfully, the response to application software will have a *tag* of TPM_ST_SESSIONS. Between the TRM and TPM, would occur in a response from a TPM that overlaps the *tag* parameter of a request with the *tag* parameter of a response, when the response has authorization sessions. NOTE 2 This tag is not used by all TPM or TRM implementations.
TPM_ST_ATTEST_NV	0x8014	tag for an attestation structure
TPM_ST_ATTEST_COMMAND_AUDIT	0x8015	tag for an attestation structure
TPM_ST_ATTEST_SESSION_AUDIT	0x8016	tag for an attestation structure

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

Name	Value	Comments
TPM_ST_ATTEST_CERTIFY	0x8017	tag for an attestation structure
TPM_ST_ATTEST_QUOTE	0x8018	tag for an attestation structure
TPM_ST_ATTEST_TIME	0x8019	tag for an attestation structure
TPM_ST_ATTEST_CREATION	0x801A	tag for an attestation structure
reserved	0x801B	do not use NOTE This was previously assigned to TPM_ST_ATTEST_NV. The tag is changed because the structure has changed
TPM_ST_ATTEST_NV_DIGEST	0x801C	tag for an attestation structure
TPM_ST_CREATION	0x8021	tag for a ticket type
TPM_ST_VERIFIED	0x8022	tag for a ticket type
TPM_ST_AUTH_SECRET	0x8023	tag for a ticket type
TPM_ST_HASHCHECK	0x8024	tag for a ticket type
TPM_ST_AUTH_SIGNED	0x8025	tag for a ticket type
TPM_ST_FU_MANIFEST	0x8029	tag for a structure describing a Field Upgrade Policy

6.10 TPM_SU (Startup Type)

These values are used in TPM2_Startup() to indicate the shutdown and startup mode. The defined startup sequences are:

a) TPM Reset – Two cases:
    1) Shutdown(CLEAR) followed by Startup(CLEAR)
    2) Startup(CLEAR) with no Shutdown()
b) TPM Restart – Shutdown(STATE) followed by Startup(CLEAR)
c) TPM Resume – Shutdown(STATE) followed by Startup(STATE)

TPM_SU values of 80 00_{16} and above are reserved for internal use of the TPM and may not be assigned values.

NOTE In the reference code, a value of FF FF_{16} indicates that the startup state has not been set. If this was defined in this table to be, say, TPM_SU_NONE, then TPM_SU_NONE would be a valid input value but the caller is not allowed to indicate the that the startup type is TPM_SU_NONE so the reserved value is defined in the implementation as required for internal TPM uses.

 Copyright © TCG 2006-2020

Table 20 — Definition of (UINT16) TPM_SU Constants <IN>

Name	Value	Description
TPM_SU_CLEAR	0x0000	on TPM2_Shutdown(), indicates that the TPM should prepare for loss of power and save state required for an orderly startup (TPM Reset). on TPM2_Startup(), indicates that the TPM should perform TPM Reset or TPM Restart
TPM_SU_STATE	0x0001	on TPM2_Shutdown(), indicates that the TPM should prepare for loss of power and save state required for an orderly startup (TPM Restart or TPM Resume) on TPM2_Startup(), indicates that the TPM should restore the state saved by TPM2_Shutdown(TPM_SU_STATE)
#TPM_RC_VALUE		response code when incorrect value is used

6.11 TPM_SE (Session Type)

This type is used in TPM2_StartAuthSession() to indicate the type of the session to be created.

Table 21 — Definition of (UINT8) TPM_SE Constants <IN>

Name	Value	Description
TPM_SE_HMAC	0x00	
TPM_SE_POLICY	0x01	
TPM_SE_TRIAL	0x03	The policy session is being used to compute the *policyHash* and not for command authorization. This setting modifies some policy commands and prevents session from being used to authorize a command.
#TPM_RC_VALUE		response code when incorrect value is used

 Copyright © TCG 2006-2020

6.12 TPM_CAP (Capabilities)

The TPM_CAP values are used in TPM2_GetCapability() to select the type of the value to be returned. The format of the response varies according to the type of the value.

Table 22 — Definition of (UINT32) TPM_CAP Constants

Capability Name	Value	Property Type	Return Type
TPM_CAP_FIRST	0x00000000		
TPM_CAP_ALGS	0x00000000	TPM_ALG_ID(1)	TPML_ALG_PROPERTY
TPM_CAP_HANDLES	0x00000001	TPM_HANDLE	TPML_HANDLE
TPM_CAP_COMMANDS	0x00000002	TPM_CC	TPML_CCA
TPM_CAP_PP_COMMANDS	0x00000003	TPM_CC	TPML_CC
TPM_CAP_AUDIT_COMMANDS	0x00000004	TPM_CC	TPML_CC
TPM_CAP_PCRS	0x00000005	reserved	TPML_PCR_SELECTION
TPM_CAP_TPM_PROPERTIES	0x00000006	TPM_PT	TPML_TAGGED_TPM_PROPERTY
TPM_CAP_PCR_PROPERTIES	0x00000007	TPM_PT_PCR	TPML_TAGGED_PCR_PROPERTY
TPM_CAP_ECC_CURVES	0x00000008	TPM_ECC_CURVE(1)	TPML_ECC_CURVE
TPM_CAP_AUTH_POLICIES	0x00000009	TPM_HANDLE(2)(3)	TPML_TAGGED_POLICY
TPM_CAP_ACT	0x0000000A	TPM_HANDLE(2(4))	TPML_ACT_DATA
TPM_CAP_LAST	0x0000000A		
TPM_CAP_VENDOR_PROPERTY	0x00000100	manufacturer specific	manufacturer-specific values
#TPM_RC_VALUE			

NOTES:
(1) The TPM_ALG_ID or TPM_ECC_CURVE is cast to a UINT32
(2) The TPM will return TPM_RC_VALUE if the handle does not reference the range for permanent handles.
(3) TPM_CAP_AUTH_POLICIES was added in revision 01.32.
(4) TPM_CAP_ACT was added in revision 01.57.

 Copyright © TCG 2006-2020

6.13 TPM_PT (Property Tag)

The TPM_PT constants are used in TPM2_GetCapability(capability = TPM_CAP_TPM_PROPERTIES) to indicate the property being selected or returned.

The values in the fixed group (PT_FIXED) are not changeable through programmatic means other than a firmware update. The values in the variable group (PT_VAR) may be changed with TPM commands but should be persistent over power cycles and only changed when indicated by the detailed actions code.

Table 23 — Definition of (UINT32) TPM_PT Constants <IN/OUT, S>

Capability Name	Value	Comments
TPM_PT_NONE	0x00000000	indicates no property type
PT_GROUP	0x00000100	The number of properties in each group. NOTE The first group with any properties is group 1 (PT_GROUP * 1). Group 0 is reserved.
PT_FIXED	PT_GROUP * 1	the group of fixed properties returned as TPMS_TAGGED_PROPERTY The values in this group are only changed due to a firmware change in the TPM.
TPM_PT_FAMILY_INDICATOR	PT_FIXED + 0	a 4-octet character string containing the TPM Family value (TPM_SPEC_FAMILY)
TPM_PT_LEVEL	PT_FIXED + 1	the level of the specification NOTE 1 For this specification, the level is zero. NOTE 2 The level is on the title page of the specification.
TPM_PT_REVISION	PT_FIXED + 2	the specification Revision times 100 EXAMPLE Revision 01.01 would have a value of 101. NOTE The Revision value is on the title page of the specification.
TPM_PT_DAY_OF_YEAR	PT_FIXED + 3	the specification day of year using TCG calendar EXAMPLE November 15, 2010, has a day of year value of 319 (00 00 01 $3F_{16}$). NOTE The specification date is on the title page of the specification or errata (see 6.1).
TPM_PT_YEAR	PT_FIXED + 4	the specification year using the CE EXAMPLE The year 2010 has a value of 00 00 07 DA_{16}. NOTE The specification date is on the title page of the specification or errata (see 6.1).
TPM_PT_MANUFACTURER	PT_FIXED + 5	the vendor ID unique to each TPM manufacturer
TPM_PT_VENDOR_STRING_1	PT_FIXED + 6	the first four characters of the vendor ID string NOTE When the vendor string is fewer than 16 octets, the additional property values do not have to be present. A vendor string of 4 octets can be represented in one 32-bit value and no null terminating character is required.
TPM_PT_VENDOR_STRING_2	PT_FIXED + 7	the second four characters of the vendor ID string
TPM_PT_VENDOR_STRING_3	PT_FIXED + 8	the third four characters of the vendor ID string
TPM_PT_VENDOR_STRING_4	PT_FIXED + 9	the fourth four characters of the vendor ID sting
TPM_PT_VENDOR_TPM_TYPE	PT_FIXED + 10	vendor-defined value indicating the TPM model
TPM_PT_FIRMWARE_VERSION_1	PT_FIXED + 11	the most-significant 32 bits of a TPM vendor-specific value indicating the version number of the firmware. See 10.12.2 and 10.12.12.

 Copyright © TCG 2006-2020

Capability Name	Value	Comments
TPM_PT_FIRMWARE_VERSION_2	PT_FIXED + 12	the least-significant 32 bits of a TPM vendor-specific value indicating the version number of the firmware. See 10.12.2 and 10.12.12.
TPM_PT_INPUT_BUFFER	PT_FIXED + 13	the maximum size of a parameter (typically, a TPM2B_MAX_BUFFER)
TPM_PT_HR_TRANSIENT_MIN	PT_FIXED + 14	the minimum number of transient objects that can be held in TPM RAM NOTE This minimum shall be no less than the minimum value required by the platform-specific specification to which the TPM is built.
TPM_PT_HR_PERSISTENT_MIN	PT_FIXED + 15	the minimum number of persistent objects that can be held in TPM NV memory NOTE This minimum shall be no less than the minimum value required by the platform-specific specification to which the TPM is built.
TPM_PT_HR_LOADED_MIN	PT_FIXED + 16	the minimum number of authorization sessions that can be held in TPM RAM NOTE This minimum shall be no less than the minimum value required by the platform-specific specification to which the TPM is built.
TPM_PT_ACTIVE_SESSIONS_MAX	PT_FIXED + 17	the number of authorization sessions that may be active at a time A session is active when it has a context associated with its handle. The context may either be in TPM RAM or be context saved. NOTE This value shall be no less than the minimum value required by the platform-specific specification to which the TPM is built.
TPM_PT_PCR_COUNT	PT_FIXED + 18	the number of PCR implemented NOTE This number is determined by the defined attributes, not the number of PCR that are populated.
TPM_PT_PCR_SELECT_MIN	PT_FIXED + 19	the minimum number of octets in a TPMS_PCR_SELECT.*sizeOfSelect* NOTE This value is not determined by the number of PCR implemented but by the number of PCR required by the platform-specific specification with which the TPM is compliant or by the implementer if not adhering to a platform-specific specification.
TPM_PT_CONTEXT_GAP_MAX	PT_FIXED + 20	the maximum allowed difference (unsigned) between the *contextID* values of two saved session contexts This value shall be 2^n-1, where n is at least 16.
	PT_FIXED + 21	skipped
TPM_PT_NV_COUNTERS_MAX	PT_FIXED + 22	the maximum number of NV Indexes that are allowed to have the TPM_NT_COUNTER attribute NOTE 1 It is allowed for this value to be larger than the number of NV Indexes that can be defined. This would be indicative of a TPM implementation that did not use different implementation technology for different NV Index types. NOTE 2 The value zero indicates that there is no fixed maximum. The number of counter indexes is determined by the available NV memory pool.
TPM_PT_NV_INDEX_MAX	PT_FIXED + 23	the maximum size of an NV Index data area

 Copyright © TCG 2006-2020

Capability Name	Value	Comments
TPM_PT_MEMORY	PT_FIXED + 24	a TPMA_MEMORY indicating the memory management method for the TPM
TPM_PT_CLOCK_UPDATE	PT_FIXED + 25	interval, in milliseconds, between updates to the copy of TPMS_CLOCK_INFO.*clock* in NV
TPM_PT_CONTEXT_HASH	PT_FIXED + 26	the algorithm used for the integrity HMAC on saved contexts and for hashing the *fuData* of TPM2_FirmwareRead()
TPM_PT_CONTEXT_SYM	PT_FIXED + 27	TPM_ALG_ID, the algorithm used for encryption of saved contexts
TPM_PT_CONTEXT_SYM_SIZE	PT_FIXED + 28	TPM_KEY_BITS, the size of the key used for encryption of saved contexts
TPM_PT_ORDERLY_COUNT	PT_FIXED + 29	the modulus - 1 of the count for NV update of an orderly counter The returned value is MAX_ORDERLY_COUNT. This will have a value of $2^N – 1$ where $1 \le N \le 32$ NOTE 1 An “orderly counter” is an NV Index with an TPM_NT of TPM_NV_COUNTER and TPMA_NV_ORDERLY SET. NOTE 2 When the low-order bits of a counter equal this value, an NV write occurs on the next increment.
TPM_PT_MAX_COMMAND_SIZE	PT_FIXED + 30	the maximum value for *commandSize* in a command
TPM_PT_MAX_RESPONSE_SIZE	PT_FIXED + 31	the maximum value for *responseSize* in a response
TPM_PT_MAX_DIGEST	PT_FIXED + 32	the maximum size of a digest that can be produced by the TPM
TPM_PT_MAX_OBJECT_CONTEXT	PT_FIXED + 33	the maximum size of an object context that will be returned by TPM2_ContextSave
TPM_PT_MAX_SESSION_CONTEXT	PT_FIXED + 34	the maximum size of a session context that will be returned by TPM2_ContextSave
TPM_PT_PS_FAMILY_INDICATOR	PT_FIXED + 35	platform-specific family (a TPM_PS value)(see Table 25) NOTE The platform-specific values for the TPM_PT_PS parameters are in the relevant platform-specific specification. In the reference implementation, all of these values are 0.
TPM_PT_PS_LEVEL	PT_FIXED + 36	the level of the platform-specific specification
TPM_PT_PS_REVISION	PT_FIXED + 37	a platform specific value
TPM_PT_PS_DAY_OF_YEAR	PT_FIXED + 38	the platform-specific TPM specification day of year using TCG calendar EXAMPLE November 15, 2010, has a day of year value of 319 (00 00 01 $3F_{16}$).
TPM_PT_PS_YEAR	PT_FIXED + 39	the platform-specific TPM specification year using the CE EXAMPLE The year 2010 has a value of 00 00 07 DA_{16}.
TPM_PT_SPLIT_MAX	PT_FIXED + 40	the number of split signing operations supported by the TPM
TPM_PT_TOTAL_COMMANDS	PT_FIXED + 41	total number of commands implemented in the TPM
TPM_PT_LIBRARY_COMMANDS	PT_FIXED + 42	number of commands from the TPM library that are implemented
TPM_PT_VENDOR_COMMANDS	PT_FIXED + 43	number of vendor commands that are implemented
TPM_PT_NV_BUFFER_MAX	PT_FIXED + 44	the maximum data size in one NV write, NV read, NV extend, or NV certify command

 Copyright © TCG 2006-2020

Capability Name	Value	Comments
TPM_PT_MODES	PT_FIXED + 45	a TPMA_MODES value, indicating that the TPM is designed for these modes.
TPM_PT_MAX_CAP_BUFFER	PT_FIXED + 46	the maximum size of a TPMS_CAPABILITY_DATA structure returned in TPM2_GetCapability().
		Intentionally left empty
PT_VAR	PT_GROUP * 2	the group of variable properties returned as TPMS_TAGGED_PROPERTY The properties in this group change because of a Protected Capability other than a firmware update. The values are not necessarily persistent across all power transitions.
TPM_PT_PERMANENT	PT_VAR + 0	TPMA_PERMANENT
TPM_PT_STARTUP_CLEAR	PT_VAR + 1	TPMA_STARTUP_CLEAR
TPM_PT_HR_NV_INDEX	PT_VAR + 2	the number of NV Indexes currently defined
TPM_PT_HR_LOADED	PT_VAR + 3	the number of authorization sessions currently loaded into TPM RAM
TPM_PT_HR_LOADED_AVAIL	PT_VAR + 4	the number of additional authorization sessions, of any type, that could be loaded into TPM RAM This value is an estimate. If this value is at least 1, then at least one authorization session of any type may be loaded. Any command that changes the RAM memory allocation can make this estimate invalid. NOTE A valid implementation may return 1 even if more than one authorization session would fit into RAM.
TPM_PT_HR_ACTIVE	PT_VAR + 5	the number of active authorization sessions currently being tracked by the TPM This is the sum of the loaded and saved sessions.
TPM_PT_HR_ACTIVE_AVAIL	PT_VAR + 6	the number of additional authorization sessions, of any type, that could be created This value is an estimate. If this value is at least 1, then at least one authorization session of any type may be created. Any command that changes the RAM memory allocation can make this estimate invalid. NOTE A valid implementation may return 1 even if more than one authorization session could be created.
TPM_PT_HR_TRANSIENT_AVAIL	PT_VAR + 7	estimate of the number of additional transient objects that could be loaded into TPM RAM This value is an estimate. If this value is at least 1, then at least one object of any type may be loaded. Any command that changes the memory allocation can make this estimate invalid. NOTE A valid implementation may return 1 even if more than one transient object would fit into RAM.
TPM_PT_HR_PERSISTENT	PT_VAR + 8	the number of persistent objects currently loaded into TPM NV memory

 Copyright © TCG 2006-2020

Capability Name	Value	Comments
TPM_PT_HR_PERSISTENT_AVAIL	PT_VAR + 9	the number of additional persistent objects that could be loaded into NV memory This value is an estimate. If this value is at least 1, then at least one object of any type may be made persistent. Any command that changes the NV memory allocation can make this estimate invalid. NOTE A valid implementation may return 1 even if more than one persistent object would fit into NV memory.
TPM_PT_NV_COUNTERS	PT_VAR + 10	the number of defined NV Indexes that have NV the TPM_NT_COUNTER attribute
TPM_PT_NV_COUNTERS_AVAIL	PT_VAR + 11	the number of additional NV Indexes that can be defined with their TPM_NT of TPM_NV_COUNTER and the TPMA_NV_ORDERLY attribute SET This value is an estimate. If this value is at least 1, then at least one NV Index may be created with a TPM_NT of TPM_NV_COUNTER and the TPMA_NV_ORDERLY attributes. Any command that changes the NV memory allocation can make this estimate invalid. NOTE A valid implementation may return 1 even if more than one NV counter could be defined.
TPM_PT_ALGORITHM_SET	PT_VAR + 12	code that limits the algorithms that may be used with the TPM
TPM_PT_LOADED_CURVES	PT_VAR + 13	the number of loaded ECC curves
TPM_PT_LOCKOUT_COUNTER	PT_VAR + 14	the current value of the lockout counter (*failedTries*)
TPM_PT_MAX_AUTH_FAIL	PT_VAR + 15	the number of authorization failures before DA lockout is invoked
TPM_PT_LOCKOUT_INTERVAL	PT_VAR + 16	the number of seconds before the value reported by TPM_PT_LOCKOUT_COUNTER is decremented
TPM_PT_LOCKOUT_RECOVERY	PT_VAR + 17	the number of seconds after a lockoutAuth failure before use of lockoutAuth may be attempted again
TPM_PT_NV_WRITE_RECOVERY	PT_VAR + 18	number of milliseconds before the TPM will accept another command that will modify NV This value is an approximation and may go up or down over time.
TPM_PT_AUDIT_COUNTER_0	PT_VAR + 19	the high-order 32 bits of the command audit counter
TPM_PT_AUDIT_COUNTER_1	PT_VAR + 20	the low-order 32 bits of the command audit counter

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

6.14 TPM_PT_PCR (PCR Property Tag)

The TPM_PT_PCR constants are used in TPM2_GetCapability() to indicate the property being selected or returned. The PCR properties can be read when *capability* == TPM_CAP_PCR_PROPERTIES. If there is no property that corresponds to the value of *property*, the next higher value is returned, if it exists.

Table 24 — Definition of (UINT32) TPM_PT_PCR Constants <IN/OUT, S>

Capability Name	Value	Comments
TPM_PT_PCR_FIRST	0x00000000	bottom of the range of TPM_PT_PCR properties
TPM_PT_PCR_SAVE	0x00000000	a SET bit in the TPMS_PCR_SELECT indicates that the PCR is saved and restored by TPM_SU_STATE
TPM_PT_PCR_EXTEND_L0	0x00000001	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be extended from locality 0 This property is only present if a locality other than 0 is implemented.
TPM_PT_PCR_RESET_L0	0x00000002	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be reset by TPM2_PCR_Reset() from locality 0
TPM_PT_PCR_EXTEND_L1	0x00000003	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be extended from locality 1 This property is only present if locality 1 is implemented.
TPM_PT_PCR_RESET_L1	0x00000004	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be reset by TPM2_PCR_Reset() from locality 1 This property is only present if locality 1 is implemented.
TPM_PT_PCR_EXTEND_L2	0x00000005	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be extended from locality 2 This property is only present if localities 1 and 2 are implemented.
TPM_PT_PCR_RESET_L2	0x00000006	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be reset by TPM2_PCR_Reset() from locality 2 This property is only present if localities 1 and 2 are implemented.
TPM_PT_PCR_EXTEND_L3	0x00000007	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be extended from locality 3 This property is only present if localities 1, 2, and 3 are implemented.
TPM_PT_PCR_RESET_L3	0x00000008	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be reset by TPM2_PCR_Reset() from locality 3 This property is only present if localities 1, 2, and 3 are implemented.
TPM_PT_PCR_EXTEND_L4	0x00000009	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be extended from locality 4 This property is only present if localities 1, 2, 3, and 4 are implemented.
TPM_PT_PCR_RESET_L4	0x0000000A	a SET bit in the TPMS_PCR_SELECT indicates that the PCR may be reset by TPM2_PCR_Reset() from locality 4 This property is only present if localities 1, 2, 3, and 4 are implemented.

 Copyright © TCG 2006-2020

Capability Name	Value	Comments
reserved	0x0000000B – 0x00000010	the values in this range are reserved They correspond to values that may be used to describe attributes associated with the extended localities (32-255).synthesize additional software localities. The meaning of these properties need not be the same as the meaning for the Extend and Reset properties above.
TPM_PT_PCR_NO_INCREMENT	0x00000011	a SET bit in the TPMS_PCR_SELECT indicates that modifications to this PCR (reset or Extend) will not increment the *pcrUpdateCounter*
TPM_PT_PCR_DRTM_RESET	0x00000012	a SET bit in the TPMS_PCR_SELECT indicates that the PCR is reset by a D-RTM event These PCR are reset to -1 on TPM2_Startup() and reset to 0 on a _TPM_Hash_End event following a _TPM_Hash_Start event.
TPM_PT_PCR_POLICY	0x00000013	a SET bit in the TPMS_PCR_SELECT indicates that the PCR is controlled by policy This property is only present if the TPM supports policy control of a PCR.
TPM_PT_PCR_AUTH	0x00000014	a SET bit in the TPMS_PCR_SELECT indicates that the PCR is controlled by an authorization value This property is only present if the TPM supports authorization control of a PCR.
reserved	0x00000015	reserved for the next (2nd) TPM_PT_PCR_POLICY set
reserved	0x00000016	reserved for the next (2nd) TPM_PT_PCR_AUTH set
reserved	0x00000017 – 0x00000210	reserved for the 2nd through 255th TPM_PT_PCR_POLICY and TPM_PT_PCR_AUTH values
reserved	0x00000211	reserved to the 256th, and highest allowed, TPM_PT_PCR_POLICY set
reserved	0x00000212	reserved to the 256th, and highest allowed, TPM_PT_PCR_AUTH set
reserved	0x00000213	new PCR property values may be assigned starting with this value
TPM_PT_PCR_LAST	0x00000014	top of the range of TPM_PT_PCR properties of the implementation If the TPM receives a request for a PCR property with a value larger than this, the TPM will return a zero length list and set the *moreData* parameter to NO. NOTE This is an implementation-specific value. The value shown reflects the reference code implementation.

7 Handles

7.1 Introduction

Handles are 32-bit values used to reference shielded locations of various types within the TPM.

Table 26 — Definition of Types for Handles

Type	Name	Description
UINT32	TPM_HANDLE	

Handles may refer to objects (keys or data blobs), authorization sessions (HMAC and policy), NV Indexes, permanent TPM locations, and PCR.

7.2 TPM_HT (Handle Types)

The 32-bit handle space is divided into 256 regions of equal size with 2^{24} values in each. Each of these ranges represents a handle type.

The type of the entity is indicated by the MSO of its handle. The values for the MSO and the entity referenced are shown in Table 27.

Table 27 — Definition of (UINT8) TPM_HT Constants <S>

Name	Value	Comments
TPM_HT_PCR	0x00	**PCR** – consecutive numbers, starting at 0, that reference the PCR registers A platform-specific specification will set the minimum number of PCR and an implementation may have more.
TPM_HT_NV_INDEX	0x01	**NV Index** – assigned by the caller
TPM_HT_HMAC_SESSION	0x02	**HMAC Authorization Session** – assigned by the TPM when the session is created
TPM_HT_LOADED_SESSION	0x02	**Loaded Authorization Session** – used only in the context of TPM2_GetCapability This type references both loaded HMAC and loaded policy authorization sessions.
TPM_HT_POLICY_SESSION	0x03	**Policy Authorization Session** – assigned by the TPM when the session is created
TPM_HT_SAVED_SESSION	0x03	**Saved Authorization Session** – used only in the context of TPM2_GetCapability This type references saved authorization session contexts for which the TPM is maintaining tracking information.
TPM_HT_PERMANENT	0x40	**Permanent Values** – assigned by this specification in Table 28
TPM_HT_TRANSIENT	0x80	**Transient Objects** – assigned by the TPM when an object is loaded into transient-object memory or when a persistent object is converted to a transient object
TPM_HT_PERSISTENT	0x81	**Persistent Objects** – assigned by the TPM when a loaded transient object is made persistent
TPM_HT_AC	0x90	**Attached Component** – handle for an Attached Component.

 Copyright © TCG 2006-2020

When a transient object is loaded, the TPM shall assign a handle with an MSO of TPM_HT_TRANSIENT. The object may be assigned a different handle each time it is loaded. The TPM shall ensure that handles assigned to transient objects are unique and assigned to only one transient object at a time.

EXAMPLE 1 If a TPM is only able to hold 4 transient objects in internal memory, it might choose to assign handles to those objects with the values 80 00 00 00_{16} – 80 00 00 03_{16}.

When a transient object is converted to a persistent object (TPM2_EvictControl()), the TPM shall validate that the handle provided by the caller has an MSO of TPM_HT_PERSISTENT and that the handle is not already assigned to a persistent object.

A handle is assigned to a session when the session is started. The handle shall have an MSO equal to TPM_HT_SESSION and remain associated with that session until the session is closed or flushed. The TPM shall ensure that a session handle is only associated with one session at a time. When the session is loaded into the TPM using TPM2_LoadContext(), it will have the same handle each time it is loaded.

EXAMPLE 2 If a TPM is only able to track 64 active sessions at a time, it could number those sessions using the values xx 00 01 00_{16} – xx 00 01 $3F_{16}$ where xx is either 02_{16} or 03_{16} depending on the session type.

7.3 Persistent Handle Sub-ranges

Persistent handles are assigned by the caller of TPM2_EvictControl(). Owner Authorization or Platform Authorization is required to authorize allocation of space for a persistent object. These entities are given separate ranges of persistent handles so that they do not have to allocate from a common range of handles.

NOTE While this “namespace” allocation of the handle ranges could have been handled by convention, TPM enforcement is used to prevent errors by the OS or malicious software from affecting the platform’s use of the NV memory.

The Owner is allocated persistent handles in the range of 81 00 00 00_{16} to 81 7F FF FF_{16} inclusive and the TPM will return an error if Owner Authorization is used to attempt to assign a persistent handle outside of this range.

November 8, 2019 **Copyright © TCG 2006-2020** Level 00 Revision 01.59

7.4 TPM_RH (Permanent Handles)

Table 28 lists the architecturally defined handles that cannot be changed. The handles include authorization handles, and special handles.

Table 28 — Definition of (TPM_HANDLE) TPM_RH Constants <S>

Name	Value	Type	Comments
TPM_RH_FIRST	0x40000000	R	
TPM_RH_SRK	0x40000000	R	not used[1]
TPM_RH_OWNER	0x40000001	K, A, P	handle references the Storage Primary Seed (SPS), the *ownerAuth*, and the *ownerPolicy*
TPM_RH_REVOKE	0x40000002	R	not used[1]
TPM_RH_TRANSPORT	0x40000003	R	not used[1]
TPM_RH_OPERATOR	0x40000004	R	not used[1]
TPM_RH_ADMIN	0x40000005	R	not used[1]
TPM_RH_EK	0x40000006	R	not used[1]
TPM_RH_NULL	0x40000007	K, A, P	a handle associated with the null hierarchy, an EmptyAuth *authValue*, and an Empty Policy *authPolicy*.
TPM_RH_UNASSIGNED	0x40000008	R	value reserved to the TPM to indicate a handle location that has not been initialized or assigned
TPM_RS_PW	0x40000009	S	authorization value used to indicate a password authorization session
TPM_RH_LOCKOUT	0x4000000A	A	references the authorization associated with the dictionary attack lockout reset
TPM_RH_ENDORSEMENT	0x4000000B	K, A, P	references the Endorsement Primary Seed (EPS), *endorsementAuth*, and *endorsementPolicy*
TPM_RH_PLATFORM	0x4000000C	K, A, P	references the Platform Primary Seed (PPS), *platformAuth*, and *platformPolicy*
TPM_RH_PLATFORM_NV	0x4000000D	C	for phEnableNV
TPM_RH_AUTH_00	0x40000010	A	Start of a range of authorization values that are vendor-specific. A TPM may support any of the values in this range as are needed for vendor-specific purposes. Disabled if ehEnable is CLEAR. NOTE “Any” includes “none”.
TPM_RH_AUTH_FF	0x4000010F	A	End of the range of vendor-specific authorization values.
TPM_RH_ACT_0	0x40000110	A,P	Start of the range of authenticated timers
TPM_RH_ACT_F	0x4000011F	A,P	End of the range of authenticated timers
TPM_RH_LAST	0x4000011F	R	the top of the reserved handle area This is set to allow TPM2_GetCapability() to know where to stop. It may vary as implementations add to the permanent handle area.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

Name	Value	Type	Comments
Type definitions: **R** – a reserved value **K** – a Primary Seed **A** – an authorization value **P** – a policy value **S** – a session handle **C** - a control Note 1 The handle is only used in a TPM that is compatible with a previous version of this specification. It is not used in any command defined in this version of the specification.			

7.5 TPM_HC (Handle Value Constants)

The definitions in Table 29 are used to define many of the interface data types.

These values, that indicate ranges, are informative and may be changed by an implementation. The TPM will always return the correct handle type as described in 7.2 Table 27:

- HMAC_SESSION_FIRST—HMAC_SESSION_LAST,
- LOADED_SESSION_FIRST—LOADED_SESSION_LAST,
- POLICY_SESSION_FIRST—POLICY_SESSION_LAST,
- TRANSIENT_FIRST—TRANSIENT_LAST,
- ACTIVE_SESSION_FIRST—ACTIVE_SESSION_LAST,
- PCR_FIRST—PCR_LAST

These values are input by the caller. The TPM implementation should support the entire range:

- PERSISTENT_FIRST—PERSISTENT_LAST,
- PLATFORM_PERSISTENT—PLATFORM_PERSISTENT+0x007FFFFF,
- NV_INDEX_FIRST—NV_INDEX_LAST,
- PERMANENT_FIRST—PERMANENT_LAST

NOTE PCR0 is architecturally defined to have a handle value of 0.

For the reference implementation, the handle range for sessions starts at the lowest allowed value for a session handle. The highest value for a session handle is determined by how many active sessions are allowed by the implementation. The MSO of the session handle will be set according to the session type.

A similar approach is used for transient objects with the first assigned handle at the bottom of the range defined by TPM_HT_TRANSIENT and the top of the range determined by the implementation-dependent value of MAX_LOADED_OBJECTS.

The first assigned handle for evict objects is also at the bottom of the allowed range defined by TPM_HT_PERSISTENT and the top of the range determined by the implementation-dependent value of MAX_EVICT_OBJECTS.

NOTE The values in Table 29 are intended to facilitate the process of making the handle larger than 32 bits in the future. It is intended that HR_MASK and HR_SHIFT are the only values that need change to resize the handle space.

 Copyright © TCG 2006-2020

Table 29 — Definition of (TPM_HANDLE) TPM_HC Constants <S>

Name	Value	Comments
HR_HANDLE_MASK	0x00FFFFFF	to mask off the HR
HR_RANGE_MASK	0xFF000000	to mask off the variable part
HR_SHIFT	24	
HR_PCR	(TPM_HT_PCR << HR_SHIFT)	
HR_HMAC_SESSION	(TPM_HT_HMAC_SESSION << HR_SHIFT)	
HR_POLICY_SESSION	(TPM_HT_POLICY_SESSION << HR_SHIFT)	
HR_TRANSIENT	(TPM_HT_TRANSIENT << HR_SHIFT)	
HR_PERSISTENT	(TPM_HT_PERSISTENT << HR_SHIFT)	
HR_NV_INDEX	(TPM_HT_NV_INDEX << HR_SHIFT)	
HR_PERMANENT	(TPM_HT_PERMANENT << HR_SHIFT)	
PCR_FIRST	(HR_PCR + 0)	first PCR
PCR_LAST	(PCR_FIRST + IMPLEMENTATION_PCR-1)	last PCR
HMAC_SESSION_FIRST	(HR_HMAC_SESSION + 0)	first HMAC session
HMAC_SESSION_LAST	(HMAC_SESSION_FIRST+MAX_ACTIVE_SESSIONS-1)	last HMAC session
LOADED_SESSION_FIRST	HMAC_SESSION_FIRST	used in GetCapability
LOADED_SESSION_LAST	HMAC_SESSION_LAST	used in GetCapability
POLICY_SESSION_FIRST	(HR_POLICY_SESSION + 0)	first policy session
POLICY_SESSION_LAST	(POLICY_SESSION_FIRST + MAX_ACTIVE_SESSIONS-1)	last policy session

8 Attribute Structures

8.1 Description

Attributes are expressed as bit fields of varying size. An attribute field structure may be 1, 2, or 4 octets in length.

The bit numbers for an attribute structure are assigned with the number 0 assigned to the least-significant bit of the structure and the highest number assigned to the most-significant bit of the structure.

The least significant bit is determined by treating the attribute structure as an integer. The least-significant bit would be the bit that is set when the value of the integer is 1.

When any reserved bit in an attribute is SET, the TPM shall return TPM_RC_RESERVED_BITS. This response code is not shown in the tables for attributes.

8.2 TPMA_ALGORITHM

This structure defines the attributes of an algorithm.

Each algorithm has a fundamental attribute: *asymmetric*, *symmetric*, or *hash*. In some cases (e.g., TPM_ALG_RSA or TPM_ALG_AES), this is the only attribute.

A mode, method, or scheme may have an associated asymmetric, symmetric, or hash algorithm.

NOTE A hash algorithm that can be used directly is one that has only the *hash* attribute SET.

EXAMPLE A PCR bank or an object Name can only use an algorithm that has only the *hash* attribute SET.

Table 30 — Definition of (UINT32) TPMA_ALGORITHM Bits

Bit	Name	Definition
0	asymmetric	**SET (1):** an asymmetric algorithm with public and private portions **CLEAR (0):** not an asymmetric algorithm
1	symmetric	**SET (1):** a symmetric block cipher **CLEAR (0):** not a symmetric block cipher
2	hash	**SET (1):** a hash algorithm **CLEAR (0):** not a hash algorithm
3	object	**SET (1):** an algorithm that may be used as an object type **CLEAR (0):** an algorithm that is not used as an object type
7:4	Reserved	
8	signing	**SET (1):** a signing algorithm. The setting of *asymmetric*, *symmetric*, and *hash* will indicate the type of signing algorithm. **CLEAR (0):** not a signing algorithm
9	encrypting	**SET (1):** an encryption/decryption algorithm. The setting of *asymmetric*, *symmetric*, and *hash* will indicate the type of encryption/decryption algorithm. **CLEAR (0):** not an encryption/decryption algorithm
10	method	**SET (1):** a method such as a key derivative function (KDF) **CLEAR (0):** not a method
31:11	Reserved	

 Copyright © TCG 2006-2020

8.3 TPMA_OBJECT (Object Attributes)

8.3.1 Introduction

This attribute structure indicates an object's use, its authorization types, and its relationship to other objects.

The state of the attributes is determined when the object is created and they are never changed by the TPM. Additionally, the setting of these structures is reflected in the integrity value of the private area of an object in order to allow the TPM to detect modifications of the Protected Object when stored off the TPM.

8.3.2 Structure Definition

Table 31 — Definition of (UINT32) TPMA_OBJECT Bits

Bit	Name	Definition
0	Reserved	shall be zero
1	fixedTPM	**SET (1):** The hierarchy of the object, as indicated by its Qualified Name, may not change. **CLEAR (0):** The hierarchy of the object may change as a result of this object or an ancestor key being duplicated for use in another hierarchy. NOTE *fixedTPM* does not indicate that key material resides on a single TPM (see *sensitiveDataOrigin*).
2	stClear	**SET (1):** Previously saved contexts of this object may not be loaded after Startup(CLEAR). **CLEAR (0):** Saved contexts of this object may be used after a Shutdown(STATE) and subsequent Startup().
3	Reserved	shall be zero
4	fixedParent	**SET (1):** The parent of the object may not change. **CLEAR (0):** The parent of the object may change as the result of a TPM2_Duplicate() of the object.
5	sensitiveDataOrigin	**SET (1):** Indicates that, when the object was created with TPM2_Create() or TPM2_CreatePrimary(), the TPM generated all of the sensitive data other than the *authValue*. **CLEAR (0):** A portion of the sensitive data, other than the *authValue*, was provided by the caller.
6	userWithAuth	**SET (1):** Approval of USER role actions with this object may be with an HMAC session or with a password using the *authValue* of the object or a policy session. **CLEAR (0):** Approval of USER role actions with this object may only be done with a policy session.
7	adminWithPolicy	**SET (1):** Approval of ADMIN role actions with this object may only be done with a policy session. **CLEAR (0):** Approval of ADMIN role actions with this object may be with an HMAC session or with a password using the *authValue* of the object or a policy session.
9:8	Reserved	shall be zero
10	noDA	**SET (1):** The object is not subject to dictionary attack protections. **CLEAR (0):** The object is subject to dictionary attack protections.

 Copyright © TCG 2006-2020

Bit	Name	Definition
11	encryptedDuplication	**SET (1):** If the object is duplicated, then *symmetricAlg* shall not be TPM_ALG_NULL and *newParentHandle* shall not be TPM_RH_NULL. **CLEAR (0):** The object may be duplicated without an inner wrapper on the private portion of the object and the new parent may be TPM_RH_NULL.
15:12	Reserved	shall be zero
16	restricted	**SET (1):** Key usage is restricted to manipulate structures of known format; the parent of this key shall have *restricted* SET. **CLEAR (0):** Key usage is not restricted to use on special formats.
17	decrypt	**SET (1):** The private portion of the key may be used to decrypt. **CLEAR (0):** The private portion of the key may not be used to decrypt.
18	sign / encrypt	**SET (1):** For a symmetric cipher object, the private portion of the key may be used to encrypt. For other objects, the private portion of the key may be used to sign. **CLEAR (0):** The private portion of the key may not be used to sign or encrypt.
19	x509sign	**SET (1):** An asymmetric key that may not be used to sign with TPM2_Sign() **CLEAR (0):** A key that may be used with TPM2_Sign() if *sign* is SET NOTE: This attribute only has significance if *sign* is SET.
31:20	Reserved	shall be zero

8.3.3 Attribute Descriptions

8.3.3.1 Introduction

The following remaining paragraphs in 8.3.3 describe the use and settings for each of the TPMA_OBJECT attributes. The description includes checks that are performed on the *objectAttributes* when an object is created, when it is loaded, and when it is imported. In these descriptions:

Creation indicates settings for the *template* parameter in TPM2_Create() or TPM2_CreatePrimary()

Load indicates settings for the *inPublic* parameter in TPM2_Load()

Import indicates settings for the *objectPublic* parameter in TPM2_Import()

External indicates settings that apply to the *inPublic* parameter in TPM2_LoadExternal() if both the public and sensitive portions of the object are loaded

NOTE For TPM2_LoadExternal() when only the public portion of the object is loaded, the only attribute checks are the checks in the validation code following Table 31 and the reserved attributes check.

For any consistency error of attributes in TPMA_OBJECT, the TPM shall return TPM_RC_ATTRIBUTES.

 Copyright © TCG 2006-2020

8.3.3.2 Bit[1] – *fixedTPM*

When SET, the object cannot be duplicated for use on a different TPM, either directly or indirectly and the Qualified Name of the object cannot change. When CLEAR, the object's Qualified Name may change if the object or an ancestor is duplicated.

NOTE This attribute is the logical inverse of the migratable attribute in 1.2. That is, when this attribute is CLEAR, it is the equivalent to a 1.2 object with migratable SET.

Creation If *fixedTPM* is SET in the object's parent, then *fixedTPM* and *fixedParent* shall both be set to the same value in *template.* If *fixedTPM* is CLEAR in the parent, this attribute shall also be CLEAR in *template*.

NOTE For a Primary Object, the parent is considered to have *fixedTPM* SET.

Load If *fixedTPM* is SET in the object's parent, then *fixedTPM* and *fixedParent* shall both be set to the same value. If *fixedTPM* is CLEAR in the parent, this attribute shall also be CLEAR.

Import shall be CLEAR

External shall be CLEAR if both the public and sensitive portions are loaded or if fixedParent is CLEAR, otherwise may be SET or CLEAR

8.3.3.3 Bit[2] – *stClear*

If this attribute is SET, then saved contexts of this object will be invalidated on TPM2_Startup(TPM_SU_CLEAR). If the attribute is CLEAR, then the TPM shall not invalidate the saved context if the TPM received TPM2_Shutdown(TPM_SU_STATE). If the saved state is valid when checked at the next TPM2_Startup(), then the TPM shall continue to be able to use the saved contexts.

Creation may be SET or CLEAR in template

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

8.3.3.4 Bit[4] – *fixedParent*

If this attribute is SET, the object's parent may not be changed. That is, this object may not be the object of a TPM2_Duplicate(). If this attribute is CLEAR, then this object may be the object of a TPM2_Duplicate().

Creation may be SET or CLEAR in template

Load may be SET or CLEAR

Import shall be CLEAR

External shall be CLEAR if both the public and sensitive portions are loaded; otherwise it may be SET or CLEAR

8.3.3.5 Bit[5] – *sensitiveDataOrigin*

This attribute is SET for any key that was generated by TPM in TPM2_Create() or TPM2_CreatePrimary(). If CLEAR, it indicates that the sensitive part of the object (other than the *obfuscation* value) was provided by the caller.

 Copyright © TCG 2006-2020

NOTE 1 If the *fixedTPM* attribute is SET, then this attribute is authoritative and accurately reflects the source of the sensitive area data. If the *fixedTPM* attribute is CLEAR, then validation of this attribute requires evaluation of the properties of the ancestor keys.

Creation If *inSensitive.sensitive.data*.size is zero, then this attribute shall be SET in the template; otherwise, it shall be CLEAR in the template.

NOTE 2 The *inSensitive.sensitive.data.size* parameter is required to be zero for an asymmetric key so *sensitiveDataOrigin* is required to be SET.

NOTE 3 The *inSensitive.sensitive.data.size* parameter may not be zero for a data object so *sensitiveDataOrigin* is required to be CLEAR. A data object has *type* = TPM_ALG_KEYEDHASH and its *sign* and *decrypt* attributes are CLEAR.

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

8.3.3.6 Bit[6] – *userWithAuth*

If SET, authorization for operations that require USER role authorization may be given if the caller provides proof of knowledge of the *authValue* of the object with an HMAC authorization session or a password.

If this attribute is CLEAR, then HMAC or password authorizations may not be used for USER role authorizations.

NOTE 1 Regardless of the setting of this attribute, authorizations for operations that require USER role authorizations may be provided with a policy session that satisfies the object's *authPolicy*.

NOTE 2 Regardless of the setting of this attribute, the *authValue* may be referenced in a policy session or used to provide the *bind* value in TPM2_StartAuthSession(). However, if *userWithAuth* is CLEAR, then the object may be used as the bind object in TPM2_StartAuthSession() but the session cannot be used to authorize actions on the object. If this were allowed, then the *userWithAuth* control could be circumvented simply by using the object as the bind object.

Creation may be SET or CLEAR in template

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

8.3.3.7 Bit[7] – *adminWithPolicy*

If CLEAR, authorization for operations that require ADMIN role may be given if the caller provides proof of knowledge of the *authValue* of the object with an HMAC authorization session or a password.

If this attribute is SET, then then HMAC or password authorizations may not be used for ADMIN role authorizations.

NOTE 1 Regardless of the setting of this attribute, operations that require ADMIN role authorization may be provided by a policy session that satisfies the object's *authPolicy*.

NOTE 2 This attribute is similar to *userWithAuth* but the logic is a bit different. When *userWithAuth* is CLEAR, the *authValue* may not be used for USER mode authorizations. When *adminWithPolicy* is CLEAR, it means that the *authValue* may be used for ADMIN role. Policy may always be used regardless of the setting of *userWithAuth* or *adminWithPolicy*.

 Copyright © TCG 2006-2020

Actions that always require policy (TPM2_Duplicate()) are not affected by the setting of this attribute.

Creation may be SET or CLEAR in *template*

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

8.3.3.8 Bit[10] – *noDA*

If SET, then authorization failures for the object do not affect the dictionary attack protection logic and authorization of the object is not blocked if the TPM is in lockout.

Creation may be SET or CLEAR in *template*

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

8.3.3.9 Bit[11] – *encryptedDuplication*

If SET, then when the object is duplicated, the sensitive portion of the object is required to be encrypted with an inner wrapper and the new parent shall be an asymmetric key and not TPM_RH_NULL

NOTE 1 Enforcement of these requirements in TPM2_Duplicate() is by not allowing *symmetricAlg* to be TPM_ALG_NULL and not allowing *newParentHandle* to be TPM_RH_NULL.

This attribute shall not be SET in any object that has *fixedTPM* SET**.**

NOTE 2 This requirement means that *encryptedDuplication* may not be SET if the object cannot be directly or indirectly duplicated.

If an object's parent has *fixedTPM* SET, and the object is duplicable (*fixedParent* == CLEAR), then *encryptedDuplication* may be SET or CLEAR in the object.

NOTE 3 This allows the object at the boundary between duplicable and non-duplicable objects to have either setting.

If an object's parent has *fixedTPM* CLEAR, then the object is required to have the same setting of *encryptedDuplication* as its parent.

NOTE 4 This requirement forces all duplicable objects in a duplication group to have the same *encryptedDuplication* setting.

Creation shall be CLEAR if *fixedTPM* is SET. If *fixedTPM* is CLEAR, then this attribute shall have the same value as its parent unless *fixedTPM* is SET in the object's parent, in which case, it may be SET or CLEAR.

Load shall be CLEAR if *fixedTPM* is SET. If *fixedTPM* is CLEAR, then this attribute shall have the same value as its parent, unless *fixedTPM* is SET the parent, in which case, it may be SET or CLEAR.

Import if *fixedTPM* is SET in the object's new parent, then this attribute may be SET or CLEAR, otherwise, it shall have the same setting as the new parent.

External may be SET or CLEAR.

 Copyright © TCG 2006-2020

8.3.3.10 Bit[16] – *restricted*

This this attribute modifies the *decrypt* and *sign* attributes of an object.

NOTE A key with this object CLEAR may not be a parent for another object.

Creation shall be CLEAR in *template* if neither sign nor decrypt is SET in *template*.

Load shall be CLEAR if neither sign nor decrypt is SET in the object

Import may be SET or CLEAR

External shall be CLEAR

8.3.3.11 Bit[17] – *decrypt*

When SET, the private portion of this key can be used to decrypt an external blob. If *restricted* is SET, then the TPM will return an error if the external decrypted blob is not formatted as appropriate for the command.

NOTE 1 Since TPM-generated keys and sealed data will contain a hash and a structure tag, the TPM can ensure that it is not being used to improperly decrypt and return sensitive data that should not be returned. The only type of data that may be returned after decryption is a Sealed Data Object (a *keyedHash* object with *decrypt* and *sign* CLEAR).

When *restricted* is CLEAR, there are no restrictions on the use of the private portion of the key for decryption and the key may be used to decrypt and return any structure encrypted by the public portion of the key.

NOTE 2 A key with this attribute SET may be a parent for another object if *restricted* is SET and *sign* is CLEAR.

If *decrypt* is SET on an object with *type* set to TPM_ALG_KEYEDHASH, it indicates that the object is an XOR encryption key.

Creation may be SET or CLEAR in *template*

Load may be SET or CLEAR

Import may be SET or CLEAR

External may be SET or CLEAR

 Copyright © TCG 2006-2020

8.3.3.12 Bit[18] – *sign / encrypt*

When SET, the private portion of this key may be used to sign a digest if the key is an asymetric key or to encrypt a block of data if the key is a symmetric key. If *restricted* is SET, then the asymmetric key may only be used to sign a digest that was computed by the TPM. A restricted symmetric key may only be used to encrypt a data block. If a structure is generated by the TPM, it will begin with TPM_GENERATED_VALUE and the TPM may sign the digest of that structure. If the data is externally supplied and has TPM_GENERATED_VALUE as its first octets, then the TPM will not sign a digest of that data with a restricted signing key.

If *restricted* is CLEAR, then the key may be used to sign any digest or encrypt any data block, whether generated by the TPM or externally provided.

NOTE 1 Some asymmetric algorithms may not support both *sign* and *decrypt* being SET in the same key.

If *sign* is SET on an object with *type* set to TPM_ALG_KEYEDHASH, it indicates that the object is an HMAC key.

NOTE 2 A key with this attribute SET may not be a parent for another object.

Creation shall not be SET if *decrypt* and *restricted* are both SET

Load shall not be SET if *decrypt* and *restricted* are both SET

Import shall not be SET if *decrypt* and *restricted* are both SET

External shall not be SET if *decrypt* and *restricted* are both SET

8.3.3.13 Bit[19] – *x509sign*

When SET, the private portion of the asymmetric key may not be used as the signing key in TPM2_Sign(). This restriction is to ensure that the only digest signed by this key is a digest of a strucure that is specific to the TPM or an x509 certiticate.

NOTE 1 This attribute does not limit the use of the key in any command other than TPM2_Sign().

NOTE 2 This attribute was added in revision 01.53.

This attribute may not be SET if the object is not an asymmetric key or if *sign* is CLEAR.

Creation shall not be SET if *sign* is CLEAR or if the object is not an asymmetric key

Load shall not be SET if *sign* is CLEAR or if the object is not an asymmetric key

Import shall not be SET if *sign* is CLEAR or if the object is not an asymmetric key

External shall not be SET if *sign* is CLEAR or if the object is not an asymmetric key

 Copyright © TCG 2006-2020

8.4 TPMA_SESSION (Session Attributes)

This octet in each session is used to identify the session type, indicate its relationship to any handles in the command, and indicate its use in parameter encryption.

If a session is not being used for authorization, at least one of decrypt, encrypt, or audit must be SET.

In this revision, if *audit* is CLEAR, *auditExclusive* must be CLEAR in the command and will be CLEAR in the response. In a future, revision, this bit may have a different meaning if *audit* is CLEAR. See "Exclusive Audit Session" clause in TPM 2.0 Part 1.

In this revision, if *audit* is CLEAR, *auditReset* must be clear in the command and will be CLEAR in the response. In a future, revision, this bit may have a different meaning if *audit* is CLEAR.

decrypt may only be SET in one session per command. It may only be SET if the first parameter of the command is a sized buffer (TPM2B_).

encrypt may only be SET in one session per command. It may only be SET if the first parameter of the response is a sized buffer (TPM2B_).

audit may only be SET in one session per command or response.

Table 32 — Definition of (UINT8) TPMA_SESSION Bits <IN/OUT>

Bit	Name	Meaning
0	continueSession	**SET (1):** In a command, this setting indicates that the session is to remain active after successful completion of the command. In a response, it indicates that the session is still active. If SET in the command, this attribute shall be SET in the response. **CLEAR (0):** In a command, this setting indicates that the TPM should close the session and flush any related context when the command completes successfully. In a response, it indicates that the session is closed and the context is no longer active. This attribute has no meaning for a password authorization and the TPM will allow any setting of the attribute in the command and SET the attribute in the response. This attribute will only be CLEAR in one response for a logical session. If the attribute is CLEAR, the context associated with the session is no longer in use and the space is available. A session created after another session is ended may have the same handle but logically is not the same session. This attribute has no effect if the command does not complete successfully.
1	auditExclusive	**SET (1):** In a command, this setting indicates that the command should only be executed if the session is exclusive at the start of the command. In a response, it indicates that the session is exclusive. This setting is only allowed if the *audit* attribute is SET (TPM_RC_ATTRIBUTES). **CLEAR (0):** In a command, indicates that the session need not be exclusive at the start of the command. In a response, indicates that the session is not exclusive.
2	auditReset	**SET (1):** In a command, this setting indicates that the audit digest of the session should be initialized and the exclusive status of the session SET. This setting is only allowed if the *audit* attribute is SET (TPM_RC_ATTRIBUTES). **CLEAR (0):** In a command, indicates that the audit digest should not be initialized. This bit is always CLEAR in a response.
4:3	Reserved	shall be CLEAR

 Copyright © TCG 2006-2020

Bit	Name	Meaning
5	decrypt	**SET (1):** In a command, this setting indicates that the first parameter in the command is symmetrically encrypted using the parameter encryption scheme described in TPM 2.0 Part 1. The TPM will decrypt the parameter after performing any HMAC computations and before unmarshaling the parameter. In a response, the attribute is copied from the request but has no effect on the response. **CLEAR (0):** Session not used for encryption. For a password authorization, this attribute will be CLEAR in both the command and response. This attribute may be SET in a session that is not associated with a command handle. Such a session is provided for purposes of encrypting a parameter and not for authorization. This attribute may be SET in combination with any other session attributes.
6	encrypt	**SET (1):** In a command, this setting indicates that the TPM should use this session to encrypt the first parameter in the response. In a response, it indicates that the attribute was set in the command and that the TPM used the session to encrypt the first parameter in the response using the parameter encryption scheme described in TPM 2.0 Part 1. **CLEAR (0):** Session not used for encryption. For a password authorization, this attribute will be CLEAR in both the command and response. This attribute may be SET in a session that is not associated with a command handle. Such a session is provided for purposes of encrypting a parameter and not for authorization.
7	audit	**SET (1):** In a command or response, this setting indicates that the session is for audit and that *auditExclusive* and *auditReset* have meaning. This session may also be used for authorization, encryption, or decryption. The *encrypted* and *encrypt* fields may be SET or CLEAR. **CLEAR (0):** Session is not used for audit. If SET in the command, then this attribute will be SET in the response.

 Copyright © TCG 2006-2020

8.5 TPMA_LOCALITY (Locality Attribute)

In a TPMS_CREATION_DATA structure, this structure is used to indicate the locality of the command that created the object. No more than one of the locality attributes shall be set in the creation data.

When used in TPM2_PolicyLocality(), this structure indicates which localities are approved by the policy. When a policy is started, all localities are allowed. If TPM2_PolicyLocality() is executed, it indicates that the command may only be executed at specific localities. More than one locality may be selected.

EXAMPLE 1 TPM_LOC_TWO would indicate that only locality 2 is authorized.

EXAMPLE 2 TPM_LOC_ONE + TPM_LOC_TWO would indicate that locality 1 or 2 is authorized.

EXAMPLE 3 TPM_LOC_FOUR + TPM_LOC_THREE would indicate that localities 3 or 4 are authorized.

EXAMPLE 4 A value of 21_{16} would represent a locality of 33.

NOTE Locality values of 5 through 31 are not selectable.

If Extended is non-zero, then an extended locality is indicated and the TPMA_LOCALITY contains an integer value.

Table 33 — Definition of (UINT8) TPMA_LOCALITY Bits <IN/OUT>

Bit	Name	Definition
0	TPM_LOC_ZERO	
1	TPM_LOC_ONE	
2	TPM_LOC_TWO	
3	TPM_LOC_THREE	
4	TPM_LOC_FOUR	
7:5	Extended	If any of these bits is set, an extended locality is indicated

 Copyright © TCG 2006-2020

8.6 TPMA_PERMANENT

The attributes in this structure are persistent and are not changed as a result of _TPM_Init or any TPM2_Startup(). Some of the attributes in this structure may change as the result of specific Protected Capabilities. This structure may be read using TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTIES, *property* = TPM_PT_PERMANENT).

Table 34 — Definition of (UINT32) TPMA_PERMANENT Bits <OUT>

Bit	Parameter	Description
0	ownerAuthSet	**SET (1):** TPM2_HierarchyChangeAuth() with *ownerAuth* has been executed since the last TPM2_Clear(). **CLEAR (0):** o*wnerAuth* has not been changed since TPM2_Clear().
1	endorsementAuthSet	**SET (1):** TPM2_HierarchyChangeAuth() with *endorsementAuth* has been executed since the last TPM2_Clear(). **CLEAR (0):** endorsementAuth has not been changed since TPM2_Clear().
2	lockoutAuthSet	**SET (1):** TPM2_HierarchyChangeAuth() with *lockoutAuth* has been executed since the last TPM2_Clear(). **CLEAR (0):** *lockoutAuth* has not been changed since TPM2_Clear().
7:3	Reserved	
8	disableClear	**SET (1):** TPM2_Clear() is disabled. **CLEAR (0):** TPM2_Clear() is enabled. NOTE See “TPM2_ClearControl” in TPM 2.0 Part 3 for details on changing this attribute.
9	inLockout	**SET (1):** The TPM is in lockout, when *failedTries* is equal to *maxTries*.
10	tpmGeneratedEPS	**SET (1):** The EPS was created by the TPM. **CLEAR (0):** The EPS was created outside of the TPM using a manufacturer-specific process.
31:11	Reserved	

 Copyright © TCG 2006-2020

8.7 TPMA_STARTUP_CLEAR

This structure may be read using TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTIES, *property* = TPM_PT_STARTUP_CLEAR).

phEnable is SET on any TPM2_Startup. *shEnable*, *ehEnable*, and *phEnableNV* are SET on TPM Reset or TPM_Restart and preserved by TPM Resume.

Some of attributes may be changed as the result of specific Protected Capabilities.

Table 35 — Definition of (UINT32) TPMA_STARTUP_CLEAR Bits <OUT>

Bit	Parameter	Description
0	phEnable	**SET (1):** The platform hierarchy is enabled and *platformAuth* or *platformPolicy* may be used for authorization. **CLEAR (0):** *platformAuth* and *platformPolicy* may not be used for authorizations, and objects in the platform hierarchy, including persistent objects, cannot be used. NOTE See "TPM2_HierarchyControl" in TPM 2.0 Part 3 for details on changing this attribute.
1	shEnable	**SET (1):** The Storage hierarchy is enabled and *ownerAuth* or *ownerPolicy* may be used for authorization. NV indices defined using owner authorization are accessible. **CLEAR (0):** *ownerAuth* and *ownerPolicy* may not be used for authorizations, and objects in the Storage hierarchy, persistent objects, and NV indices defined using owner authorization cannot be used. NOTE See "TPM2_HierarchyControl" in TPM 2.0 Part 3 for details on changing this attribute.
2	ehEnable	**SET (1):** The EPS hierarchy is enabled and Endorsement Authorization may be used to authorize commands. **CLEAR (0):** Endorsement Authorization may not be used for authorizations, and objects in the endorsement hierarchy, including persistent objects, cannot be used. NOTE See "TPM2_HierarchyControl" in TPM 2.0 Part 3 for details on changing this attribute.
3	phEnableNV	**SET (1):** NV indices that have TPMA_NV_PLATFORMCREATE SET may be read or written. The platform can create define and undefine indices. **CLEAR (0):** NV indices that have TPMA_NV_PLATFORMCREATE SET may not be read or written (TPM_RC_HANDLE). The platform cannot define (TPM_RC_HIERARCHY) or undefined (TPM_RC_HANDLE) indices. NOTE See "TPM2_HierarchyControl" in TPM 2.0 Part 3 for details on changing this attribute. NOTE read refers to these commands: TPM2_NV_Read, TPM2_NV_ReadPublic, TPM_NV_Certify, TPM2_PolicyNV write refers to these commands: TPM2_NV_Write, TPM2_NV_Increment, TPM2_NV_Extend, TPM2_NV_SetBits NOTE The TPM must query the index TPMA_NV_PLATFORMCREATE attribute to determine whether phEnableNV is applicable. Since the TPM will return TPM_RC_HANDLE if the index does not exist, it also returns this error code if the index is disabled. Otherwise, the TPM would leak the existence of an index even when disabled.
30:4	Reserved	shall be zero

 Copyright © TCG 2006-2020

Bit	Parameter	Description
31	orderly	**SET (1):** The TPM received a TPM2_Shutdown() and a matching TPM2_Startup(). **CLEAR (0):** TPM2_Startup(TPM_SU_CLEAR) was not preceded by a TPM2_Shutdown() of any type. NOTE A shutdown is orderly if the TPM receives a TPM2_Shutdown() of any type followed by a TPM2_Startup() of any type. However, the TPM will return an error if TPM2_Startup(TPM_SU_STATE) was not preceded by TPM2_Shutdown(TPM_SU_STATE).

8.8 TPMA_MEMORY

This structure of this attribute is used to report the memory management method used by the TPM for transient objects and authorization sessions. This structure may be read using TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTIES, *property* = TPM_PT_MEMORY).

If the RAM memory is shared, then context save of a session may make it possible to load an additional transient object.

Table 36 — Definition of (UINT32) TPMA_MEMORY Bits <Out>

Bit	Name	Definition
0	sharedRAM	**SET (1):** indicates that the RAM memory used for authorization session contexts is shared with the memory used for transient objects **CLEAR (0):** indicates that the memory used for authorization sessions is not shared with memory used for transient objects
1	sharedNV	**SET (1):** indicates that the NV memory used for persistent objects is shared with the NV memory used for NV Index values **CLEAR (0):** indicates that the persistent objects and NV Index values are allocated from separate sections of NV
2	objectCopiedToRam	**SET (1):** indicates that the TPM copies persistent objects to a transient-object slot in RAM when the persistent object is referenced in a command. The TRM is required to make sure that an object slot is available. **CLEAR (0):** indicates that the TPM does not use transient-object slots when persistent objects are referenced
31:3	Reserved	shall be zero

 Copyright © TCG 2006-2020

8.9 TPMA_CC (Command Code Attributes)

8.9.1 Introduction

This structure defines the attributes of a command from a context management perspective. The fields of the structure indicate to the TPM Resource Manager (TRM) the number of resources required by a command and how the command affects the TPM's resources.

This structure is only used in a list returned by the TPM in response to TPM2_GetCapability(capability = TPM_CAP_COMMANDS).

For a command to the TPM, only the *commandIndex* field and *V* attribute are allowed to be non-zero.

8.9.2 Structure Definition

Table 37 — Definition of (TPM_CC) TPMA_CC Bits <OUT>

Bit	Name	Definition
15:0	commandIndex	indicates the command being selected
21:16	Reserved	shall be zero
22	nv	**SET (1):** indicates that the command may write to NV **CLEAR (0):** indicates that the command does not write to NV
23	extensive	**SET (1):** This command could flush any number of loaded contexts. **CLEAR (0):** no additional changes other than indicated by the *flushed* attribute
24	flushed	**SET (1):** The context associated with any transient handle in the command will be flushed when this command completes. **CLEAR (0):** No context is flushed as a side effect of this command.
27:25	cHandles	indicates the number of the handles in the handle area for this command
28	rHandle	**SET (1):** indicates the presence of the handle area in the response
29	V	**SET (1):** indicates that the command is vendor-specific **CLEAR (0):** indicates that the command is defined in a version of this specification
31:30	Res	allocated for software; shall be zero

8.9.3 Field Descriptions

8.9.3.1 Bits[15:0] – *commandIndex*

This is the command index of the command in the set of commands. The two sets are defined by the *V* attribute. If *V* is zero, then the *commandIndex* shall be in the set of commands defined in a version of this specification. If *V* is one, then the meaning of *commandIndex* is as determined by the TPM vendor.

8.9.3.2 Bit[22] – *nv*

If this attribute is SET, then the TPM may perform an NV write as part of the command actions. This write is independent of any write that may occur as a result of dictionary attack protection. If this attribute is CLEAR, then the TPM shall not perform an NV write as part of the command actions.

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

8.9.3.3 Bit[23] – *extensive*

If this attribute is SET, then the TPM may flush many transient objects as a side effect of this command. In TPM 2.0 Part 3, a command that has this attribute is indicated by using a "{E}" decoration in the "Description" column of the *commandCode* parameter.

EXAMPLE See "TPM2_Clear" in TPM 2.0 Part 3.

NOTE The "{E}" decoration may be combined with other decorations such as "{NV}" in which case the decoration would be "{NV E}."

8.9.3.4 Bit[24] – *flushed*

If this attribute is SET, then the TPM will flush transient objects as a side effect of this command. Any transient objects listed in the handle area of the command will be flushed from TPM memory. Handles associated with persistent objects, sessions, PCR, or other fixed TPM resources are not flushed.

NOTE The TRM is expected to use this value to determine how many objects are loaded into transient TPM memory.

NOTE The "{F}" decoration may be combined with other decorations such as "{NV}" in which case the decoration would be "{NV F}."

If this attribute is SET for a command, and the handle of the command is associated with a hierarchy (TPM_RH_PLATFORM, TPM_RH_OWNER, or TPM_RH_ENDORSEMENT), all loaded objects in the indicated hierarchy are flushed.

The TRM is expected to know the behaviour of TPM2_ContextSave(), and sessions are flushed when context saved, but objects are not. The *flushed* attribute for that command shall be CLEAR.

In TPM 2.0 Part 3, a command that has this attribute is indicated by using a "{F}" decoration in the "Description" column of the *commandCode* parameter.

EXAMPLE See "TPM2_SequenceComplete" in TPM 2.0 Part 3."

8.9.3.5 Bits[27:25] – *cHandles*

This field indicates the number of handles in the handle area of the command. This number allows the TRM to enumerate the handles in the handle area and find the position of the authorizations (if any).

8.9.3.6 Bit[28] – *rHandle*

If this attribute is SET, then the response to this command has a handle area. This area will contain no more than one handle. This field is necessary to allow the TRM to locate the *parameterSize* field in the response, which is then used to locate the authorizations.

NOTE The TRM is expected to "virtualize" the handle value for any returned handle.

A TPM command is only allowed to have one handle in the response handle area.

8.9.3.7 Bit[29] – V

When this attribute is SET, it indicates that the command operation is defined by the TPM vendor. When CLEAR, it indicates that the command is defined by a version of this specification.

 Copyright © TCG 2006-2020

8.9.3.8 Bits[31:30] – Res

This field is reserved for system software. This field is required to be zero for a command to the TPM.

8.10 TPMA_MODES

This structure of this attribute is used to report that the TPM is designed for these modes. This structure may be read using TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTIES, *property* = TPM_PT_MODES).

NOTE: To determine the certification status of a TPM with the FIPS_140_2 attribute SET, consult the NIST Module Validation List at http://csrc.nist.gov/groups/STM/cmvp/validation.html.

Table 38 — Definition of (UINT32) TPMA_MODES Bits <Out>

Bit	Name	Definition
0	FIPS_140_2	**SET (1):** indicates that the TPM is designed to comply with all of the FIPS 140-2 requirements at Level 1 or higher.
31:1	Reserved	shall be zero

 Copyright © TCG 2006-2020

8.11 TPMA_X509_KEY_USAGE

These attributes are as specified in clause 4.2.1.3. of RFC 5280 *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile.* For TPM2_CertifyX509, when a caller provides a DER encoded Key Usage in *partialCertificate*, the TPM will validate that the key to be certified meets the requirements of Key Usage.

RFC 5280 describes these attributes in terms of how the public key in the certificate should be used. The TPM needs to check that the attributes of the key allow the private part of the key to be used for a purpose that is complimentary to the use of the public key. That is, if the public key should be used to verify signatures, the private key needs to be able to create the signatures (have *sign* SET).

This structure is defined to provide labels of the attributes for use by the TPM code that validates the attributes. This structure is input to the TPM as a DER encoded structure and not in the normal, TPM-canonical form.

This structure is only input to the TPM in a DER-encoded structure and is not present on the interface in canonical TPM format.

Table 39 — Definition of (UINT32) TPMA_X509_KEY_USAGE Bits<>

Bit	Atrribute	Requirements
22:0	Reserved	
23	decipherOnly	Attributes.Decrypt SET
24	encipherOnly	Attributes.Decrypt SET
25	cRLSign	Attributes.sign SET
26	keyCertSign	Attributes.sign SET
27	keyAgreement	Attributes.Decrypt SET
28	dataEncipherment	Attributes.Decrypt SET
29	keyEncipherment	asymmetric key with *decrypt* and *restricted* SET – key has the attributes of a parent key
30	nonrepudiation/contentCommitment	*fixedTPM* SET in Subject Key (*objectHandle*)
31	digitalSignature	*sign* SET in Subject Key (*objectHandle*)

 Copyright © TCG 2006-2020

8.12 TPMA_ACT

This attribute is used to report the ACT state. This attribute may be read using TPM2_GetCapability(*capability* = TPM_CAP_ACT, *property* = TPM_RH_ACT_”x” where “x” is the ACT number (0-F)). The *signaled* value must be preserved across TPM Resume or if the TPM has not lost power. The *signaled* value may be preserved over a power cycle of a TPM.

NOTE: The ACT signaled value is reset to zero when the ACT is next accessed by TPM2_ACT_SetTimeout() with a non-zero *startTimeout*.

Table 39 — Definition of (UINT32) TPMA_ACT Bits

Bit	Name	Definition
0	signaled	**SET (1):** The ACT has signaled **CLEAR (0):** The ACT has not signaled
1	preserveSignaled	**SET (1):** The ACT signaled bit is preserved over a power cycle **CLEAR (0):** The ACT signaled bit is not preserved over a power cycle
31:2	Reserved	shall be zero

9 Interface Types

9.1 Introduction

Clause 8.11 contains definitions for interface types. An interface type is type checked when it is unmarshaled. These types are based on an underlying type that is indicated in the table title by the value in parentheses. When an interface type is used, the base type is unmarshaled and then checked to see if it has one of the allowed values.

9.2 TPMI_YES_NO

This interface type is used in place of a Boolean type in order to eliminate ambiguity in the handling of a octet that conveys a single bit of information. This type only has two allowed values, YES (1) and NO (0).

NOTE This list is not used as input to the TPM.

Table 40 — Definition of (BYTE) TPMI_YES_NO Type

Value	Description
NO	a value of 0
YES	a value of 1
#TPM_RC_VALUE	

9.3 TPMI_DH_OBJECT

The TPMI_DH_OBJECT interface type is a handle that references a loaded object. The handles in this set are used to refer to either transient or persistent object. The range of these values would change according to the TPM implementation.

NOTE These interface types should not be used by system software to qualify the keys produced by the TPM. The value returned by the TPM shall be used to reference the object.

Table 41 — Definition of (TPM_HANDLE) TPMI_DH_OBJECT Type

Values	Comments
{TRANSIENT_FIRST:TRANSIENT_LAST}	allowed range for transient objects
{PERSISTENT_FIRST:PERSISTENT_LAST}	allowed range for persistent objects
+TPM_RH_NULL	the conditional value
#TPM_RC_VALUE	

 Copyright © TCG 2006-2020

9.4 TPMI_DH_PARENT

The TPMI_DH_PARENT interface type is a handle that references an object that can be the parent of another object. The handles in this set may refer to either transient or persistent object or to Primary Seeds.

Table 42 — Definition of (TPM_HANDLE) TPMI_DH_PARENT Type

Values	Comments
{TRANSIENT_FIRST:TRANSIENT_LAST}	allowed range for transient objects
{PERSISTENT_FIRST:PERSISTENT_LAST}	allowed range for persistent objects
TPM_RH_OWNER	Storage hierarchy
TPM_RH_PLATFORM	Platform hierarchy
TPM_RH_ENDORSEMENT	Endorsement hierarchy
+TPM_RH_NULL	no hierarchy
#TPM_RC_VALUE	

9.5 TPMI_DH_PERSISTENT

The TPMI_DH_PERSISTENT interface type is a handle that references a location for a transient object. This type is used in TPM2_EvictControl() to indicate the handle to be assigned to the persistent object.

Table 43 — Definition of (TPM_HANDLE) TPMI_DH_PERSISTENT Type

Values	Comments
{PERSISTENT_FIRST:PERSISTENT_LAST}	allowed range for persistent objects
#TPM_RC_VALUE	

 Copyright © TCG 2006-2020

9.6 TPMI_DH_ENTITY

The TPMI_DH_ENTITY interface type is TPM-defined values that are used to indicate that the handle refers to an *authValue*. The range of these values would change according to the TPM implementation.

Table 44 — Definition of (TPM_HANDLE) TPMI_DH_ENTITY Type <IN>

Values	Comments
TPM_RH_OWNER	
TPM_RH_ENDORSEMENT	
TPM_RH_PLATFORM	
TPM_RH_LOCKOUT	
{TRANSIENT_FIRST : TRANSIENT_LAST}	range of object handles
{PERSISTENT_FIRST : PERSISTENT_LAST}	
{NV_INDEX_FIRST : NV_INDEX_LAST}	
{PCR_FIRST : PCR_LAST}	
{TPM_RH_AUTH_00 : TPM_RH_AUTH_FF}	range of vendor-specific authorization values
+TPM_RH_NULL	conditional value
#TPM_RC_VALUE	

9.7 TPMI_DH_PCR

This interface type consists of the handles that may be used as PCR references. The upper end of this range of values would change according to the TPM implementation.

NOTE 1 Typically, the 0th PCR will have a handle value of zero.

NOTE 2 The handle range for PCR is defined to be the same as the handle range for PCR in previous versions of TPM specifications.

Table 45 — Definition of (TPM_HANDLE) TPMI_DH_PCR Type <IN>

Values	Comments
{PCR_FIRST:PCR_LAST}	
+TPM_RH_NULL	conditional value
#TPM_RC_VALUE	

 Copyright © TCG 2006-2020

9.8 TPMI_SH_AUTH_SESSION

The TPMI_SH_AUTH_SESSION interface type is TPM-defined values that are used to indicate that the handle refers to an authorization session.

Table 46 — Definition of (TPM_HANDLE) TPMI_SH_AUTH_SESSION Type <IN/OUT>

Values	Comments
{HMAC_SESSION_FIRST : HMAC_SESSION_LAST}	range of HMAC authorization session handles
{POLICY_SESSION_FIRST: POLICY_SESSION_LAST}	range of policy authorization session handles
+TPM_RS_PW	a password authorization
#TPM_RC_VALUE	error returned if the handle is out of range

9.9 TPMI_SH_HMAC

This interface type is used for an authorization handle when the authorization session uses an HMAC.

Table 47 — Definition of (TPM_HANDLE) TPMI_SH_HMAC Type <IN/OUT>

Values	Comments
{HMAC_SESSION_FIRST: HMAC_SESSION_LAST}	range of HMAC authorization session handles
#TPM_RC_VALUE	error returned if the handle is out of range

9.10 TPMI_SH_POLICY

This interface type is used for a policy handle when it appears in a policy command.

Table 48 — Definition of (TPM_HANDLE) TPMI_SH_POLICY Type <IN/OUT>

Values	Comments
{POLICY_SESSION_FIRST: POLICY_SESSION_LAST}	range of policy authorization session handles
#TPM_RC_VALUE	error returned if the handle is out of range

9.11 TPMI_DH_CONTEXT

This type defines the handle values that may be used in TPM2_ContextSave() or TPM2_Flush().

Table 49 — Definition of (TPM_HANDLE) TPMI_DH_CONTEXT Type

Values	Comments
{HMAC_SESSION_FIRST : HMAC_SESSION_LAST}	
{POLICY_SESSION_FIRST:POLICY_SESSION_LAST}	
{TRANSIENT_FIRST:TRANSIENT_LAST}	
#TPM_RC_VALUE	

 Copyright © TCG 2006-2020

9.12 TPMI_DH_SAVED

This type defines the handle values that may be used in TPM2_ContextSave() or TPM2_FlushContext().

Table 50 — Definition of (TPM_HANDLE) TPMI_DH_SAVED Type

Values	Comments
{HMAC_SESSION_FIRST : HMAC_SESSION_LAST}	an HMAC session context
{POLICY_SESSION_FIRST:POLICY_SESSION_LAST}	a policy session context
0x80000000	an ordinary transient object
0x80000001	a sequence object
0x80000002	a transient object with the *stClear* attribute SET
#TPM_RC_VALUE	

9.13 TPMI_RH_HIERARCHY

The TPMI_RH_HIERARCHY interface type is used as the type of a handle in a command when the handle is required to be one of the hierarchy selectors.

Table 51 — Definition of (TPM_HANDLE) TPMI_RH_HIERARCHY Type

Values	Comments
TPM_RH_OWNER	Storage hierarchy
TPM_RH_PLATFORM	Platform hierarchy
TPM_RH_ENDORSEMENT	Endorsement hierarchy
+TPM_RH_NULL	no hierarchy
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.14 TPMI_RH_ENABLES

The TPMI_RH_ENABLES interface type is used as the type of a handle in a command when the handle is required to be one of the hierarchy or NV enables.

Table 52 — Definition of (TPM_HANDLE) TPMI_RH_ENABLES Type

Values	Comments
TPM_RH_OWNER	Storage hierarchy
TPM_RH_PLATFORM	Platform hierarchy
TPM_RH_ENDORSEMENT	Endorsement hierarchy
TPM_RH_PLATFORM_NV	Platform NV
+TPM_RH_NULL	no hierarchy
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

 Copyright © TCG 2006-2020

9.15 TPMI_RH_HIERARCHY_AUTH

This interface type is used as the type of a handle in a command when the handle is required to be one of the hierarchy selectors or the Lockout Authorization.

Table 53 — Definition of (TPM_HANDLE) TPMI_RH_HIERARCHY_AUTH Type <IN>

Values	Comments
TPM_RH_OWNER	Storage hierarchy
TPM_RH_PLATFORM	Platform hierarchy
TPM_RH_ENDORSEMENT	Endorsement hierarchy
TPM_RH_LOCKOUT	Lockout Authorization
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.16 TPMI_RH_HIERARCHY_POLICY

This interface type is used as the type of a handle in a command when the handle is required to be one of the hierarchy selectors, the Lockout Authorization, or an ACT. This type is used in TPM2_SetPrimaryPolicy().

Table 54 — Definition of (TPM_HANDLE) TPMI_RH_HIERARCHY_POLICY Type <IN>

Values	Comments
TPM_RH_OWNER	Storage hierarchy
TPM_RH_PLATFORM	Platform hierarchy
TPM_RH_ENDORSEMENT	Endorsement hierarchy
TPM_RH_LOCKOUT	Lockout Authorization
{TPM_RH_ACT_0:TPM_RH_ACT_F}	Authenticated Countdown Timer
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.17 TPMI_RH_PLATFORM

The TPMI_RH_PLATFORM interface type is used as the type of a handle in a command when the only allowed handle is TPM_RH_PLATFORM indicating that Platform Authorization is required.

Table 55 — Definition of (TPM_HANDLE) TPMI_RH_PLATFORM Type <IN>

Values	Comments
TPM_RH_PLATFORM	Platform hierarchy
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

Copyright © TCG 2006-2020

9.18 TPMI_RH_OWNER

This interface type is used as the type of a handle in a command when the only allowed handle is TPM_RH_OWNER indicating that Owner Authorization is required.

Table 56 — Definition of (TPM_HANDLE) TPMI_RH_OWNER Type <IN>

Values	Comments
TPM_RH_OWNER	Owner hierarchy
+TPM_RH_NULL	may allow the null handle
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.19 TPMI_RH_ENDORSEMENT

This interface type is used as the type of a handle in a command when the only allowed handle is TPM_RH_ENDORSEMENT indicating that Endorsement Authorization is required.

Table 57 — Definition of (TPM_HANDLE) TPMI_RH_ENDORSEMENT Type <IN>

Values	Comments
TPM_RH_ENDORSEMENT	Endorsement hierarchy
+TPM_RH_NULL	may allow the null handle
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.20 TPMI_RH_PROVISION

The TPMI_RH_PROVISION interface type is used as the type of the handle in a command when the only allowed handles are either TPM_RH_OWNER or TPM_RH_PLATFORM indicating that either Platform Authorization or Owner Authorization are allowed.

In most cases, either Platform Authorization or Owner Authorization may be used to authorize the commands used for management of the resources of the TPM and this interface type will be used.

Table 58 — Definition of (TPM_HANDLE) TPMI_RH_PROVISION Type <IN>

Value	Comments
TPM_RH_OWNER	handle for Owner Authorization
TPM_RH_PLATFORM	handle for Platform Authorization
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

 Copyright © TCG 2006-2020

9.21 TPMI_RH_CLEAR

The TPMI_RH_CLEAR interface type is used as the type of the handle in a command when the only allowed handles are either TPM_RH_LOCKOUT or TPM_RH_PLATFORM indicating that either Platform Authorization or Lockout Authorization are allowed.

This interface type is normally used for performing or controlling TPM2_Clear().

Table 59 — Definition of (TPM_HANDLE) TPMI_RH_CLEAR Type <IN>

Value	Comments
TPM_RH_LOCKOUT	handle for Lockout Authorization
TPM_RH_PLATFORM	handle for Platform Authorization
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.22 TPMI_RH_NV_AUTH

This interface type is used to identify the source of the authorization for access to an NV location. The handle value of a TPMI_RH_NV_AUTH shall indicate that the authorization value is either Platform Authorization, Owner Authorization, or the *authValue.* This type is used in the commands that access an NV Index (commands of the form TPM2_NV_xxx) other than TPM2_NV_DefineSpace() and TPM2_NV_UndefineSpace().

Table 60 — Definition of (TPM_HANDLE) TPMI_RH_NV_AUTH Type <IN>

Value	Comments
TPM_RH_PLATFORM	Platform Authorization is allowed
TPM_RH_OWNER	Owner Authorization is allowed
{NV_INDEX_FIRST:NV_INDEX_LAST}	range for NV locations
#TPM_RC_VALUE	response code returned when unmarshaling of this type fails

9.23 TPMI_RH_LOCKOUT

The TPMI_RH_LOCKOUT interface type is used as the type of a handle in a command when the only allowed handle is TPM_RH_LOCKOUT indicating that Lockout Authorization is required.

Table 61 — Definition of (TPM_HANDLE) TPMI_RH_LOCKOUT Type <IN>

Value	Comments
TPM_RH_LOCKOUT	handle for Lockout Authorization
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

 Copyright © TCG 2006-2020

9.24 TPMI_RH_NV_INDEX

This interface type is used to identify an NV location. This type is used in the NV commands.

Table 62 — Definition of (TPM_HANDLE) TPMI_RH_NV_INDEX Type <IN/OUT>

Value	Comments
{NV_INDEX_FIRST:NV_INDEX_LAST}	Range of NV Indexes
#TPM_RC_VALUE	error returned if the handle is out of range

9.25 TPMI_RH_AC

This interface type is used to identify an attached component. This type is used in the AC commands.

Table 63 — Definition of (TPM_HANDLE) TPMI_RH_AC Type <IN>

Value	Comments
{AC_FIRST:AC_LAST}	Range of AC handles
#TPM_RC_VALUE	error returned if the handle is out of range

 Copyright © TCG 2006-2020

9.26 TPMI_RH_ACT

This interface type is used to identify the ACT instance used in TPM2_ACT_SetTimeout().

Table 64 — Definition of (TPM_HANDLE) TPMI_RH_ACT Type

Value	Comments
{TPM_RH_ACT_0:TPM_RH_ACT_F}	handles for the Authenticated Countdown Timers
#TPM_RC_VALUE	response code returned when the unmarshaling of this type fails

9.27 TPMI_ALG_HASH

A TPMI_ALG_HASH is an interface type of all the hash algorithms implemented on a specific TPM. The selector in Table 65 indicates all of the hash algorithms that have an algorithm ID assigned by the TCG and does not indicate the algorithms that will be accepted by a TPM.

NOTE When implemented, each of the algorithm entries is delimited by #ifdef and #endif so that, if the algorithm is not implemented in a specific TPM, that algorithm is not included in the interface type.

Table 65 — Definition of (TPM_ALG_ID) TPMI_ALG_HASH Type

Values	Comments
TPM_ALG_!ALG.H	all hash algorithms defined by the TCG
+TPM_ALG_NULL	
#TPM_RC_HASH	

9.28 TPMI_ALG_ASYM (Asymmetric Algorithms)

A TPMI_ALG_ASYM is an interface type of all the asymmetric algorithms implemented on a specific TPM. Table 66 lists each of the asymmetric algorithms that have an algorithm ID assigned by the TCG.

Table 66 — Definition of (TPM_ALG_ID) TPMI_ALG_ASYM Type

Values	Comments
TPM_ALG_!ALG.AO	all asymmetric object types
+TPM_ALG_NULL	
#TPM_RC_ASYMMETRIC	

 Copyright © TCG 2006-2020

9.29 TPMI_ALG_SYM (Symmetric Algorithms)

A TPMI_ALG_SYM is an interface type of all the symmetric algorithms that have an algorithm ID assigned by the TCG and are implemented on the TPM.

NOTE The validation code produced by an example script will produce a CASE statement with a case for each of the values in the "Values" column. The case for a value is delimited by a #ifdef/#endif pair so that if the algorithm is not implemented on the TPM, then the case for the algorithm is not generated, and use of the algorithm will cause a TPM error (TPM_RC_SYMMETRIC).

Table 67 — Definition of (TPM_ALG_ID) TPMI_ALG_SYM Type

Values	Comments
TPM_ALG_!ALG.S	all symmetric block ciphers
TPM_ALG_XOR	required
+TPM_ALG_NULL	required to be present in all versions of this table
#TPM_RC_SYMMETRIC	

9.30 TPMI_ALG_SYM_OBJECT

A TPMI_ALG_SYM_OBJECT is an interface type of all the TCG-defined symmetric algorithms that may be used as companion symmetric encryption algorithm for an asymmetric object. All algorithms in this list shall be block ciphers usable in Cipher Feedback (CFB).

NOTE TPM_ALG_XOR is not allowed in this list.

Table 68 — Definition of (TPM_ALG_ID) TPMI_ALG_SYM_OBJECT Type

Values	Comments
TPM_ALG_!ALG.S	all symmetric block ciphers
+TPM_ALG_NULL	required to be present in all versions of this table
#TPM_RC_SYMMETRIC	

9.31 TPMI_ALG_SYM_MODE

A TPMI_ALG_SYM_MODE is an interface type of all the TCG-defined block-cipher modes of operation.

Table 69 — Definition of (TPM_ALG_ID) TPMI_ALG_SYM_MODE Type

Values	Comments
TPM_ALG_!ALG.SE	all symmetric block cipher encryption/decryption modes
TPM_ALG_!ALG.SX	all symmetric block cipher MAC modes
+TPM_ALG_NULL	
#TPM_RC_MODE	

 Copyright © TCG 2006-2020

9.32 TPMI_ALG_KDF (Key and Mask Generation Functions)

A TPMI_ALG_KDF is an interface type of all the key derivation functions implemented on a specific TPM.

Table 70 — Definition of (TPM_ALG_ID) TPMI_ALG_KDF Type

Values	Comments
TPM_ALG_!ALG.HM	all defined hash-based key and mask generation functions
+TPM_ALG_NULL	
#TPM_RC_KDF	

9.33 TPMI_ALG_SIG_SCHEME

This is the definition of the interface type for any signature scheme.

Table 71 — Definition of (TPM_ALG_ID) TPMI_ALG_SIG_SCHEME Type

Values	Comments
TPM_ALG_!ALG.ax	all asymmetric signing schemes including anonymous schemes
TPM_ALG_HMAC	present on all TPM
+TPM_ALG_NULL	
#TPM_RC_SCHEME	response code when a signature scheme is not correct

9.34 TPMI_ECC_KEY_EXCHANGE

This is the definition of the interface type for an ECC key exchange scheme.

NOTE Because of the "{ECC}" in the table title, the only values in this table will be those that are dependent on ECC being implemented, even if they otherwise have the correct type attributes.

Table 72 — Definition of (TPM_ALG_ID){ECC} TPMI_ECC_KEY_EXCHANGE Type

Values	Comments
TPM_ALG_!ALG.AM	any ECC key exchange method
TPM_ALG_SM2	SM2 is typed as signing but may be used as a key-exchange protocol
+TPM_ALG_NULL	
#TPM_RC_SCHEME	response code when a key exchange scheme is not correct

 Copyright © TCG 2006-2020

9.35 TPMI_ST_COMMAND_TAG

This interface type is used for the command tags.

The response code for a bad command tag has the same value as the TPM 1.2 response code (TPM_BAD_TAG). This value is used in case the software is not compatible with this specification and an unexpected response code might have unexpected side effects.

Table 73 — Definition of (TPM_ST) TPMI_ST_COMMAND_TAG Type

Values	Comments
TPM_ST_NO_SESSIONS	
TPM_ST_SESSIONS	
#TPM_RC_BAD_TAG	

9.36 TPMI_ALG_MAC_SCHEME

A TPMI_ALG_MAC_SCHEME is an interface type of all the TCG-defined symmetric algorithms that may be used as companion symmetric! signing algorithm.

Table 74 — Definition of (TPM_ALG_ID) TPMI_ALG_MAC_SCHEME Type

Values	Comments
TPM_ALG_!ALG.SX	all symmetric block cipher MAC algorithms
TPM_ALG_!ALG.H	all hash algorithms defined by the TCG
+TPM_ALG_NULL	required to be present in all versions of this table
#TPM_RC_SYMMETRIC	

9.37 TPMI_ALG_CIPHER_MODE

A TPMI_ALG_CIPHER_MODE is an interface type of all the symmetric block cipher, encryption/decryption modes that are listed in the TCG algorithm registry.

Table 75 — Definition of (TPM_ALG_ID) TPMI_ALG_CIPHER_MODE Type

Values	Comments
TPM_ALG_!ALG.SE	all symmetric block cipher algorithms
+TPM_ALG_NULL	required to be present in all versions of this table
#TPM_RC_MODE	

 Copyright © TCG 2006-2020

10 Structure Definitions

10.1 TPMS_EMPTY

This structure is used as a placeholder. In some cases, a union will have a selector value with no data to unmarshal when that type is selected. Rather than leave the entry empty, TPMS_EMPTY may be selected.

NOTE The tool chain will special case this structure and create the marshaling and unmarshaling code for this structure but not create a type definition. The unmarshaling code for this structure will return TPM_RC_SUCCESS and the marshaling code will return 0.

Table 76 — Definition of TPMS_EMPTY Structure <IN/OUT>

Parameter	Type	Description
		a structure with no member

10.2 TPMS_ALGORITHM_DESCRIPTION

This structure is a return value for a TPM2_GetCapability() that reads the installed algorithms.

Table 77 — Definition of TPMS_ALGORITHM_DESCRIPTION Structure <OUT>

Parameter	Type	Description
alg	TPM_ALG_ID	an algorithm
attributes	TPMA_ALGORITHM	the attributes of the algorithm

10.3 Hash/Digest Structures

10.3.1 TPMU_HA (Hash)

A TPMU_HA is a union of all the hash algorithms implemented on a TPM.

NOTE 1 The !ALG.H and !ALG.H values represent all algorithms defined in the TCG registry as being type “H”.

NOTE 2 If processed by an automated tool, each entry of the table should be qualified (with #ifdef/#endif) so that if the hash algorithm is not implemented on the TPM, the parameter associated with that hash is not present. This will keep the union from being larger than the largest digest of a hash implemented on that TPM.

Table 78 — Definition of TPMU_HA Union <IN/OUT >

Parameter	Type	Selector	Description
!ALG.H [!ALG.H_DIGEST_SIZE]	BYTE	TPM_ALG_!ALG.H	all hashes
null		TPM_ALG_NULL	

Level 00 Revision 01.59 Copyright © TCG 2006-2020 November 8, 2019

10.3.2 TPMT_HA

Table 79 shows the basic hash-agile structure used in this specification. To handle hash agility, this structure uses the *hashAlg* parameter to indicate the algorithm used to compute the digest and, by implication, the size of the digest.

When transmitted, only the number of octets indicated by *hashAlg* is sent.

NOTE In the reference code, when a TPMT_HA is allocated, the digest field is large enough to support the largest hash algorithm in the TPMU_HA union.

Table 79 — Definition of TPMT_HA Structure <IN/OUT>

Parameter	Type	Description
hashAlg	+TPMI_ALG_HASH	selector of the hash contained in the *digest* that implies the size of the *digest* NOTE The leading "+" on the type indicates that this structure should pass an indication to the unmarshaling function for TPMI_ALG_HASH so that TPM_ALG_NULL will be allowed if a use of a TPMT_HA allows TPM_ALG_NULL.
[hashAlg] digest	TPMU_HA	the digest data

10.4 Sized Buffers

10.4.1 Introduction

The "TPM2B_" prefix is used for a structure that has a size field followed by a data buffer with the indicated number of octets. The *size* field is 16 bits.

When the type of the second parameter in a TPM2B_ structure is BYTE, the TPM shall unmarshal the indicated number of octets, which may be zero.

When the type of the second parameter in the TPM2B_ structure is not BYTE, the value of the *size* field shall either be zero indicating that no structure is to be unmarshaled; or it shall be identical to the number of octets unmarshaled for the second parameter.

NOTE 1 If the TPM2B_ defines a structure and not an array of octets, then the structure is self-describing and the TPM will be able to determine how many octets are in the structure when it is unmarshaled. If that number of octets is not equal to the size parameter, then it is an error.

NOTE 2 The reason that a structure may be put into a TPM2B_ is that the parts of the structure may be handled as separate opaque blocks by the application/system software. Rather than require that all of the structures in a command or response be marshaled or unmarshaled sequentially, the size field allows the structure to be manipulated as an opaque block. Placing a structure in a TPM2B_ also makes it possible to use parameter encryption on the structure.

If a TPM2B_ is encrypted, the TPM will encrypt/decrypt the data field of the TPM2B_ but not the *size* parameter. The TPM will encrypt/decrypt the number of octets indicated by the *size* field.

NOTE 3 In the reference implementation, a TPM2B type is defined that is a 16-bit size field followed by a single byte of data. The TPM2B_ is then defined as a union that contains a TPM2B (union member 'b') and the structure in the definition table (union member 't'). This union is used for internally generated structures so that there is a way to define a structure of the correct size (forced by the 't' member) while giving a way to pass the structure generically as a 'b'. Most function calls use the 't' member so that the compiler will generate a warning if there is a type error (a TPM2B_ of the wrong type). Having the type checked helps avoid many issues with buffer overflow caused by a too small buffer being passed to a function.

 Copyright © TCG 2006-2020

10.4.2 TPM2B_DIGEST

This structure is used for a sized buffer that cannot be larger than the largest digest produced by any hash algorithm implemented on the TPM.

As with all sized buffers, the size is checked to see if it is within the prescribed range. If not, the response code is TPM_RC_SIZE.

NOTE For any structure, like the one below, that contains an implied size check, it is implied that TPM_RC_SIZE is a possible response code and the response code will not be listed in the table.

Table 80 — Definition of TPM2B_DIGEST Structure

Parameter	Type	Description
size	UINT16	size in octets of the *buffer* field; may be 0
buffer[size]{:sizeof(TPMU_HA)}	BYTE	the buffer area that can be no larger than a digest

10.4.3 TPM2B_DATA

This structure is used for a data buffer that is required to be no larger than the size of the Name of an object.

Table 81 — Definition of TPM2B_DATA Structure

Parameter	Type	Description
size	UINT16	size in octets of the *buffer* field; may be 0
buffer[size]{:sizeof(TPMT_HA)}	BYTE	

10.4.4 TPM2B_NONCE

Table 82 — Definition of Types for TPM2B_NONCE

Type	Name	Description
TPM2B_DIGEST	TPM2B_NONCE	size limited to the same as the digest structure

10.4.5 TPM2B_AUTH

This structure is used for an authorization value and limits an *authValue* to being no larger than the largest digest produced by a TPM. In order to ensure consistency within an object, the *authValue* may be no larger than the size of the digest produced by the object's *nameAlg*. This ensures that any TPM that can load the object will be able to handle the *authValue* of the object.

Table 83 — Definition of Types for TPM2B_AUTH

Type	Name	Description
TPM2B_DIGEST	TPM2B_AUTH	size limited to the same as the digest structure

 Copyright © TCG 2006-2020

10.4.6 TPM2B_OPERAND

This type is a sized buffer that can hold an operand for a comparison with an NV Index location. The maximum size of the operand is implementation dependent but a TPM is required to support an operand size that is at least as big as the digest produced by any of the hash algorithms implemented on the TPM.

Table 84 — Definition of Types for TPM2B_OPERAND

Type	Name	Description
TPM2B_DIGEST	TPM2B_OPERAND	size limited to the same as the digest structure

10.4.7 TPM2B_EVENT

This type is a sized buffer that can hold event data.

Table 85 — Definition of TPM2B_EVENT Structure

Parameter	Type	Description
size	UINT16	size of the operand *buffer*
buffer [size] {:1024}	BYTE	the operand

10.4.8 TPM2B_MAX_BUFFER

This type is a sized buffer that can hold a maximally sized buffer for commands that use a large data buffer such as TPM2_Hash(), TPM2_SequenceUpdate(), or TPM2_FieldUpgradeData().

NOTE The above list is not comprehensive and other commands may use this buffer type.

MAX_DIGEST_BUFFER is TPM-dependent but is required to be at least 1,024.

Table 86 — Definition of TPM2B_MAX_BUFFER Structure

Parameter	Type	Description
size	UINT16	size of the buffer
buffer [size] {:MAX_DIGEST_BUFFER}	BYTE	the operand

10.4.9 TPM2B_MAX_NV_BUFFER

This type is a sized buffer that can hold a maximally sized buffer for NV data commands such as TPM2_NV_Read(), TPM2_NV_Write(), and TPM2_NV_Certify().

Table 87 — Definition of TPM2B_MAX_NV_BUFFER Structure

Parameter	Type	Description
size	UINT16	size of the buffer
buffer [size] {:MAX_NV_BUFFER_SIZE}	BYTE	the operand NOTE MAX_NV_BUFFER_SIZE is TPM-dependent

 Copyright © TCG 2006-2020

10.4.10 TPM2B_TIMEOUT

This TPM-dependent structure is used to provide the timeout value for an authorization. The *size* shall be 8 or less.

Table 88 — Definition of TPM2B_TIMEOUT Structure

Type	Name	Description
size	UINT16	size of the timeout value
buffer[size]{:sizeof(UINT64)}	BYTE	the timeout value

NOTE In the reference implementation the MSb is used as a flag to indicate whether a ticket expires on TPM Reset or TPM Restart.

10.4.11 TPM2B_IV

This structure is used for passing an initial value for a symmetric block cipher to or from the TPM. The size is set to be the largest block size of any implemented symmetric cipher implemented on the TPM.

Table 89 — Definition of TPM2B_IV Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	size of the IV value This value is fixed for a TPM implementation.
buffer[size]{:MAX_SYM_BLOCK_SIZE}	BYTE	the IV value

10.5 Names

10.5.1 Introduction

The Name of an entity is used in place of the handle in authorization computations. The substitution occurs in *cpHash* and *policyHash* computations.

For an entity that is defined by a public area (objects and NV Indexes), the Name is the hash of the public structure that defines the entity. The hash is done using the *nameAlg* of the entity.

NOTE For an object, a TPMT_PUBLIC defines the entity. For an NV Index, a TPMS_NV_PUBLIC defines the entity.

For entities not defined by a public area, the Name is the handle that is used to refer to the entity.

10.5.2 TPMU_NAME

Table 90 — Definition of TPMU_NAME Union <>

Parameter	Type	Selector	Description
digest	TPMT_HA		when the Name is a digest
handle	TPM_HANDLE		when the Name is a handle

 Copyright © TCG 2006-2020

10.5.3 TPM2B_NAME

This buffer holds a Name for any entity type.

The type of Name in the structure is determined by context and the *size* parameter. If *size* is four, then the Name is a handle. If *size* is zero, then no Name is present. Otherwise, the size shall be the size of a TPM_ALG_ID plus the size of the digest produced by the indicated hash algorithm.

Table 91 — Definition of TPM2B_NAME Structure

Parameter	Type	Description
size	UINT16	size of the Name structure
name[size]{:sizeof(TPMU_NAME)}	BYTE	the Name structure

10.6 PCR Structures

10.6.1 TPMS_PCR_SELECT

This structure provides a standard method of specifying a list of PCR.

PCR numbering starts at zero.

pcrSelect is an array of octets. The octet containing the bit corresponding to a specific PCR is found by dividing the PCR number by 8.

EXAMPLE 1 The bit in *pcrSelect* corresponding to PCR 19 is in *pcrSelect* [2] (19/8 = 2).

The least significant bit in a octet is bit number 0. The bit in the octet associated with a PCR is the remainder after division by 8.

EXAMPLE 2 The bit in *pcrSelect* [2] corresponding to PCR 19 is bit 3 (19 mod 8). If *sizeofSelect* is 3, then the *pcrSelect* array that would specify PCR 19 and no other PCR is 00 00 08_{16}.

Each bit in *pcrSelect* indicates whether the corresponding PCR is selected (1) or not (0). If the *pcrSelect* is all zero bits, then no PCR is selected.

sizeofSelect indicates the number of octets in *pcrSelect*. The allowable value for *sizeofSelect* is determined by the number of PCR required by the applicable platform-specific specification and the number of PCR implemented in the TPM. The minimum value for *sizeofSelect* is:

$$PCR_SELECT_MIN \coloneqq (PLATFORM_PCR + 7) / 8 \quad (1)$$

where

PLATFORM_PCR the number of PCR required by the platform-specific specification

The maximum value for sizeofSelect is:

$$PCR_SELECT_MAX \coloneqq (IMPLEMENTATION_PCR + 7) / 8 \quad (2)$$

where

IMPLEMENTATION_PCR the number of PCR implemented on the TPM

 Copyright © TCG 2006-2020

If the TPM implements more PCR than there are bits in *pcrSelect*, the additional PCR are not selected.

EXAMPLE 3 If the applicable platform-specific specification requires that the TPM have a minimum of 24 PCR but the TPM implements 32, then a PCR select of 3 octets would imply that PCR 24-31 are not selected.

Table 92 — Definition of TPMS_PCR_SELECT Structure

Parameter	Type	Description
sizeofSelect {PCR_SELECT_MIN:}	UINT8	the size in octets of the *pcrSelect* array
pcrSelect [sizeofSelect] {:PCR_SELECT_MAX}	BYTE	the bit map of selected PCR
#TPM_RC_VALUE		

10.6.2 TPMS_PCR_SELECTION

Table 93 — Definition of TPMS_PCR_SELECTION Structure

Parameter	Type	Description
hash	TPMI_ALG_HASH	the hash algorithm associated with the selection
sizeofSelect {PCR_SELECT_MIN:}	UINT8	the size in octets of the *pcrSelect* array
pcrSelect [sizeofSelect] {:PCR_SELECT_MAX}	BYTE	the bit map of selected PCR
#TPM_RC_VALUE		

10.7 Tickets

10.7.1 Introduction

Tickets are evidence that the TPM has previously processed some information. A ticket is an HMAC over the data using a secret key known only to the TPM. A ticket is a way to expand the state memory of the TPM. A ticket is only usable by the TPM that produced it.

The formulations for tickets shown in 10.7 are to be used by a TPM that is compliant with this specification.

The method of creating the ticket data is:

$$\mathbf{HMAC}_{contexAlg}(proof, (ticketType \mid\mid param \{ \mid\mid param \{...\}\})) \quad (3)$$

where

$\mathbf{HMAC}_{contexAlg}()$ an HMAC using the hash used for context integrity

$proof$ a TPM secret value (depends on hierarchy)

$ticketType$ a value to differentiate the tickets

$param$ one or more values that were checked by the TPM

 Copyright © TCG 2006-2020

The proof value used for each hierarchy is shown in Table 94.

Table 94 — Values for *proof* Used in Tickets

Hierarchy	proof	Description
Null	nullProof	a value that changes with every TPM Reset
Platform	phProof	a value that changes with each change of the PPS
Owner	shProof	a value that changes with each change of the SPS
Endorsement	ehProof	a value that changes with each change of either the EPS or SPS

The format for a ticket is shown in Table 95. This is a template for the tickets shown in the remainder of this clause 10.7.

Table 95 — General Format of a Ticket

Parameter	Type	Description
tag	TPM_ST	structure tag indicating the type of the ticket
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy of the proof value
digest	TPM2B_DIGEST	the HMAC over the ticket-specific data

10.7.2 A NULL Ticket

When a command requires a ticket and no ticket is available, the caller is required to provide a structure with a ticket *tag* that is correct for the context. The *hierarchy* shall be set to TPM_RH_NULL, and *digest* shall be the Empty Buffer (a buffer with a size field of zero). This construct is the NULL Ticket. When a response indicates that a ticket is returned, the TPM may return a NULL Ticket.

NOTE Because each use of a ticket requires that the structure tag for the ticket be appropriate for the use, there is no single representation of a NULL Ticket that will work in all circumstances. Minimally, a NULL ticket will have a structure type that is appropriate for the context.

10.7.3 TPMT_TK_CREATION

This ticket is produced by TPM2_Create() or TPM2_CreatePrimary(). It is used to bind the creation data to the object to which it applies. The ticket is computed by

$$\mathbf{HMAC}_{contextAlg}(proof, (\text{TPM_ST_CREATION} \mathbin{||} name \mathbin{||} \mathbf{H}_{nameAlg}(\text{TPMS_CREATION_DATA}))) \quad (4)$$

where

$\mathbf{HMAC}_{contextAlg}()$	an HMAC using the context integrity hash algorithm
$proof$	a TPM secret value associated with the hierarchy associated with name
TPM_ST_CREATION	a value used to ensure that the ticket is properly used
$name$	the Name of the object to which the creation data is to be associated
$\mathbf{H}_{nameAlg}()$	hash using the *nameAlg* of the created object
TPMS_CREATION_DATA	the creation data structure associated with name

 Copyright © TCG 2006-2020

Table 96 — Definition of TPMT_TK_CREATION Structure

Parameter	Type	Description
tag {TPM_ST_CREATION}	TPM_ST	ticket structure tag
#TPM_RC_TAG		error returned when *tag* is not TPM_ST_CREATION
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy containing *name*
digest	TPM2B_DIGEST	This shall be the HMAC produced using a proof value of *hierarchy*.

EXAMPLE A NULL Creation Ticket is the tuple <TPM_ST_CREATION, TPM_RH_NULL, 0x0000>.

10.7.4 TPMT_TK_VERIFIED

This ticket is produced by TPM2_VerifySignature(). This formulation is used for multiple ticket uses. The ticket provides evidence that the TPM has validated that a digest was signed by a key with the Name of keyName. The ticket is computed by

$$\mathbf{HMAC}_{contextAlg}(proof, (\text{TPM_ST_VERIFIED} \mathbin{||} digest \mathbin{||} keyName)) \tag{5}$$

where

$\mathbf{HMAC}_{contextAlg}()$	an HMAC using the context integrity hash
$proof$	a TPM secret value associated with the hierarchy associated with *keyName*
TPM_ST_VERIFIED	a value used to ensure that the ticket is properly used
$digest$	the signed digest
$keyName$	Name of the key that signed digest

Table 97 — Definition of TPMT_TK_VERIFIED Structure

Parameter	Type	Description
tag {TPM_ST_VERIFIED}	TPM_ST	ticket structure tag
#TPM_RC_TAG		error returned when *tag* is not TPM_ST_VERIFIED
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy containing *keyName*
digest	TPM2B_DIGEST	This shall be the HMAC produced using a proof value of *hierarchy*.

EXAMPLE A NULL Verified Ticket is the tuple <TPM_ST_VERIFIED, TPM_RH_NULL, 0x0000>.

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

10.7.5 TPMT_TK_AUTH

This ticket is produced by TPM2_PolicySigned() and TPM2_PolicySecret() when the authorization has an expiration time. If *nonceTPM* was provided in the policy command, t*he* ticket is computed by

$$\mathbf{HMAC}_{contextAlg}(proof, (\text{TPM_ST_AUTH_xxx} \mid\mid cpHash \mid\mid policyRef \mid\mid authName \mid\mid timeout \mid\mid [timeEpoch] \mid\mid [resetCount])) \quad (6)$$

where

$\mathbf{HMAC}_{contextAlg}()$	an HMAC using the context integrity hash
$proof$	a TPM secret value associated with the hierarchy of the object associated with *authName*
TPM_ST_AUTH_xxx	either TPM_ST_AUTH_SIGNED or TPM_ST_AUTH_SECRET; used to ensure that the ticket is properly used
$cpHash$	optional hash of the authorized command
$policyRef$	optional reference to a policy value
$authName$	Name of the object that signed the authorization
$timeout$	implementation-specific value indicating when the authorization expires
$timeEpoch$	implementation-specific representation of the $timeEpoch$ at the time the ticket was created

NOTE 1 Not included if *timeout* is zero.

$resetCount$	implementation-specific representation of the TPM's *totalResetCount*

NOTE 2 Not included it *timeout* is zero or if *nonceTPM* was include in the authorization.

Table 98 — Definition of TPMT_TK_AUTH Structure

Parameter	Type	Description
tag {TPM_ST_AUTH_SIGNED, TPM_ST_AUTH_SECRET}	TPM_ST	ticket structure tag
#TPM_RC_TAG		error returned when *tag* is not TPM_ST_AUTH
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy of the object used to produce the ticket
digest	TPM2B_DIGEST	This shall be the HMAC produced using a proof value of *hierarchy*.

EXAMPLE A NULL Auth Ticket is the tuple <TPM_ST_AUTH_SIGNED, TPM_RH_NULL, 0x0000> or the tuple <TPM_ST_AUTH_SIGNED, TPM_RH_NULL, 0x0000>

 Copyright © TCG 2006-2020

10.7.6 TPMT_TK_HASHCHECK

This ticket is produced by TPM2_SequenceComplete() or TPM2_Hash() when the message that was digested did not start with TPM_GENERATED_VALUE. The ticket is computed by

$$\mathbf{HMAC}_{contexAlg}(proof, (\text{TPM_ST_HASHCHECK} \mid\mid digest)) \quad (7)$$

where

$\mathbf{HMAC}_{contexAlg}\,()$	an HMAC using the context integrity hash
$proof$	a TPM secret value associated with the hierarchy indicated by the command
TPM_ST_HASHCHECK	a value used to ensure that the ticket is properly used
$digest$	the digest of the data

Table 99 — Definition of TPMT_TK_HASHCHECK Structure

Parameter	Type	Description
tag {TPM_ST_HASHCHECK}	TPM_ST	ticket structure tag
#TPM_RC_TAG		error returned when is not TPM_ST_HASHCHECK
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy
digest	TPM2B_DIGEST	This shall be the HMAC produced using a proof value of *hierarchy*.

10.8 Property Structures

10.8.1 TPMS_ALG_PROPERTY

This structure is used to report the properties of an algorithm identifier. It is returned in response to a TPM2_GetCapability() with *capability* = TPM_CAP_ALG.

Table 100 — Definition of TPMS_ALG_PROPERTY Structure <OUT>

Parameter	Type	Description
alg	TPM_ALG_ID	an algorithm identifier
algProperties	TPMA_ALGORITHM	the attributes of the algorithm

10.8.2 TPMS_TAGGED_PROPERTY

This structure is used to report the properties that are UINT32 values. It is returned in response to a TPM2_GetCapability().

Table 101 — Definition of TPMS_TAGGED_PROPERTY Structure <OUT>

Parameter	Type	Description
property	TPM_PT	a property identifier
value	UINT32	the value of the property

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

10.8.3 TPMS_TAGGED_PCR_SELECT

This structure is used in TPM2_GetCapability() to return the attributes of the PCR.

Table 102 — Definition of TPMS_TAGGED_PCR_SELECT Structure <OUT>

Parameter	Type	Description
tag	TPM_PT_PCR	the property identifier
sizeofSelect {PCR_SELECT_MIN:}	UINT8	the size in octets of the *pcrSelect* array
pcrSelect [sizeofSelect] {:PCR_SELECT_MAX}	BYTE	the bit map of PCR with the identified property

10.8.4 TPMS_TAGGED_POLICY

This structure is used in TPM2_GetCapability() to return the policy associated with a permanent handle.

Table 103 — Definition of TPMS_TAGGED_POLICY Structure <OUT>

Parameter	Type	Description
handle	TPM_HANDLE	a permanent handle
policyHash	TPMT_HA	the policy algorithm and hash

10.8.5 TPMS_ACT_DATA

This structure is used in TPM2_GetCapability() to return the ACT data.

Table 104 — Definition of TPMS_ACT_DATA Structure <OUT>

Parameter	Type	Description
handle	TPM_HANDLE	a permanent handle
timeout	UINT32	the current timeout of the ACT
attributes	TPMA_ACT	the state of the ACT

 Copyright © TCG 2006-2020

10.9 Lists

10.9.1 TPML_CC

A list of command codes may be input to the TPM or returned by the TPM depending on the command.

Table 105 — Definition of TPML_CC Structure

Parameter	Type	Description
count	UINT32	number of commands in the *commandCode* list; may be 0
commandCodes[count]{:MAX_CAP_CC}	TPM_CC	a list of command codes The maximum only applies to a command code list in a command. The response size is limited only by the size of the parameter buffer.
#TPM_RC_SIZE		response code when count is greater than the maximum allowed list size

10.9.2 TPML_CCA

This list is only used in TPM2_GetCapability(capability = TPM_CAP_COMMANDS).

The values in the list are returned in TPMA_CC->*commandIndex* order (see Table 37) with vendor-specific commands returned after other commands. Because of the other attributes, the commands may not be returned in strict numerical order.

Table 106 — Definition of TPML_CCA Structure <OUT>

Parameter	Type	Description
count	UINT32	number of values in the *commandAttributes* list; may be 0
commandAttributes[count]{:MAX_CAP_CC}	TPMA_CC	a list of command codes attributes

10.9.3 TPML_ALG

This list is returned by TPM2_IncrementalSelfTest().

Table 107 — Definition of TPML_ALG Structure

Parameter	Type	Description
count	UINT32	number of algorithms in the *algorithms* list; may be 0
algorithms[count]{:MAX_ALG_LIST_SIZE}	TPM_ALG_ID	a list of algorithm IDs The maximum only applies to an algorithm list in a command. The response size is limited only by the size of the parameter buffer.
#TPM_RC_SIZE		response code when *count* is greater than the maximum allowed list size

 Copyright © TCG 2006-2020

10.9.4 TPML_HANDLE

This structure is used when the TPM returns a list of loaded handles when the *capability* in TPM2_GetCapability() is TPM_CAP_HANDLE.

NOTE 1 MAX_CAP_HANDLES = (MAX_CAP_DATA / sizeof(TPM_HANDLE))

NOTE 2 This list is not used as input to the TPM.

Table 108 — Definition of TPML_HANDLE Structure <OUT>

Name	Type	Description
count	UINT32	the number of handles in the list may have a value of 0
handle[count]{: MAX_CAP_HANDLES}	TPM_HANDLE	an array of handles
#TPM_RC_SIZE		response code when *count* is greater than the maximum allowed list size

10.9.5 TPML_DIGEST

This list is used to convey a list of digest values. This type is used in TPM2_PolicyOR() and in TPM2_PCR_Read().

Table 109 — Definition of TPML_DIGEST Structure

Parameter	Type	Description
count {2:}	UINT32	number of digests in the list, minimum is two for TPM2_PolicyOR().
digests[count]{:8}	TPM2B_DIGEST	a list of digests For TPM2_PolicyOR(), all digests will have been computed using the digest of the policy session. For TPM2_PCR_Read(), each digest will be the size of the digest for the bank containing the PCR.
#TPM_RC_SIZE		response code when *count* is not at least two or is greater than eight

 Copyright © TCG 2006-2020

10.9.6 TPML_DIGEST_VALUES

This list is used to convey a list of digest values. This type is returned by TPM2_PCR_Event() and TPM2_EventSequenceComplete() and is an input for TPM2_PCR_Extend().

NOTE 1 This construct limits the number of hashes in the list to the number of digests implemented in the TPM rather than the number of PCR banks. This allows extra values to appear in a call to TPM2_PCR_Extend().

NOTE 2 The digest for an unimplemented hash algorithm may not be in a list because the TPM may not recognize the algorithm as being a hash and it may not know the digest size.

Table 110 — Definition of TPML_DIGEST_VALUES Structure

Parameter	Type	Description
count	UINT32	number of digests in the list
digests[count]{:HASH_COUNT}	TPMT_HA	a list of tagged digests
#TPM_RC_SIZE		response code when *count* is greater than the possible number of banks

10.9.7 TPML_PCR_SELECTION

This list is used to indicate the PCR that are included in a selection when more than one PCR value may be selected.

This structure is an input parameter to TPM2_PolicyPCR() to indicate the PCR that will be included in the digest of PCR for the authorization. The structure is used in TPM2_PCR_Read() command to indicate the PCR values to be returned and in the response to indicate which PCR are included in the list of returned digests. The structure is an output parameter from TPM2_Create() and indicates the PCR used in the digest of the PCR state when the object was created. The structure is also contained in the attestation structure of TPM2_Quote().

When this structure is used to select PCR to be included in a digest, the selected PCR are concatenated to create a “message” containing all of the PCR, and then the message is hashed using the context-specific hash algorithm.

Table 111 — Definition of TPML_PCR_SELECTION Structure

Parameter	Type	Description
count	UINT32	number of selection structures A value of zero is allowed.
pcrSelections[count]{:HASH_COUNT}	TPMS_PCR_SELECTION	list of selections
#TPM_RC_SIZE		response code when *count* is greater than the possible number of banks

10.9.8 TPML_ALG_PROPERTY

This list is used to report on a list of algorithm attributes. It is returned in a TPM2_GetCapability().

NOTE MAX_CAP_ALGS = MAX_CAP_DATA / sizeof(TPMS_ALG_PROPERTY).

 Copyright © TCG 2006-2020

Table 112 — Definition of TPML_ALG_PROPERTY Structure <OUT>

Parameter	Type	Description
count	UINT32	number of algorithm properties structures A value of zero is allowed.
algProperties[count]{:MAX_CAP_ALGS}	TPMS_ALG_PROPERTY	list of properties

10.9.9 TPML_TAGGED_TPM_PROPERTY

This list is used to report on a list of properties that are TPMS_TAGGED_PROPERTY values. It is returned by a TPM2_GetCapability().

NOTE MAX_TPM_PROPERTIES = MAX_CAP_DATA / sizeof(TPMS_TAGGED_PROPERTY).

Table 113 — Definition of TPML_TAGGED_TPM_PROPERTY Structure <OUT>

Parameter	Type	Description
count	UINT32	number of properties A value of zero is allowed.
tpmProperty[count]{:MAX_TPM_PROPERTIES}	TPMS_TAGGED_PROPERTY	an array of tagged properties

10.9.10 TPML_TAGGED_PCR_PROPERTY

This list is used to report on a list of properties that are TPMS_PCR_SELECT values. It is returned by a TPM2_GetCapability().

NOTE MAX_PCR_PROPERTIES = MAX_CAP_DATA / sizeof(TPMS_TAGGED_PCR_SELECT).

Table 114 — Definition of TPML_TAGGED_PCR_PROPERTY Structure <OUT>

Parameter	Type	Description
count	UINT32	number of properties A value of zero is allowed.
pcrProperty[count]{:MAX_PCR_PROPERTIES}	TPMS_TAGGED_PCR_SELECT	a tagged PCR selection

10.9.11 TPML_ECC_CURVE

This list is used to report the ECC curve ID values supported by the TPM. It is returned by a TPM2_GetCapability().

NOTE MAX_ECC_CURVES = MAX_CAP_DATA / sizeof(TPM_ECC_CURVE).

Table 115 — Definition of {ECC} TPML_ECC_CURVE Structure <OUT>

Parameter	Type	Description
count	UINT32	number of curves A value of zero is allowed.
eccCurves[count]{:MAX_ECC_CURVES}	TPM_ECC_CURVE	array of ECC curve identifiers

 Copyright © TCG 2006-2020

10.9.12 TPML_TAGGED_POLICY

This list is used to report the authorization policy values for permanent handles. This is list may be generated by TPM2_GetCapabiltiy(). A permanent handle that cannot have a policy is not included in the list.

NOTE MAX_TAGGED_POLICIES = MAX_CAP_DATA / sizeof(TPMS_TAGGED_POLICY).

Table 116 — Definition of TPML_TAGGED_POLICY Structure <OUT>

Parameter	Type	Description
count	UINT32	number of tagged policies A value of zero is allowed.
policies[count]{:MAX_TAGGED_POLICIES}	TPMS_TAGGED_POLICY	array of tagged policies

10.9.13 TPML_ACT_DATA

This list is used to report the timeout and state for the ACT. This list may be generated by TPM2_GetCapabilty(). Only implemented ACT are present in the list

NOTE MAX_ACT_DATA = MAX_CAP_DATA / sizeof(TPMS_ACT_DATA).

Table 117 — Definition of TPML_ACT_DATA Structure <OUT>

Parameter	Type	Description
count	UINT32	number of ACT instances A value of zero is allowed.
actData[count]{:MAX_ACT_DATA}	TPMS_ACT_DATA	array of ACT data

10.10 Capabilities Structures

It is required that each parameter in this union be a list (TPML).

The number of returned elements in each list is determined by the size of each list element and the maximum size set by the vendor as the capability buffer (MAX_CAP_BUFFER in TPM_PT_MAX_CAP_BUFFER). The maximum number of bytes in a list is:

```
MAX_CAP_DATA = (MAX_CAP_BUFFER – sizeof(TPM_CAP) – sizeof(UINT32)
```
(8)

The maximum number of entries is then the number of complete list elements that will fit in MAX_CAP_DATA.

EXAMPLE For a 1024-octet MAX_CAP_BUFFER a response containing a TPML_HANDLE could have (1024 - 4 – 4) / 4 = 254 handles.

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

10.10.1 TPMU_CAPABILITIES

Table 118 — Definition of TPMU_CAPABILITIES Union <OUT>

Parameter	Type	Selector	Description
algorithms	TPML_ALG_PROPERTY	TPM_CAP_ALGS	
handles	TPML_HANDLE	TPM_CAP_HANDLES	
command	TPML_CCA	TPM_CAP_COMMANDS	
ppCommands	TPML_CC	TPM_CAP_PP_COMMANDS	
auditCommands	TPML_CC	TPM_CAP_AUDIT_COMMANDS	
assignedPCR	TPML_PCR_SELECTION	TPM_CAP_PCRS	
tpmProperties	TPML_TAGGED_TPM_PROPERTY	TPM_CAP_TPM_PROPERTIES	
pcrProperties	TPML_TAGGED_PCR_PROPERTY	TPM_CAP_PCR_PROPERTIES	
eccCurves	TPML_ECC_CURVE	TPM_CAP_ECC_CURVES	TPM_ALG_ECC
authPolicies	TPML_TAGGED_POLICY	TPM_CAP_AUTH_POLICIES	
actData	TPML_ACT_DATA	TPM_CAP_ACT	

10.10.2 TPMS_CAPABILITY_DATA

This data area is returned in response to a TPM2_GetCapability().

Table 119 — Definition of TPMS_CAPABILITY_DATA Structure <OUT>

Parameter	Type	Description
capability	TPM_CAP	the capability
[capability]data	TPMU_CAPABILITIES	the capability data

 Copyright © TCG 2006-2020

10.11 Clock/Counter Structures

10.11.1 TPMS_CLOCK_INFO

This structure is used in each of the attestation commands.

Table 120 — Definition of TPMS_CLOCK_INFO Structure

Parameter	Type	Description
clock	UINT64	time value in milliseconds that advances while the TPM is powered NOTE The interpretation of the time-origin (*clock*=0) is out of the scope of this specification, although Coordinated Universal Time (UTC) is expected to be a common convention. This structure element is used to report on the TPM's Clock value. This value is reset to zero when the Storage Primary Seed is changed (TPM2_Clear()). This value may be advanced by TPM2_ClockSet().
resetCount	UINT32	number of occurrences of TPM Reset since the last TPM2_Clear()
restartCount	UINT32	number of times that TPM2_Shutdown() or _TPM_Hash_Start have occurred since the last TPM Reset or TPM2_Clear().
safe	TPMI_YES_NO	no value of *Clock* greater than the current value of *Clock* has been previously reported by the TPM. Set to YES on TPM2_Clear().

 Copyright © TCG 2006-2020

10.11.2 *Clock*

Clock is a monotonically increasing counter that advances whenever power is applied to the TPM. The value of *Clock* may be set forward with TPM2_ClockSet() if Owner Authorization or Platform Authorization is provided. The value of *Clock* is incremented each millisecond.

TPM2_Clear() will set *Clock* to zero.

Clock will be non-volatile but may have a volatile component that is updated every millisecond with the non-volatile component updated at a lower rate. The reference for the millisecond timer is the TPM oscillator. If the implementation uses a volatile component, the non-volatile component shall be updated no less frequently than every 2^{22} milliseconds (~69.9 minutes). The update rate of the non-volatile portion of *Clock* shall be reported by a TPM2_GetCapability() with *capability* = TPM_CAP_TPM_PROPERTIES and *property* = TPM_PT_CLOCK_UPDATE.

10.11.3 *ResetCount*

This counter shall increment on each TPM Reset. This counter shall be reset to zero by TPM2_Clear().

10.11.4 *RestartCount*

This counter shall increment by one for each TPM Restart or TPM Resume. The *restartCount* shall be reset to zero on a TPM Reset or TPM2_Clear().

10.11.5 *Safe*

This parameter is set to YES when the value reported in *Clock* is guaranteed to be greater than any previous value for the current Owner. It is set to NO when the value of *Clock* may have been reported in a previous attestation or access.

EXAMPLE 1 If *Safe* was NO at TPM2_Shutdown() and *Clock* does not update unless a command is received, *Safe* will be NO if a TPM2_Startup() was preceded by TPM2_Shutdown() with no intervening commands. If *Clock* updates independent of commands, the non-volatile bits of *Clock* can be updated, so *Safe* can be YES at TPM2_Startup().

EXAMPLE 2 This parameter will be YES after the non-volatile bits of *Clock* have been updated at the end of an update interval.

If a TPM implementation does not implement *Clock*, *Safe* shall always be NO and TPMS_CLOCK_INFO.*clock* shall always be zero.

This parameter will be set to YES by TPM2_Clear().

10.11.6 TPMS_TIME_INFO

This structure is used in, e.g., the TPM2_GetTime() attestation and TPM2_ReadClock().

The *Time* value reported in this structure is reset whenever power to the *Time* circuit is reestablished. If required, an implementation may reset the value of *Time* any time before the TPM returns after TPM2_Startup(). The value of *Time* shall increment continuously while power is applied to the TPM.

Table 121 — Definition of TPMS_TIME_INFO Structure

Parameter	Type	Description
time	UINT64	time in milliseconds since the *TIme* circuit was last reset This structure element is used to report on the TPM's *Time* value.
clockInfo	TPMS_CLOCK_INFO	a structure containing the clock information

 Copyright © TCG 2006-2020

10.12 TPM Attestation Structures

10.12.1 Introduction

Clause 10.12 describes the structures that are used when a TPM creates a structure to be signed. The signing structures follow a standard format TPM2B_ATTEST with case-specific information embedded.

10.12.2 TPMS_TIME_ATTEST_INFO

This structure is used when the TPM performs TPM2_GetTime.

Table 122 — Definition of TPMS_TIME_ATTEST_INFO Structure <OUT>

Parameter	Type	Description
time	TPMS_TIME_INFO	the *Time*, *Clock*, *resetCount*, *restartCount*, and *Safe* indicator
firmwareVersion	UINT64	a TPM vendor-specific value indicating the version number of the firmware

10.12.3 TPMS_CERTIFY_INFO

This is the attested data for TPM2_Certify().

Table 123 — Definition of TPMS_CERTIFY_INFO Structure <OUT>

Parameter	Type	Description
name	TPM2B_NAME	Name of the certified object
qualifiedName	TPM2B_NAME	Qualified Name of the certified object

10.12.4 TPMS_QUOTE_INFO

This is the *attested* data for TPM2_Quote().

Table 124 — Definition of TPMS_QUOTE_INFO Structure <OUT>

Parameter	Type	Description
pcrSelect	TPML_PCR_SELECTION	information on *algID*, PCR selected and digest
pcrDigest	TPM2B_DIGEST	digest of the selected PCR using the hash of the signing key

 Copyright © TCG 2006-2020

10.12.5 TPMS_COMMAND_AUDIT_INFO

This is the *attested* data for TPM2_GetCommandAuditDigest().

Table 125 — Definition of TPMS_COMMAND_AUDIT_INFO Structure <OUT>

Parameter	Type	Description
auditCounter	UINT64	the monotonic audit counter
digestAlg	TPM_ALG_ID	hash algorithm used for the command audit
auditDigest	TPM2B_DIGEST	the current value of the audit digest
commandDigest	TPM2B_DIGEST	digest of the command codes being audited using *digestAlg*

10.12.6 TPMS_SESSION_AUDIT_INFO

This is the *attested* data for TPM2_GetSessionAuditDigest().

Table 126 — Definition of TPMS_SESSION_AUDIT_INFO Structure <OUT>

Parameter	Type	Description
exclusiveSession	TPMI_YES_NO	current exclusive status of the session TRUE if all of the commands recorded in the *sessionDigest* were executed without any intervening TPM command that did not use this audit session
sessionDigest	TPM2B_DIGEST	the current value of the session audit digest

10.12.7 TPMS_CREATION_INFO

This is the *attested* data for TPM2_CertifyCreation().

Table 127 — Definition of TPMS_CREATION_INFO Structure <OUT>

Parameter	Type	Description
objectName	TPM2B_NAME	Name of the object
creationHash	TPM2B_DIGEST	creationHash

10.12.8 TPMS_NV_CERTIFY_INFO

This structure contains the Name and contents of the selected NV Index that is certified by TPM2_NV_Certify().

Table 128 — Definition of TPMS_NV_CERTIFY_INFO Structure <OUT>

Parameter	Type	Description
indexName	TPM2B_NAME	Name of the NV Index
offset	UINT16	the *offset* parameter of TPM2_NV_Certify()
nvContents	TPM2B_MAX_NV_BUFFER	contents of the NV Index

 Copyright © TCG 2006-2020

10.12.9 TPMS_NV_DIGEST_CERTIFY_INFO

This structure contains the Name and hash of the contents of the selected NV Index that is certified by TPM2_NV_Certify(). The data is hashed using hash of the signing scheme.

NOTE This structure was added in revision 01.53 to support alternate TPM2_NV_Certify() behavior.

Table 129 — Definition of TPMS_NV_DIGEST_CERTIFY_INFO Structure <OUT>

Parameter	Type	Description
indexName	TPM2B_NAME	Name of the NV Index
nvDigest	TPM2B_DIGEST	hash of the contents of the index

10.12.10 TPMI_ST_ATTEST

Table 130 — Definition of (TPM_ST) TPMI_ST_ATTEST Type <OUT>

Value	Description
TPM_ST_ATTEST_CERTIFY	generated by TPM2_Certify()
TPM_ST_ATTEST_QUOTE	generated by TPM2_Quote()
TPM_ST_ATTEST_SESSION_AUDIT	generated by TPM2_GetSessionAuditDigest()
TPM_ST_ATTEST_COMMAND_AUDIT	generated by TPM2_GetCommandAuditDigest()
TPM_ST_ATTEST_TIME	generated by TPM2_GetTime()
TPM_ST_ATTEST_CREATION	generated by TPM2_CertifyCreation()
TPM_ST_ATTEST_NV	generated by TPM2_NV_Certify()
TPM_ST_ATTEST_NV_DIGEST	generated by TPM2_NV_Certify()

10.12.11 TPMU_ATTEST

Table 131 — Definition of TPMU_ATTEST Union <OUT>

Parameter	Type	Selector
certify	TPMS_CERTIFY_INFO	TPM_ST_ATTEST_CERTIFY
creation	TPMS_CREATION_INFO	TPM_ST_ATTEST_CREATION
quote	TPMS_QUOTE_INFO	TPM_ST_ATTEST_QUOTE
commandAudit	TPMS_COMMAND_AUDIT_INFO	TPM_ST_ATTEST_COMMAND_AUDIT
sessionAudit	TPMS_SESSION_AUDIT_INFO	TPM_ST_ATTEST_SESSION_AUDIT
time	TPMS_TIME_ATTEST_INFO	TPM_ST_ATTEST_TIME
nv	TPMS_NV_CERTIFY_INFO	TPM_ST_ATTEST_NV
nvDigest	TPMS_NV_DIGEST_CERTIFY_INFO	TPM_ST_ATTEST_NV_DIGEST

Copyright © TCG 2006-2020

10.12.12 TPMS_ATTEST

This structure is used on each TPM-generated signed structure. The signature is over this structure.

When the structure is signed by a key in the Storage hierarchy, the values of *clockInfo.resetCount*, *clockInfo.restartCount*, and *firmwareVersion* are obfuscated with a per-key obfuscation value.

Table 132 — Definition of TPMS_ATTEST Structure <OUT>

Parameter	Type	Description
magic	TPM_GENERATED	the indication that this structure was created by a TPM (always TPM_GENERATED_VALUE)
type	TPMI_ST_ATTEST	type of the attestation structure
qualifiedSigner	TPM2B_NAME	Qualified Name of the signing key
extraData	TPM2B_DATA	external information supplied by caller NOTE A TPM2B_DATA structure provides room for a digest and a method indicator to indicate the components of the digest. The definition of this method indicator is outside the scope of this specification.
clockInfo	TPMS_CLOCK_INFO	Clock, resetCount, restartCount, and Safe
firmwareVersion	UINT64	TPM-vendor-specific value identifying the version number of the firmware
[type]attested	TPMU_ATTEST	the type-specific attestation information

 Copyright © TCG 2006-2020

10.12.13 TPM2B_ATTEST

This sized buffer to contain the signed structure. The *attestationData* is the signed portion of the structure. The *size* parameter is not signed.

Table 133 — Definition of TPM2B_ATTEST Structure <OUT>

Parameter	Type	Description
size	UINT16	size of the *attestationData* structure
attestationData[size]{:sizeof(TPMS_ATTEST)}	BYTE	the signed structure

10.13 Authorization Structures

10.13.1 Introduction

The structures in 10.13 are used for all authorizations. One or more of these structures will be present in a command or response that has a tag of TPM_ST_SESSIONS.

10.13.2 TPMS_AUTH_COMMAND

This is the format used for each of the authorizations in the session area of a command.

Table 134 — Definition of TPMS_AUTH_COMMAND Structure <IN>

Parameter	Type	Description
sessionHandle	TPMI_SH_AUTH_SESSION+	the session handle
nonce	TPM2B_NONCE	the session nonce, may be the Empty Buffer
sessionAttributes	TPMA_SESSION	the session attributes
hmac	TPM2B_AUTH	either an HMAC, a password, or an EmptyAuth

10.13.3 TPMS_AUTH_RESPONSE

This is the format for each of the authorizations in the session area of the response. If the TPM returns TPM_RC_SUCCESS, then the session area of the response contains the same number of authorizations as the command and the authorizations are in the same order.

Table 135 — Definition of TPMS_AUTH_RESPONSE Structure <OUT>

Parameter	Type	Description
nonce	TPM2B_NONCE	the session nonce, may be the Empty Buffer
sessionAttributes	TPMA_SESSION	the session attributes
hmac	TPM2B_AUTH	either an HMAC or an EmptyAuth

 Copyright © TCG 2006-2020

11 Algorithm Parameters and Structures

11.1 Symmetric

11.1.1 Introduction

Clause 11.1 defines the parameters and structures for describing symmetric algorithms.

11.1.2 TPMI_!ALG.S_KEY_BITS

This interface type defines the supported key sizes for a symmetric algorithm. This type is used to allow the unmarshaling routine to generate the proper validation code for the supported key sizes. An implementation that supports different key sizes would have a different set of selections.

Each implemented algorithm would have a value for the implemented key sizes for that implemented algorithm. That value would have a name in the form !ALG_KEY_SIZES_BITS where "!ALG" would represent the characteristic name of the algorithm (such as "AES).

NOTE 1 Key size is expressed in bits.

Table 136 — Definition of {!ALG.S} (TPM_KEY_BITS) TPMI_!ALG.S_KEY_BITS Type

Parameter	Description
$!ALG.S_KEY_SIZES_BITS	number of bits in the key
#TPM_RC_VALUE	error when key size is not supported

11.1.3 TPMU_SYM_KEY_BITS

This union is used to collect the symmetric encryption key sizes.

The *xor* entry is a hash algorithms selector and not a key size in bits. This overload is used in order to avoid an additional level of indirection with another union and another set of selectors.

The *xor* entry is only selected in a TPMT_SYM_DEF, which is used to select the parameter encryption value.

Table 137 — Definition of TPMU_SYM_KEY_BITS Union

Parameter	Type	Selector	Description
!ALG.S	TPMI_!ALG.S_KEY_BITS	TPM_ALG_!ALG.S	all symmetric algorithms
sym	TPM_KEY_BITS		this entry is used by the reference code to refer to the key bits field in a way that is independent of the symmetric algorithm
xor	TPMI_ALG_HASH	TPM_ALG_XOR	overload for using *xor* NOTE TPM_ALG_NULL is not allowed
null		TPM_ALG_NULL	

 Copyright © TCG 2006-2020

11.1.4 TPMU_SYM_MODE

This is the union of all modes for all symmetric algorithms.

NOTE This union definition allows the mode value in a TPMT_SYM_DEF to be empty when the selector is TPM_ALG_XOR because the XOR algorithm does not have a mode.

Table 138 — Definition of TPMU_SYM_MODE Union

Parameter	Type	Selector	Description
!ALG.S	TPMI_ALG_SYM_MODE+	TPM_ALG_!ALG.S	
sym	TPMI_ALG_SYM_MODE+		this entry is used by the reference code to refer to the mode field in a way that is independent of the symmetric algorithm
xor		TPM_ALG_XOR	no mode selector
null		TPM_ALG_NULL	no mode selector

11.1.5 TPMU_SYM_DETAILS

This union allows additional parameters to be added for a symmetric cipher. Currently, no additional parameters are required for any of the symmetric algorithms.

NOTE The “x” character in the table title will suppress generation of this type as the parser is not, at this time, able to generate the proper values (a union of all empty data types). When an algorithm is added that requires additional parameterization, the Type column will contain a value and the “x” may be removed.

Table 139 —xDefinition of TPMU_SYM_DETAILS Union

Parameter	Type	Selector	Description
!ALG.S		TPM_ALG_!ALG	
sym			this entry is used by the reference code to refer to the details field in a way that is independent of the symmetric algorithm
xor		TPM_ALG_XOR	
null		TPM_ALG_NULL	

 Copyright © TCG 2006-2020

11.1.6 TPMT_SYM_DEF

The TPMT_SYM_DEF structure is used to select an algorithm to be used for parameter encryption in those cases when different symmetric algorithms may be selected.

Table 140 — Definition of TPMT_SYM_DEF Structure

Parameter	Type	Description
algorithm	+TPMI_ALG_SYM	indicates a symmetric algorithm
[algorithm]keyBits	TPMU_SYM_KEY_BITS	a supported key size
[algorithm]mode	TPMU_SYM_MODE	the mode for the key
//[algorithm]details	TPMU_SYM_DETAILS	contains additional algorithm details NOTE This is commented out at this time as the parser may not produce the proper code for a union if none of the selectors produces any data.

11.1.7 TPMT_SYM_DEF_OBJECT

This structure is used when different symmetric block cipher (not XOR) algorithms may be selected. If the Object can be an ordinary parent (not a derivation parent), this must be the first field in the Object's parameter (see 12.2.3.7) field.

Table 141 — Definition of TPMT_SYM_DEF_OBJECT Structure

Parameter	Type	Description
algorithm	+TPMI_ALG_SYM_OBJECT	selects a symmetric block cipher When used in the parameter area of a parent object, this shall be a supported block cipher and not TPM_ALG_NULL
[algorithm]keyBits	TPMU_SYM_KEY_BITS	the key size
[algorithm]mode	TPMU_SYM_MODE	default mode When used in the parameter area of a parent object, this shall be TPM_ALG_CFB.
//[algorithm]details	TPMU_SYM_DETAILS	contains the additional algorithm details, if any NOTE This is commented out at this time as the parser may not produce the proper code for a union if none of the selectors produces any data.

11.1.8 TPM2B_SYM_KEY

This structure is used to hold a symmetric key in the sensitive area of an asymmetric object.

The number of bits in the key is in *keyBits* in the public area. When *keyBits* is not an even multiple of 8 bits, the unused bits of *buffer* will be the most significant bits of *buffer*[0] and *size* will be rounded up to the number of octets required to hold all bits of the key.

NOTE MAX_SYM_KEY_BYTES will be the larger of the largest symmetric key supported by the TPM and the largest digest produced by any hashing algorithm implemented on the TPM.

 Copyright © TCG 2006-2020

Table 142 — Definition of TPM2B_SYM_KEY Structure

Parameter	Type	Description
size	UINT16	size, in octets, of the buffer containing the key; may be zero
buffer [size] {:MAX_SYM_KEY_BYTES}	BYTE	the key

11.1.9 TPMS_SYMCIPHER_PARMS

This structure contains the parameters for a symmetric block cipher object.

Table 143 — Definition of TPMS_SYMCIPHER_PARMS Structure

Parameter	Type	Description
sym	TPMT_SYM_DEF_OBJECT	a symmetric block cipher

11.1.10 TPM2B_LABEL

This buffer holds a *label* or *context* value. For interoperability and backwards compatibility, LABEL_MAX_BUFFER is the minimum of the largest digest on the device and the largest ECC parameter (MAX_ECC_KEY_BYTES) but no more than 32 bytes.

All implementations are required to support at least one hash algorithm that produces a digest of 32 bytes or larger; and any implementation that supports ECC is required to support at least one curve with a key size of 32-bytes or larger.

NOTE Although the maximum size allowed for a *label* or *context* is 32 bytes, the object data structure needs to be sized to allow a 32-byte value.

Table 144 — Definition of TPM2B_LABEL Structure

Parameter	Type	Description
size	UINT16	
buffer[size]{:LABEL_MAX_BUFFER}	BYTE	symmetric data for a created object or the *label* and *context* for a derived object

11.1.11 TPMS_DERIVE

This structure contains the *label* and *context* fields for a derived object. These values are used in the derivation KDF. The values in the *unique* field of *inPublic* area template take precedence over the values in the *inSensitive* parameter.

Table 145 — Definition of TPMS_DERIVE Structure

Parameter	Type	Description
label	TPM2B_LABEL	
context	TPM2B_LABEL	

 Copyright © TCG 2006-2020

11.1.12 TPM2B_DERIVE

Table 146 — Definition of TPM2B_DERIVE Structure

Parameter	Type	Description
size	UINT16	
buffer[size]{: sizeof(TPMS_DERIVE)}	BYTE	symmetric data for a created object or the *label* and *context* for a derived object

11.1.13 TPMU_SENSITIVE_CREATE

This structure allows a TPM2B_SENSITIVE_CREATE structure to carry either a TPM2B_SENSITVE_DATA or a TPM2B_DERIVE structure. The contents of the union are determined by context. When an object is being derived, the derivation values are present.

For interoperability, MAX_SYM_DATA should be 128.

NOTE No marshaling code is automatically generated for this union as it has no selectors that would allow the code to know the context and which member to unmarshal.

Table 147 — Definition of TPMU_SENSITIVE_CREATE Union <>

Parameter	Type	Selector	Description
create[MAX_SYM_DATA]	BYTE		sensitive data for a created symmetric Object
derive	TPMS_DERIVE		*label* and *context* for a derived Object

11.1.14 TPM2B_SENSITIVE_DATA

This buffer wraps the TPMU_SENSITIVE_CREATE structure.

Table 148 — Definition of TPM2B_SENSITIVE_DATA Structure

Parameter	Type	Description
size	UINT16	
buffer[size]{: sizeof(TPMU_SENSITIVE_CREATE)}	BYTE	symmetric data for a created object or the *label* and *context* for a derived object

 Copyright © TCG 2006-2020

11.1.15 TPMS_SENSITIVE_CREATE

This structure defines the values to be placed in the sensitive area of a created object. This structure is only used within a TPM2B_SENSITIVE_CREATE structure.

NOTE When sent to the TPM or unsealed, data is usually encrypted using parameter encryption.

If *data.size* is not zero, and the object is not a *keyedHash*, *data.size* must match the size indicated in the *keySize* of *public.parameters*. If the object is a *keyedHash*, *data.size* may be any value up to the maximum allowed in a TPM2B_SENSITIVE_DATA.

For an asymmetric object, data shall be an Empty Buffer and *sensitiveDataOrigin* shall be SET.

Table 149 — Definition of TPMS_SENSITIVE_CREATE Structure <IN>

Parameter	Type	Description
userAuth	TPM2B_AUTH	the USER auth secret value
data	TPM2B_SENSITIVE_DATA	data to be sealed, a key, or derivation values

11.1.16 TPM2B_SENSITIVE_CREATE

This structure contains the sensitive creation data in a sized buffer. This structure is defined so that both the *userAuth* and *data* values of the TPMS_SENSITIVE_CREATE may be passed as a single parameter for parameter encryption purposes.

Table 150 — Definition of TPM2B_SENSITIVE_CREATE Structure <IN, S>

Parameter	Type	Description
size=	UINT16	size of *sensitive* in octets (may not be zero) NOTE The *userAuth* and data parameters in this buffer may both be zero length but the minimum size of this parameter will be the sum of the size fields of the two parameters of the TPMS_SENSITIVE_CREATE.
sensitive	TPMS_SENSITIVE_CREATE	data to be sealed or a symmetric key value.

11.1.17 TPMS_SCHEME_HASH

This structure is the scheme data for schemes that only require a hash to complete their definition.

Table 151 — Definition of TPMS_SCHEME_HASH Structure

Parameter	Type	Description
hashAlg	TPMI_ALG_HASH	the hash algorithm used to digest the message

 Copyright © TCG 2006-2020

11.1.18 TPMS_SCHEME_ECDAA

This definition is for split signing schemes that require a commit count.

Table 152 — Definition of {ECC} TPMS_SCHEME_ECDAA Structure

Parameter	Type	Description
hashAlg	TPMI_ALG_HASH	the hash algorithm used to digest the message
count	UINT16	the counter value that is used between TPM2_Commit() and the sign operation

11.1.19 TPMI_ALG_KEYEDHASH_SCHEME

This is the list of values that may appear in a *keyedHash* as the *scheme* parameter.

Table 153 — Definition of (TPM_ALG_ID) TPMI_ALG_KEYEDHASH_SCHEME Type

Values	Comments
TPM_ALG_HMAC	the "signing" scheme
TPM_ALG_XOR	the "obfuscation" scheme
+TPM_ALG_NULL	
#TPM_RC_VALUE	

11.1.20 HMAC_SIG_SCHEME

Table 154 — Definition of Types for HMAC_SIG_SCHEME

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_SCHEME_HMAC	

11.1.21 TPMS_SCHEME_XOR

This structure is for the XOR encryption scheme.

NOTE Prior to revision 01.47, the TPM_ALG_NULL hash algorithm was permitted. This produced a zero length key. The TPM_ALG_NULL *hashAlg* now returns TPM_RC_HASH.

Table 155 — Definition of TPMS_SCHEME_XOR Structure

Parameter	Type	Description
hashAlg	TPMI_ALG_HASH	the hash algorithm used to digest the message
kdf	TPMI_ALG_KDF+	the key derivation function

 Copyright © TCG 2006-2020

11.1.22 TPMU_SCHEME_KEYEDHASH

Table 156 — Definition of TPMU_SCHEME_KEYEDHASH Union <IN/OUT >

Parameter	Type	Selector	Description
hmac	TPMS_SCHEME_HMAC	TPM_ALG_HMAC	the "signing" scheme
xor	TPMS_SCHEME_XOR	TPM_ALG_XOR	the "obfuscation" scheme
null		TPM_ALG_NULL	

11.1.23 TPMT_KEYEDHASH_SCHEME

This structure is used for a hash signing object.

Table 157 — Definition of TPMT_KEYEDHASH_SCHEME Structure

Parameter	Type	Description
scheme	+TPMI_ALG_KEYEDHASH_SCHEME	selects the scheme
[scheme]details	TPMU_SCHEME_KEYEDHASH	the scheme parameters

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

11.2 Asymmetric

11.2.1 Signing Schemes

11.2.1.1 Introduction

These structures are used to define the method in which the signature is to be created. These schemes would appear in an object's public area and in commands where the signing scheme is variable.

Every scheme is required to indicate a hash that is used in digesting the message.

11.2.1.2 RSA Signature Schemes

These are the RSA schemes that only need a hash algorithm as a scheme parameter.

For the TPM_ALG_RSAPSS signing scheme, the same hash algorithm is used for digesting TPM-generated data (an attestation structure) and in the KDF used for the masking operation. The salt size is always the largest salt value that will fit into the available space.

Table 158 — Definition of {RSA} Types for RSA Signature Schemes

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_SIG_SCHEME_!ALG.AX	

11.2.1.3 ECC Signature Schemes

Most of the ECC signature schemes only require a hash algorithm to complete the definition and can be typed as TPMS_SCHEME_HASH. Anonymous algorithms also require a count value so they are typed to be TPMS_SCHEME_ECDAA.

Table 159 — Definition of {ECC} Types for ECC Signature Schemes

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_SIG_SCHEME_!ALG.AX	all asymmetric signing schemes
TPMS_SCHEME_ECDAA	TPMS_SIG_SCHEME_!ALG.AXN	schemes that need a hash and a count

 Copyright © TCG 2006-2020

11.2.1.4 TPMU_SIG_SCHEME

This is the union of all of the signature schemes.

NOTE The TPMS_SIG_SCHEME_!ALG is determined by Table 158 or Table 159 and will be either a TPMS_SCHEME_HASH or a TPMS_SCHEME_ECDAA.

Table 160 — Definition of TPMU_SIG_SCHEME Union <IN/OUT >

Parameter	Type	Selector	Description
!ALG.ax	TPMS_SIG_SCHEME_!ALG	TPM_ALG_!ALG	all signing schemes including anonymous schemes
hmac	TPMS_SCHEME_HMAC	TPM_ALG_HMAC	the HMAC scheme
any	TPMS_SCHEME_HASH		selector that allows access to digest for any signing scheme
null		TPM_ALG_NULL	no scheme or default

11.2.1.5 TPMT_SIG_SCHEME

Table 161 — Definition of TPMT_SIG_SCHEME Structure

Parameter	Type	Description
scheme	+TPMI_ALG_SIG_SCHEME	scheme selector
[scheme]details	TPMU_SIG_SCHEME	scheme parameters

11.2.2 Encryption Schemes

11.2.2.1 Introduction

These structures are used to indicate the algorithm used for the encrypting process. These schemes would appear in an object's public area.

NOTE With ECC, the only encryption is with a key exchange of a symmetric key or seed.

11.2.2.2 RSA Encryption Schemes

These are the RSA encryption schemes that only need a hash algorithm as a controlling parameter.

NOTE: These types do not appear in the reference code in the specification but are used in the unmarshaling code.

Table 162 — Definition of Types for {RSA} Encryption Schemes

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_ENC_SCHEME_!ALG.AEH	schemes that only need a hash
TPMS_EMPTY	TPMS_ENC_SCHEME_!ALG.AE	schemes that need nothing

 Copyright © TCG 2006-2020

11.2.2.3 ECC Key Exchange Schemes

These are the ECC schemes that only need a hash algorithm as a controlling parameter.

NOTE: These types do not appear in the reference code in the specification but are used in the unmarshaling code.

Table 163 — Definition of Types for {ECC} ECC Key Exchange

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_KEY_SCHEME_!ALG.AM	schemes that need a hash

11.2.3 Key Derivation Schemes

11.2.3.1 Introduction

These structures are used to define the key derivation for symmetric secret sharing using asymmetric methods. A secret sharing scheme is required in any asymmetric key with the *decrypt* attribute SET.

These schemes would appear in an object's public area and in commands where the secret sharing scheme is variable.

Each scheme includes a symmetric algorithm and a KDF selection.

The qualifying value for each of the KDF schemes is the hash algorithm.

NOTE: These types do not appear in the reference code in the specification but are used in the unmarshaling code.

Table 164 — Definition of Types for KDF Schemes

Type	Name	Description
TPMS_SCHEME_HASH	TPMS_SCHEME_!ALG.HM	hash-based key- or mask-generation functions

11.2.3.2 TPMU_KDF_SCHEME

Table 165 — Definition of TPMU_KDF_SCHEME Union <IN/OUT>

Parameter	Type	Selector	Description
!ALG.HM	TPMS_SCHEME_!ALG.HM	TPM_ALG_!ALG.HM	
null		TPM_ALG_NULL	

11.2.3.3 TPMT_KDF_SCHEME

Table 166 — Definition of TPMT_KDF_SCHEME Structure

Parameter	Type	Description
scheme	+TPMI_ALG_KDF	scheme selector
[scheme]details	TPMU_KDF_SCHEME	scheme parameters

 Copyright © TCG 2006-2020

11.2.3.4 TPMI_ALG_ASYM_SCHEME

List of all of the scheme types for any asymmetric algorithm.

NOTE 1 This is the selector value used to define TPMT_ASYM_SCHEME.

NOTE 2 Most tokens are exclusive in order to filter out SM2 and other multi-protocol algorithm identifiers. The inclusive token “ax” will include those algorithms.

Table 167 — Definition of (TPM_ALG_ID) TPMI_ALG_ASYM_SCHEME Type <IO>

Values	Comments
TPM_ALG_!ALG.am	key exchange methods
TPM_ALG_!ALG.ax	all signing including anonymous
TPM_ALG_!ALG.ae	encrypting schemes
+TPM_ALG_NULL	
#TPM_RC_VALUE	

11.2.3.5 TPMU_ASYM_SCHEME

This union of all asymmetric schemes is used in each of the asymmetric scheme structures. The actual scheme structure is defined by the interface type used for the selector (TPMI_ALG_ASYM_SCHEME).

EXAMPLE The TPMT_RSA_SCHEME structure uses the TPMU_ASYM_SCHEME union but the selector type is TPMI_ALG_RSA_SCHEME. This means that the only elements of the union that can be selected for the TPMT_RSA_SCHEME are those that are in TPMI_RSA_SCHEME.

Table 168 — Definition of TPMU_ASYM_SCHEME Union

Parameter	Type	Selector	Description
!ALG.am	TPMS_KEY_SCHEME_!ALG	TPM_ALG_!ALG	
!ALG.ax	TPMS_SIG_SCHEME_!ALG	TPM_ALG_!ALG	signing and anonymous signing
!ALG.ae	TPMS_ENC_SCHEME_!ALG	TPM_ALG_!ALG	schemes with no hash
anySig	TPMS_SCHEME_HASH		
null		TPM_ALG_NULL	no scheme or default This selects the NULL Signature.

11.2.3.6 TPMT_ASYM_SCHEME

This structure is defined to allow overlay of all of the schemes for any asymmetric object. This structure is not sent on the interface. It is defined so that common functions may operate on any similar scheme structure.

EXAMPLE Since many schemes have a hash algorithm as their defining parameter, a common function can use the digest selector to select the hash of the scheme without a need to cast or use a large switch statement.

11.2.4.5 TPM2B_PUBLIC_KEY_RSA

This sized buffer holds the largest RSA public key supported by the TPM.

NOTE The reference implementation only supports key sizes of 1,024 and 2,048 bits.

Table 174 — Definition of {RSA} TPM2B_PUBLIC_KEY_RSA Structure

Parameter	Type	Description
size	UINT16	size of the buffer The value of zero is only valid for create.
buffer[size] {: MAX_RSA_KEY_BYTES}	BYTE	Value

11.2.4.6 TPMI_RSA_KEY_BITS

This holds the value that is the maximum size allowed for an RSA key.

NOTE 1 An implementation is allowed to provide limited support for smaller RSA key sizes. That is, a TPM may be able to accept a smaller RSA key size in TPM2_LoadExternal() when only the public area is loaded but not accept that smaller key size in any command that loads both the public and private portions of an RSA key. This would allow the TPM to validate signatures using the smaller key but would prevent the TPM from using the smaller key size for any other purpose.

NOTE 2 The definition for RSA_KEY_SIZES_BITS used in the reference implementation is found in TPM 2.0 Part 4, Implementation.h

Table 175 — Definition of {RSA} (TPM_KEY_BITS) TPMI_RSA_KEY_BITS Type

Parameter	Description
$RSA_KEY_SIZES_BITS	the number of bits in the supported key
#TPM_RC_VALUE	error when key size is not supported

11.2.4.7 TPM2B_PRIVATE_KEY_RSA

This sized buffer holds the largest RSA prime number supported by the TPM.

NOTE 1 All primes are required to have exactly half the number of significant bits as the public modulus, and the square of each prime is required to have the same number of significant bits as the public modulus.

NOTE 2 RSA_PRIVATE_SIZE is a vendor specific value that can be (MAX_RSA_KEY_BYTES / 2) or ((MAX_RSA_KEY_BYTES * 5) ./ 2. The larger size would only apply to keys that have *fixedTPM* parents. The larger size was added in revision 01.53.

Table 176 — Definition of {RSA} TPM2B_PRIVATE_KEY_RSA Structure

Parameter	Type	Description
size	UINT16	
buffer[size]{:RSA_PRIVATE_SIZE }	BYTE

11.2.5 ECC

11.2.5.1 TPM2B_ECC_PARAMETER

This sized buffer holds the largest ECC parameter (coordinate) supported by the TPM.

Table 177 — Definition of TPM2B_ECC_PARAMETER Structure

Parameter	Type	Description
size	UINT16	size of *buffer*
buffer[size] {:MAX_ECC_KEY_BYTES}	BYTE	the parameter data

11.2.5.2 TPMS_ECC_POINT

This structure holds two ECC coordinates that, together, make up an ECC point.

Table 178 — Definition of {ECC} TPMS_ECC_POINT Structure

Parameter	Type	Description
x	TPM2B_ECC_PARAMETER	X coordinate
y	TPM2B_ECC_PARAMETER	Y coordinate

11.2.5.3 TPM2B_ECC_POINT

This structure is defined to allow a point to be a single sized parameter so that it may be encrypted.

NOTE If the point is to be omitted, the X and Y coordinates need to be individually set to Empty Buffers. The minimum value for size will be four. It is checked indirectly by unmarshaling of the TPMS_ECC_POINT. If the type of *point* were BYTE, then *size* could have been zero. However, this would complicate the process of marshaling the structure.

Table 179 — Definition of {ECC} TPM2B_ECC_POINT Structure

Parameter	Type	Description
size=	UINT16	size of the remainder of this structure
point	TPMS_ECC_POINT	coordinates
#TPM_RC_SIZE		error returned if the unmarshaled size of *point* is not exactly equal to *size*

11.2.5.7 TPMS_ALGORITHM_DETAIL_ECC

This structure is used to report on the curve parameters of an ECC curve. It is returned by TPM2_ECC_Parameters().

Table 183 — Definition of {ECC} TPMS_ALGORITHM_DETAIL_ECC Structure <OUT>

Parameter	Type	Description
curveID	TPM_ECC_CURVE	identifier for the curve
keySize	UINT16	Size in bits of the key
kdf	TPMT_KDF_SCHEME+	if not TPM_ALG_NULL, the required KDF and hash algorithm used in secret sharing operations
sign	TPMT_ECC_SCHEME+	If not TPM_ALG_NULL, this is the mandatory signature scheme that is required to be used with this curve.
p	TPM2B_ECC_PARAMETER	Fp (the modulus)
a	TPM2B_ECC_PARAMETER	coefficient of the linear term in the curve equation
b	TPM2B_ECC_PARAMETER	constant term for curve equation
gX	TPM2B_ECC_PARAMETER	x coordinate of base point G
gY	TPM2B_ECC_PARAMETER	y coordinate of base point G
n	TPM2B_ECC_PARAMETER	order of G
h	TPM2B_ECC_PARAMETER	cofactor (a size of zero indicates a cofactor of 1)

11.3 Signatures

11.3.1 TPMS_SIGNATURE_RSA

Table 184 — Definition of {RSA} TPMS_SIGNATURE_RSA Structure

Parameter	Type	Description
hash	TPMI_ALG_HASH	the hash algorithm used to digest the message TPM_ALG_NULL is not allowed.
sig	TPM2B_PUBLIC_KEY_RSA	The signature is the size of a public key.

signatureR	TPM2B_ECC_PARAMETER	
signatureS	TPM2B_ECC_PARAMETER	

Table 187 — Definition of Types for {ECC} TPMS_SIGNATURE_ECC

Type	Name	Description
TPMS_SIGNATURE_ECC	TPMS_SIGNATURE_!ALG.ax	

11.3.3 TPMU_SIGNATURE

A TPMU_SIGNATURE_COMPOSITE is a union of the various signatures that are supported by a particular TPM implementation. The union allows substitution of any signature algorithm wherever a signature is required in a structure.

NOTE All TPM are required to support a hash algorithm and the HMAC algorithm.

When a symmetric algorithm is used for signing, the signing algorithm is assumed to be an HMAC based on the indicated hash algorithm. The HMAC key will either be referenced as part of the usage or will be implied by context.

Table 188 — Definition of TPMU_SIGNATURE Union <IN/OUT>

Parameter	Type	Selector	Description
!ALG.ax	TPMS_SIGNATURE_!ALG.ax	TPM_ALG_!ALG.ax	all asymmetric signatures
hmac	TPMT_HA	TPM_ALG_HMAC	HMAC signature (required to be supported)
any	TPMS_SCHEME_HASH		used to access the hash
null		TPM_ALG_NULL	the NULL signature

11.3.4 TPMT_SIGNATURE

Table 189 shows the basic algorithm-agile structure when a symmetric or asymmetric signature is indicated. The *sigAlg* parameter indicates the algorithm used for the signature. This structure is output from commands such as the attestation commands and TPM2_Sign, and is an input to commands such as TPM2_VerifySignature(), TPM2_PolicySigned(), and TPM2_FieldUpgradeStart().

Table 189 — Definition of TPMT_SIGNATURE Structure

Parameter	Type	Description
sigAlg	+TPMI_ALG_SIG_SCHEME	selector of the algorithm used to construct the signature
[sigAlg]signature	TPMU_SIGNATURE	This shall be the actual signature information.

11.4 Key/Secret Exchange

11.4.1 Introduction

The structures in 11.4 are used when a key or secret is being exchanged. The exchange may be in

- TPM2_StartAuthSession() where the secret is injected for salting the session,
- TPM2_Duplicate(), TPM2_Import, or TPM2_Rewrap() where the secret is the symmetric encryption key for the outer wrapper of a duplication blob, or
- TPM2_ActivateIdentity() or TPM2_CreateIdentity() where the secret is the symmetric encryption key for the credential blob.

Particulars are described in TPM 2.0 Part 1.

11.4.2 TPMU_ENCRYPTED_SECRET

This structure is used to hold either an ephemeral public point for ECDH, an OAEP-encrypted block for RSA, or a symmetrically encrypted value. This structure is defined for the limited purpose of determining the size of a TPM2B_ENCRYPTED_SECRET.

The symmetrically encrypted value may use either CFB or XOR encryption.

NOTE Table 190 is illustrative. It would be modified depending on the algorithms supported in the TPM.

Table 190 — Definition of TPMU_ENCRYPTED_SECRET Union

Parameter	Type	Selector	Description
ecc[sizeof(TPMS_ECC_POINT)]	BYTE	TPM_ALG_ECC	
rsa[MAX_RSA_KEY_BYTES]	BYTE	TPM_ALG_RSA	
symmetric[sizeof(TPM2B_DIGEST)]	BYTE	TPM_ALG_SYMCIPHER	
keyedHash[sizeof(TPM2B_DIGEST)]	BYTE	TPM_ALG_KEYEDHASH	Any symmetrically encrypted secret value will be limited to be no larger than a digest.

11.4.3 TPM2B_ENCRYPTED_SECRET

Table 191 — Definition of TPM2B_ENCRYPTED_SECRET Structure

12 Key/Object Complex

12.1 Introduction

An object description requires a TPM2B_PUBLIC structure and may require a TPMT_SENSITIVE structure. When the structure is stored off the TPM, the TPMT_SENSITIVE structure is encrypted within a TPM2B_PRIVATE structure.

When the object requires two components for its description, those components are loaded as separate parameters in the TPM2_Load() command. When the TPM creates an object that requires both components, the TPM will return them as separate parameters from the TPM2_Create() operation.

The TPM may produce multiple different TPM2B_PRIVATE structures for a single TPM2B_PUBLIC structure. Creation of a modified TPM2B_PRIVATE structure requires that the full structure be loaded with the TPM2_Load() command, modification of the TPMT_SENSITIVE data, and output of a new TPM2B_PRIVATE structure.

12.2 Public Area Structures

12.2.1 Description

Clause 12.2 defines the TPM2B_PUBLIC structure and the higher-level substructure that may be contained in a TPM2B_PUBLIC. The higher-level structures that are currently defined for inclusion in a TPM2B_PUBLIC are the

- structures for asymmetric keys,
- structures for symmetric keys, and
- structures for sealed data.

12.2.2 TPMI_ALG_PUBLIC

Table 192 — Definition of (TPM_ALG_ID) TPMI_ALG_PUBLIC Type

Values	Comments
TPM_ALG_!ALG.o	All object types
#TPM_RC_TYPE	response code when a public type is not supported

 Copyright © TCG 2006-2020

12.2.3 Type-Specific Parameters

12.2.3.1 Description

The public area contains two fields (*parameters* and *unique*) that vary by object type. The *parameters* field varies according to the *type* of the object but the contents may be the same across multiple instances of a particular *type*. The unique field format also varies according to the type of the object and will also be unique for each instance.

For a symmetric key (*type* == TPM_ALG_SYMCIPHER), HMAC key (*type* == TPM_ALG_KEYEDHASH) or data object (also, *type* == TPM_ALG_KEYEDHASH), the contents of *unique* shall be computed from components of the sensitive area of the object as follows:

$$unique \coloneqq \mathbf{H}_{nameAlg}(seedValue \mid\mid sensitive) \quad (9)$$

where

$\mathbf{H}_{nameAlg}()$	the hash algorithm used to compute the Name of the object
$seedValue$	the digest-sized obfuscation value in the sensitive area of a symmetric key or symmetric data object found in a TPMT_SENSITIVE.*seedValue.buffer*
$sensitive$	the secret key/data of the object in the TPMT_SENSITIVE.*sensitive.any.buffer*

12.2.3.2 TPMU_PUBLIC_ID

This is the union of all values allowed in in the *unique* field of a TPMT_PUBLIC.

NOTE The derive member cannot be unmarshaled in a TPMU_PUBLIC_ID. It is placed in this structure so that the maximum size of a TPM2B_TEMPLATE will be computed correctly.

Table 193 — Definition of TPMU_PUBLIC_ID Union <IN/OUT>

Parameter	Type	Selector	Description
keyedHash	TPM2B_DIGEST	TPM_ALG_KEYEDHASH	
sym	TPM2B_DIGEST	TPM_ALG_SYMCIPHER	
rsa	TPM2B_PUBLIC_KEY_RSA	TPM_ALG_RSA	
ecc	TPMS_ECC_POINT	TPM_ALG_ECC	
derive	TPMS_DERIVE		only allowed for TPM2_CreateLoaded when *parentHandle* is a Derivation Parent.

 Copyright © TCG 2006-2020

12.2.3.3 TPMS_KEYEDHASH_PARMS

This structure describes the parameters that would appear in the public area of a KEYEDHASH object.

NOTE Although the names are the same, the types of the structures are not the same as for asymmetric parameter lists.

Table 194 — Definition of TPMS_KEYEDHASH_PARMS Structure

Parameter	Type	Description
scheme	TPMT_KEYEDHASH_SCHEME+	Indicates the signing method used for a *keyedHash* signing object. This field also determines the size of the data field for a data object created with TPM2_Create() or TPM2_CreatePrimary().

12.2.3.4 TPMS_ASYM_PARMS

This structure contains the common public area parameters for an asymmetric key. The first two parameters of the parameter definition structures of an asymmetric key shall have the same two first components.

NOTE The sign parameter may have a different type in order to allow different schemes to be selected for each asymmetric type but the first parameter of each scheme definition shall be a TPM_ALG_ID for a valid signing scheme.

Table 195 — Definition of TPMS_ASYM_PARMS Structure <>

Parameter	Type	Description
symmetric	TPMT_SYM_DEF_OBJECT+	the companion symmetric algorithm for a restricted decryption key and shall be set to a supported symmetric algorithm This field is optional for keys that are not decryption keys and shall be set to TPM_ALG_NULL if not used.
scheme	TPMT_ASYM_SCHEME+	for a key with the *sign* attribute SET, a valid signing scheme for the key type for a key with the *decrypt* attribute SET, a valid key exchange protocol for a key with sign and decrypt attributes, shall be TPM_ALG_NULL

 Copyright © TCG 2006-2020

12.2.3.5 TPMS_RSA_PARMS

A TPM compatible with this specification and supporting RSA shall support two primes and an *exponent* of zero. An exponent of zero indicates that the exponent is the default of $2^{16} + 1$. Support for other values is optional. Use of other exponents in duplicated keys is not recommended because the resulting keys would not be interoperable with other TPMs.

NOTE Implementations are not required to check that *exponent* is the default exponent. They may fail to load the key if *exponent* is not zero. The reference implementation allows the values listed in the table.

Table 196 — Definition of {RSA} TPMS_RSA_PARMS Structure

Parameter	Type	Description
symmetric	TPMT_SYM_DEF_OBJECT+	for a restricted decryption key, shall be set to a supported symmetric algorithm, key size, and mode. if the key is not a restricted decryption key, this field shall be set to TPM_ALG_NULL.
scheme	TPMT_RSA_SCHEME+	scheme.scheme shall be: for an unrestricted signing key, either TPM_ALG_RSAPSS TPM_ALG_RSASSA or TPM_ALG_NULL for a restricted signing key, either TPM_ALG_RSAPSS or TPM_ALG_RSASSA for an unrestricted decryption key, TPM_ALG_RSAES, TPM_ALG_OAEP, or TPM_ALG_NULL unless the object also has the *sign* attribute for a restricted decryption key, TPM_ALG_NULL NOTE When both sign and decrypt are SET, restricted shall be CLEAR and scheme shall be TPM_ALG_NULL.
keyBits	TPMI_RSA_KEY_BITS	number of bits in the public modulus
exponent	UINT32	the public exponent A prime number greater than 2.

 Copyright © TCG 2006-2020

12.2.3.6 TPMS_ECC_PARMS

This structure contains the parameters for prime modulus ECC.

Table 197 — Definition of {ECC} TPMS_ECC_PARMS Structure

Parameter	Type	Description
symmetric	TPMT_SYM_DEF_OBJECT+	for a restricted decryption key, shall be set to a supported symmetric algorithm, key size. and mode. if the key is not a restricted decryption key, this field shall be set to TPM_ALG_NULL.
scheme	TPMT_ECC_SCHEME+	If the *sign* attribute of the key is SET, then this shall be a valid signing scheme. NOTE If the *sign* parameter in *curveID* indicates a mandatory scheme, then this field shall have the same value. If the *decrypt* attribute of the key is SET, then this shall be a valid key exchange scheme or TPM_ALG_NULL. If the key is a Storage Key, then this field shall be TPM_ALG_NULL.
curveID	TPMI_ECC_CURVE	ECC curve ID
kdf	TPMT_KDF_SCHEME+	an optional key derivation scheme for generating a symmetric key from a Z value If the *kdf* parameter associated with *curveID* is not TPM_ALG_NULL then this is required to be NULL. NOTE There are currently no commands where this parameter has effect and, in the reference code, this field needs to be set to TPM_ALG_NULL.

12.2.3.7 TPMU_PUBLIC_PARMS

Table 198 defines the possible parameter definition structures that may be contained in the public portion of a key. If the Object can be a parent, the first field must be a TPMT_SYM_DEF_OBJECT. See 11.1.7.

Table 198 — Definition of TPMU_PUBLIC_PARMS Union <IN/OUT>

Parameter	Type	Selector	Description(1)
keyedHashDetail	TPMS_KEYEDHASH_PARMS	TPM_ALG_KEYEDHASH	sign | decrypt | neither(2)
symDetail	TPMS_SYMCIPHER_PARMS	TPM_ALG_SYMCIPHER	sign | decrypt | neither(2)
rsaDetail	TPMS_RSA_PARMS	TPM_ALG_RSA	decrypt + sign(2)
eccDetail	TPMS_ECC_PARMS	TPM_ALG_ECC	decrypt + sign(2)
asymDetail	TPMS_ASYM_PARMS		common scheme structure for RSA and ECC keys
NOTES 1) Description column indicates which of TPMA_OBJECT.*decrypt* or TPMA_OBJECT.*sign* may be set. 2) "+" indicates that both may be set but one shall be set. "|" indicates the optional settings.			

 Copyright © TCG 2006-2020

12.2.3.8 TPMT_PUBLIC_PARMS

This structure is used in TPM2_TestParms() to validate that a set of algorithm parameters is supported by the TPM.

Table 199 — Definition of TPMT_PUBLIC_PARMS Structure

Parameter	Type	Description
type	TPMI_ALG_PUBLIC	the algorithm to be tested
[type]parameters	TPMU_PUBLIC_PARMS	the algorithm details

12.2.4 TPMT_PUBLIC

Table 200 defines the public area structure. The Name of the object is *nameAlg* concatenated with the digest of this structure using *nameAlg*.

Table 200 — Definition of TPMT_PUBLIC Structure

Parameter	Type	Description
type	TPMI_ALG_PUBLIC	"algorithm" associated with this object
nameAlg	+TPMI_ALG_HASH	algorithm used for computing the Name of the object NOTE The "+" indicates that the instance of a TPMT_PUBLIC may have a "+" to indicate that the *nameAlg* may be TPM_ALG_NULL.
objectAttributes	TPMA_OBJECT	attributes that, along with *type*, determine the manipulations of this object
authPolicy	TPM2B_DIGEST	optional policy for using this key The policy is computed using the *nameAlg* of the object. NOTE Shall be the Empty Policy if no authorization policy is present.
[type]parameters	TPMU_PUBLIC_PARMS	the algorithm or structure details
[type]unique	TPMU_PUBLIC_ID	the unique identifier of the structure For an asymmetric key, this would be the public key.

12.2.5 TPM2B_PUBLIC

This sized buffer is used to embed a TPMT_PUBLIC in a load command and in any response that returns a public area.

Table 201 — Definition of TPM2B_PUBLIC Structure

Parameter	Type	Description
size=	UINT16	size of publicArea NOTE The "=" will force the TPM to try to unmarshal a TPMT_PUBLIC and check that the unmarshaled size matches the value of *size*. If all the required fields of a TPMT_PUBLIC are not present, the TPM will return an error (generally TPM_RC_SIZE) when attempting to unmarshal the TPMT_PUBLIC.
publicArea	+TPMT_PUBLIC	the public area NOTE The "+" indicates that the caller may specify that use of TPM_ALG_NULL is allowed for *nameAlg.*

 Copyright © TCG 2006-2020

12.2.6 TPM2B_TEMPLATE

This sized buffer is used to embed a TPMT_TEMPLATE for TPM2_CreateLoaded().

Unmarshaling of this structure is fairly complex due to requirements for backwards compatibility. Unlike a TPM2B_PUBLIC, this structure is unmarshaled as an array of bytes that is passed to the action code. The action code will then unmarshal the embedded structure.

If the parent is not a derivation parent, this structure is unmarshaled normally. If the parent is a derivation parent, *unique* is unmarshaled as a TPMS_DERIVE structure (*label* and *context*). See 12.2.3.2.

Table 202 — Definition of TPM2B_TEMPLATE Structure

Parameter	Type	Description
size	UINT16	size of publicArea
buffer[size]{:sizeof(TPMT_PUBLIC)}	BYTE	the public area

12.3 Private Area Structures

12.3.1 Introduction

The structures in 12.2.6 define the contents and construction of the private portion of a TPM object. A TPM2B_PRIVATE along with a TPM2B_PUBLIC are needed to describe a TPM object.

A TPM2B_PRIVATE area may be encrypted by different symmetric algorithms or, in some cases, not encrypted at all.

12.3.2 Sensitive Data Structures

12.3.2.1 Introduction

The structures in 12.3.2 define the presumptive internal representations of the sensitive areas of the various entities. A TPM may store the sensitive information in any desired format but when constructing a TPM_PRIVATE, the formats in 12.3.2 shall be used.

12.3.2.2 TPM2B_PRIVATE_VENDOR_SPECIFIC

This structure is defined for coding purposes. For IO to the TPM, the sensitive portion of the key will be in a canonical form. For an RSA key, this will be one of the prime factors of the public modulus. After loading, it is typical that other values will be computed so that computations using the private key will not need to start with just one prime factor. This structure can be used to store the results of such vendor-specific calculations.

The value for PRIVATE_VENDOR_SPECIFIC_BYTES is determined by the vendor.

Table 203 — Definition of TPM2B_PRIVATE_VENDOR_SPECIFIC Structure

Parameter	Type	Description
size	UINT16	
buffer[size]{:PRIVATE_VENDOR_SPECIFIC_BYTES}	BYTE	

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

12.3.2.3 TPMU_SENSITIVE_COMPOSITE

Table 204 — Definition of TPMU_SENSITIVE_COMPOSITE Union <IN/OUT>

Parameter	Type	Selector	Description
rsa	TPM2B_PRIVATE_KEY_RSA	TPM_ALG_RSA	a prime factor of the public key
ecc	TPM2B_ECC_PARAMETER	TPM_ALG_ECC	the integer private key
bits	TPM2B_SENSITIVE_DATA	TPM_ALG_KEYEDHASH	the private data
sym	TPM2B_SYM_KEY	TPM_ALG_SYMCIPHER	the symmetric key
any	TPM2B_PRIVATE_VENDOR_SPECIFIC		vendor-specific size for key storage

12.3.2.4 TPMT_SENSITIVE

authValue shall not be larger than the size of the digest produced by the *nameAlg* of the object. *seedValue* shall be the size of the digest produced by the *nameAlg* of the object.

Table 205 — Definition of TPMT_SENSITIVE Structure

Parameter	Type	Description
sensitiveType	TPMI_ALG_PUBLIC	identifier for the sensitive area This shall be the same as the *type* parameter of the associated public area.
authValue	TPM2B_AUTH	user authorization data The authValue may be a zero-length string.
seedValue	TPM2B_DIGEST	for a parent object, the optional protection seed; for other objects, the obfuscation value
[sensitiveType]sensitive	TPMU_SENSITIVE_COMPOSITE	the type-specific private data

12.3.3 TPM2B_SENSITIVE

The TPM2B_SENSITIVE structure is used as a parameter in TPM2_LoadExternal(). It is an unencrypted sensitive area but it may be encrypted using parameter encryption.

NOTE 1 When this structure is unmarshaled, the *sensitiveType* determines what type of value is unmarshaled. Each value of *sensitiveType* is associated with a TPM2B. It is the maximum size for each of the TPM2B values that will determine if the unmarshal operation is successful. Since there is no selector for the *any* or *vendor* options for the union, the maximum input and output sizes for a TPM2B_SENSITIVE are not affected by the sizes of those parameters.

NOTE 2 The unmarshaling function validates that *size* equals the size of the value that is unmarshaled.

Table 206 — Definition of TPM2B_SENSITIVE Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	size of the *private* structure
sensitiveArea	TPMT_SENSITIVE	an unencrypted sensitive area

 Copyright © TCG 2006-2020

12.3.4 Encryption

A TPMS_SENSITIVE is the input to the encryption process. All TPMS_ENCRYPT structures are CFB-encrypted using a key and Initialization Vector (IV) that are derived from a seed value.

The method of generating the key and IV is described in "Protected Storage" subclause "Symmetric Encryption." in TPM 2.0 Part 1.

12.3.5 Integrity

The integrity computation is used to ensure that a protected object is not modified when stored in memory outside of the TPM.

The method of protecting the integrity of the sensitive area is described in "Protected Storage" subclause "Integrity" in TPM 2.0 Part 1.

12.3.6 _PRIVATE

This structure is defined to size the contents of a TPM2B_PRIVATE. This structure is not directly marshaled or unmarshaled.

For TPM2_Duplicate() and TPM2_Import(), the TPM2B_PRIVATE may contain multiply encrypted data and two integrity values. In some cases, the sensitive data is not encrypted and the integrity value is not present.

For TPM2_Load() and TPM2_Create(), *integrityInner* is always present.

If *integrityInner* is present, it and *sensitive* are encrypted as a single block.

When an integrity value is not needed, it is not present and it is not represented by an Empty Buffer.

Table 207 — Definition of _PRIVATE Structure <>

Parameter	Type	Description
integrityOuter	TPM2B_DIGEST	
integrityInner	TPM2B_DIGEST	could also be a TPM2B_IV
sensitive	TPM2B_SENSITIVE	the sensitive area

12.3.7 TPM2B_PRIVATE

The TPM2B_PRIVATE structure is used as a parameter in multiple commands that create, load, and modify the sensitive area of an object.

When the TPM returns a TPM2B_PRIVATE structure, the TPM pads the TPM2B_AUTH to its maximum size.

Table 208 — Definition of TPM2B_PRIVATE Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	size of the *private* structure
buffer[size] {:sizeof(_PRIVATE)}	BYTE	an encrypted private area

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

12.4 Identity Object

12.4.1 Description

An identity object is used to convey credential protection value (CV) to a TPM that can load the object associated with the object. The CV is encrypted to a storage key on the target TPM, and if the credential integrity checks and the proper object is loaded in the TPM, then the TPM will return the CV.

12.4.2 TPMS_ID_OBJECT

This structure is used for sizing the TPM2B_ID_OBJECT.

Table 209 — Definition of TPMS_ID_OBJECT Structure <>

Parameter	Type	Description
integrityHMAC	TPM2B_DIGEST	HMAC using the nameAlg of the storage key on the target TPM
encIdentity	TPM2B_DIGEST	credential protector information returned if name matches the referenced object All of the *encIdentity* is encrypted, including the size field. NOTE The TPM is not required to check that the size is not larger than the digest of the *nameAlg*. However, if the size is larger, the ID object may not be usable on a TPM that has no digest larger than produced by *nameAlg*.

12.4.3 TPM2B_ID_OBJECT

This structure is an output from TPM2_MakeCredential() and is an input to TPM2_ActivateCredential().

Table 210 — Definition of TPM2B_ID_OBJECT Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	size of the *credential* structure
credential[size]{:sizeof(TPMS_ID_OBJECT)}	BYTE	an encrypted credential area

 Copyright © TCG 2006-2020

13 NV Storage Structures

13.1 TPM_NV_INDEX

A TPM_NV_INDEX is used to reference a defined location in NV memory. The format of the Index is changed from TPM 1.2 in order to include the Index in the reserved handle space. Handles in this range use the digest of the public area of the Index as the Name of the entity in authorization computations

The 32-bit TPM 1.2 NV Index format is shown in Figure 4. In order to allow the Index to fit into the 24 bits available in the reserved handle space, the Index value format is changed as shown in Figure 5.

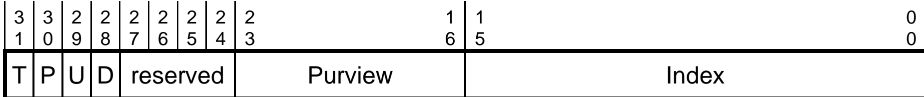

Figure 4 — TPM 1.2 TPM_NV_INDEX

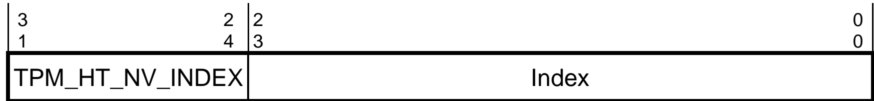

Figure 5 — TPM 2.0 TPM_NV_INDEX

NOTE This TPM_NV_INDEX format does not retain the Purview field and the D bit is not a part of an Index handle as in TPM 1.2. The TPMA_NV_PLATFORMCREATE attribute is a property of an Index that provides functionality similar to the D bit.

A valid Index handle will have an MSO of TPM_HT_NV_INDEX.

NOTE This structure is not used. It is defined here to indicate how the fields of the handle are assigned. The exemplary unmarshaling code unmarshals a TPM_HANDLE and validates that it is in the range for a TPM_NV_INDEX.

Table 211 — Definition of (UINT32) TPM_NV_INDEX Bits <>

Bit	Name	Definition
23:00	index	The Index of the NV location
31:24	RH_NV	constant value of TPM_HT_NV_INDEX indicating the NV Index range

 Copyright © TCG 2006-2020

Some prior versions of this specification contained a table here (Options for space Field of TPM_NV_INDEX) that assigned subsets of the index field to different entities. Since this assignment was a convention and not an architectural element of the TPM, the table was removed and the information is now contained in a registry document that is maintained by the TCG.

13.2 TPM_NT

This table lists the values of the TPM_NT field of a TPMA_NV. See Table 214 for usage.

Table 212 — Definition of TPM_NT Constants

Name	Value	Description
TPM_NT_ORDINARY	0x0	Ordinary – contains data that is opaque to the TPM that can only be modified using TPM2_NV_Write().
TPM_NT_COUNTER	0x1	Counter – contains an 8-octet value that is to be used as a counter and can only be modified with TPM2_NV_Increment()
TPM_NT_BITS	0x2	Bit Field – contains an 8-octet value to be used as a bit field and can only be modified with TPM2_NV_SetBits().
TPM_NT_EXTEND	0x4	Extend – contains a digest-sized value used like a PCR. The Index can only be modified using TPM2_NV_Extend(). The extend will use the nameAlg of the Index.
TPM_NT_PIN_FAIL	0x8	PIN Fail - contains *pinCount* that increments on a PIN authorization failure and a *pinLimit*
TPM_NT_PIN_PASS	0x9	PIN Pass - contains *pinCount* that increments on a PIN authorization success and a *pinLimit*

All other TPM_NT values are reserved and TPM2_NV_DefineSpace() returns TPM_RC_ATTRIBUTES.

NOTE 1 These values are compatible with previous versions of this specification, which used a bit map for this field.

NOTE 2 This field described by Table 212 is 4 bits.

13.3 TPMS_NV_PIN_COUNTER_PARAMETERS

This is the data that can be written to and read from a TPM_NT_PIN_PASS or TPM_NT_PIN_FAIL non-volatile index. *pinCount* is the most significant octets. *pinLimit* is the least significant octets.

Table 213 — Definition of TPMS_NV_PIN_COUNTER_PARAMETERS Structure

Parameter	Type	Description
pinCount	UINT32	This counter shows the current number of successful authValue authorization attempts to access a TPM_NT_PIN_PASS index or the current number of unsuccessful authValue authorization attempts to access a TPM_NT_PIN_FAIL index.
pinLimit	UINT32	This threshold is the value of *pinCount* at which the authValue authorization of the host TPM_NT_PIN_PASS or TPM_NT_PIN_FAIL index is locked out.

13.4 TPMA_NV (NV Index Attributes)

This structure allows the TPM to keep track of the data and permissions to manipulate an NV Index.

 Copyright © TCG 2006-2020

The platform controls (TPMA_NV_PPWRITE and TPMA_NV_PPREAD) and owner controls (TPMA_NV_OWNERWRITE and TPMA_NV_OWNERREAD) give the platform and owner access to NV Indexes using Platform Authorization or Owner Authorization rather than the *authValue* or *authPolicy* of the Index.

If access to an NV Index is to be restricted based on PCR, then an appropriate *authPolicy* shall be provided.

NOTE *platformAuth* or *ownerAuth* can be provided in any type of authorization session or as a password.

If TPMA_NV_AUTHREAD is SET, then the Index may be read if the Index *authValue* is provided. If TPMA_NV_POLICYREAD is SET, then the Index may be read if the Index *authPolicy* is satisfied.

At least one of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD shall be SET.

If TPMA_NV_AUTHWRITE is SET, then the Index may be written if the Index *authValue* is provided. If TPMA_NV_POLICYWRITE is SET, then the Index may be written if the Index *authPolicy* is satisfied.

At least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE shall be SET.

If TPMA_NV_WRITELOCKED is SET, then the Index may not be written. If TPMA_NV_WRITEDEFINE is SET, TPMA_NV_WRITELOCKED may not be CLEAR except by deleting and redefining the Index. If TPMA_NV_WRITEDEFINE is CLEAR, then TPMA_NV_WRITELOCKED will be CLEAR on the next TPM2_Startup(TPM_SU_CLEAR).

NOTE If TPMA_NV_WRITELOCKED is SET, but TPMA_NV_WRITTEN is CLEAR, then TPMA_NV_WRITELOCKED is CLEAR by TPM Reset or TPM Restart. This action occurs even if the TPMA_NV_WRITEDEFINE attribute is SET. This action prevents an NV Index from being defined that can never be written, and permits a use case where an Index is defined, but the user wants to prohibit writes until after a reboot.

If TPMA_NV_READLOCKED is SET, then the Index may not be read. TPMA_NV_READLOCKED will be CLEAR on the next TPM2_Startup(TPM_SU_CLEAR).

NOTE The TPM is expected to maintain indicators to indicate that the Index is temporarily locked. The state of these indicators is reported in the TPMA_NV_READLOCKED and TPMA_NV_WRITELOCKED attributes.

If the TPM_NT is TPM_NT_EXTEND, then writes to the Index will cause an update of the Index using the extend operation with the *nameAlg* used to create the digest.

If TPM_NT is TPM_NT_PIN_FAIL, TPMA_NV_NO_DA must be SET. This removes ambiguity over which Dictionary Attack defense protects a TPM_NV_PIN_FAIL's *authValue*.

When the Index is created (TPM2_NV_DefineSpace()), TPMA_NV_WRITELOCKED, TPMA_NV_READLOCKED, and TPMA_NV_WRITTEN shall all be CLEAR in the parameter that defines the attributes of the created Index.

Level 00 Revision 01.59 **Copyright © TCG 2006-2020** November 8, 2019

Table 214 — Definition of (UINT32) TPMA_NV Bits

Bit	Name	Description
0	TPMA_NV_PPWRITE	**SET (1):** The Index data can be written if Platform Authorization is provided. **CLEAR (0):** Writing of the Index data cannot be authorized with Platform Authorization.
1	TPMA_NV_OWNERWRITE	**SET (1):** The Index data can be written if Owner Authorization is provided. **CLEAR (0):** Writing of the Index data cannot be authorized with Owner Authorization.
2	TPMA_NV_AUTHWRITE	**SET (1):** Authorizations to change the Index contents that require USER role may be provided with an HMAC session or password. **CLEAR (0):** Authorizations to change the Index contents that require USER role may not be provided with an HMAC session or password.
3	TPMA_NV_POLICYWRITE	**SET (1):** Authorizations to change the Index contents that require USER role may be provided with a policy session. **CLEAR (0):** Authorizations to change the Index contents that require USER role may not be provided with a policy session. NOTE TPM2_NV_ChangeAuth() always requires that authorization be provided in a policy session.
7:4	TPM_NT	The type of the index. NOTE A TPM is not required to support all TPM_NT values
9:8	Reserved	shall be zero reserved for future use
10	TPMA_NV_POLICY_DELETE	**SET (1):** Index may not be deleted unless the *authPolicy* is satisfied using TPM2_NV_UndefineSpaceSpecial(). **CLEAR (0):** Index may be deleted with proper platform or owner authorization using TPM2_NV_UndefineSpace(). NOTE An Index with this attribute and a policy that cannot be satisfied (e.g., an Empty Policy) cannot be deleted.
11	TPMA_NV_WRITELOCKED	**SET (1):** Index cannot be written. **CLEAR (0):** Index can be written.
12	TPMA_NV_WRITEALL	**SET (1):** A partial write of the Index data is not allowed. The write size shall match the defined space size. **CLEAR (0):** Partial writes are allowed. This setting is required if the .*dataSize* of the Index is larger than NV_MAX_BUFFER_SIZE for the implementation.
13	TPMA_NV_WRITEDEFINE	**SET (1):** TPM2_NV_WriteLock() may be used to prevent further writes to this location. **CLEAR (0):** TPM2_NV_WriteLock() does not block subsequent writes if TPMA_NV_WRITE_STCLEAR is also CLEAR.
14	TPMA_NV_WRITE_STCLEAR	**SET (1):** TPM2_NV_WriteLock() may be used to prevent further writes to this location until the next TPM Reset or TPM Restart. **CLEAR (0):** TPM2_NV_WriteLock() does not block subsequent writes if TPMA_NV_WRITEDEFINE is also CLEAR.
15	TPMA_NV_GLOBALLOCK	**SET (1):** If TPM2_NV_GlobalWriteLock() is successful, TPMA_NV_WRITELOCKED is set. **CLEAR (0):** TPM2_NV_GlobalWriteLock() has no effect on the writing of the data at this Index.

 Copyright © TCG 2006-2020

Bit	Name	Description
16	TPMA_NV_PPREAD	**SET (1):** The Index data can be read if Platform Authorization is provided. **CLEAR (0):** Reading of the Index data cannot be authorized with Platform Authorization.
17	TPMA_NV_OWNERREAD	**SET (1):** The Index data can be read if Owner Authorization is provided. **CLEAR (0):** Reading of the Index data cannot be authorized with Owner Authorization.
18	TPMA_NV_AUTHREAD	**SET (1):** The Index data may be read if the *authValue* is provided. **CLEAR (0):** Reading of the Index data cannot be authorized with the Index *authValue*.
19	TPMA_NV_POLICYREAD	**SET (1):** The Index data may be read if the *authPolicy* is satisfied. **CLEAR (0):** Reading of the Index data cannot be authorized with the Index *authPolicy*.
24:20	Reserved	shall be zero reserved for future use
25	TPMA_NV_NO_DA	**SET (1):** Authorization failures of the Index do not affect the DA logic and authorization of the Index is not blocked when the TPM is in Lockout mode. **CLEAR (0):** Authorization failures of the Index will increment the authorization failure counter and authorizations of this Index are not allowed when the TPM is in Lockout mode.
26	TPMA_NV_ORDERLY	**SET (1):** NV Index state is only required to be saved when the TPM performs an orderly shutdown (TPM2_Shutdown()). **CLEAR (0):** NV Index state is required to be persistent after the command to update the Index completes successfully (that is, the NV update is synchronous with the update command).
27	TPMA_NV_CLEAR_STCLEAR	**SET (1):** TPMA_NV_WRITTEN for the Index is CLEAR by TPM Reset or TPM Restart. **CLEAR (0):** TPMA_NV_WRITTEN is not changed by TPM Restart. NOTE This attribute may only be SET if TPM_NT is not TPM_NT_COUNTER.
28	TPMA_NV_READLOCKED	**SET (1):** Reads of the Index are blocked until the next TPM Reset or TPM Restart. **CLEAR (0):** Reads of the Index are allowed if proper authorization is provided.
29	TPMA_NV_WRITTEN	**SET (1):** Index has been written. **CLEAR (0):** Index has not been written.
30	TPMA_NV_PLATFORMCREATE	**SET (1):** This Index may be undefined with Platform Authorization but not with Owner Authorization. **CLEAR (0):** This Index may be undefined using Owner Authorization but not with Platform Authorization. The TPM will validate that this attribute is SET when the Index is defined using Platform Authorization and will validate that this attribute is CLEAR when the Index is defined using Owner Authorization.
31	TPMA_NV_READ_STCLEAR	**SET (1):** TPM2_NV_ReadLock() may be used to SET TPMA_NV_READLOCKED for this Index. **CLEAR (0):** TPM2_NV_ReadLock() has no effect on this Index.

13.5 TPMS_NV_PUBLIC

This structure describes an NV Index.

Table 215 — Definition of TPMS_NV_PUBLIC Structure

Name	Type	Description
nvIndex	TPMI_RH_NV_INDEX	the handle of the data area
nameAlg	TPMI_ALG_HASH	hash algorithm used to compute the name of the Index and used for the *authPolicy.* For an extend index, the hash algorithm used for the extend.
attributes	TPMA_NV	the Index attributes
authPolicy	TPM2B_DIGEST	optional access policy for the Index The policy is computed using the *nameAlg* NOTE Shall be the Empty Policy if no authorization policy is present.
dataSize{:MAX_NV_INDEX_SIZE}	UINT16	the size of the data area The maximum size is implementation-dependent. The minimum maximum size is platform-specific.
#TPM_RC_SIZE		response code returned when the requested size is too large for the implementation

13.6 TPM2B_NV_PUBLIC

This structure is used when a TPMS_NV_PUBLIC is sent on the TPM interface.

Table 216 — Definition of TPM2B_NV_PUBLIC Structure

Name	Type	Description
size=	UINT16	size of *nvPublic*
nvPublic	TPMS_NV_PUBLIC	the public area

 Copyright © TCG 2006-2020

14 Context Data

14.1 Introduction

Clause 14 defines the contents of the TPM2_ContextSave() response parameters and TPM2_ContextLoad() command parameters.

If the parameters provided by the caller in TPM2_ContextLoad() do not match the values returned by the TPM when the context was saved, the integrity check of the TPM2B_CONTEXT will fail and the object or session will not be loaded.

14.2 TPM2B_CONTEXT_SENSITIVE

This structure holds the object or session context data. When saved, the full structure is encrypted.

NOTE This is an informative table that is included in the specification only to allow calculation of the maximum size for TPM2B_CONTEXT_DATA.

Table 217 — Definition of TPM2B_CONTEXT_SENSITIVE Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	
buffer[size]{:MAX_CONTEXT_SIZE}	BYTE	the sensitive data

14.3 TPMS_CONTEXT_DATA

This structure holds the integrity value and the encrypted data for a context.

NOTE This is an informative table that is included in the specification only to allow calculation of the maximum size for TPM2B_CONTEXT_DATA.

Table 218 — Definition of TPMS_CONTEXT_DATA Structure <IN/OUT>

Parameter	Type	Description
integrity	TPM2B_DIGEST	the integrity value
encrypted	TPM2B_CONTEXT_SENSITIVE	the sensitive area

14.4 TPM2B_CONTEXT_DATA

This structure is used in a TPMS_CONTEXT.

Table 219 — Definition of TPM2B_CONTEXT_DATA Structure <IN/OUT>

Parameter	Type	Description
size	UINT16	
buffer[size] {:sizeof(TPMS_CONTEXT_DATA)}	BYTE	

Copyright © TCG 2006-2020

14.5 TPMS_CONTEXT

This structure is used in TPM2_ContextLoad() and TPM2_ContextSave(). If the values of the TPMS_CONTEXT structure in TPM2_ContextLoad() are not the same as the values when the context was saved (TPM2_ContextSave()), then the TPM shall not load the context.

Saved object contexts shall not be loaded as long as the associated hierarchy is disabled.

Saved object contexts are invalidated when the Primary Seed of their hierarchy changes. Objects in the Endorsement hierarchy are invalidated when either the EPS or SPS is changed.

When an object has the *stClear* attribute, it shall not be possible to reload the context or any descendant object after a TPM Reset or TPM Restart.

NOTE 1 The reference implementation prevents reloads after TPM Restart by including the current value of a *clearCount* in the saved object context. When an object is loaded, this value is compared with the current value of the *clearCount* if the object has the *stClear* attribute. If the values are not the same, then the object cannot be loaded.

A sequence value is contained within *contextBlob*, the integrity-protected part of the saved context. The sequence value is repeated in the *sequence* parameter of the TPMS_CONTEXT structure. The *sequence* parameter, along with other values, is used in the generation the protection values of the context.

NOTE 2 The reference implementation prepends the *sequence* value to the *contextBlob* before, for example, the SESSION structure for sessions or the OBJECT structure for transient objects.

If the integrity value of the context is valid, but the *sequence* value of the decrypted context does not match the value in the *sequence* parameter, then TPM shall enter the failure mode because this is indicative of a specific type of attack on the context values.

NOTE 3 If the integrity value is correct, but the decryption fails and produces the wrong value for sequence, this implies that either the TPM is faulty or an external entity is able to forge an integrity value for the context but they have insufficient information to know the encryption key of the context. Since the TPM generated the valid context, then there is no reason for the sequence value in the context to be decrypted incorrectly other than the TPM is faulty or the TPM is under attack. In either case, it is appropriate for the TPM to enter failure more.

Table 220 — Definition of TPMS_CONTEXT Structure

Name	Type	Description
sequence	UINT64	the sequence number of the context NOTE Transient object contexts and session contexts used different counters.
savedHandle	TPMI_DH_SAVED	a handle indicating if the context is a session, object, or sequence object (see Table 221 — Context Handle Values
hierarchy	TPMI_RH_HIERARCHY+	the hierarchy of the context
contextBlob	TPM2B_CONTEXT_DATA	the context data and integrity HMAC

 Copyright © TCG 2006-2020

14.6 Parameters of TPMS_CONTEXT

14.6.1 *sequence*

The *sequence* parameter is used to differentiate the contexts and to allow the TPM to create a different encryption key for each context. Objects and sessions use different sequence counters. The sequence counter for objects (transient and sequence) is incremented when an object context is saved, and the sequence counter for sessions increments when a session is created or when it is loaded (TPM2_ContextLoad()). The session sequence number is the *contextID* counter.

For a session, the sequence number also allows the TRM to find the "older" contexts so that they may be refreshed if the *contextID* are too widely separated.

If an input value for *sequence* is larger than the value used in any saved context, the TPM shall return an error (TPM_RC_VALUE) and do no additional processing of the context.

If the context is a session context and the input value for sequence is less than the current value of *contextID* minus the maximum range for sessions, the TPM shall return an error (TPM_RC_VALUE) and do no additional processing of the context.

14.6.2 *savedHandle*

For a session, this is the handle that was assigned to the session when it was created. For a transient object, the handle will have one of the values shown in Table 221.

If the handle type for *savedHandle* is TPM_HT_TRANSIENT, then the low order bits are used to differentiate static objects from sequence objects.

If an input value for handle is outside of the range of values used by the TPM, the TPM shall return an error (TPM_RC_VALUE) and do no additional processing of the context.

Table 221 — Context Handle Values

Value	Description
0x02xxxxxx	an HMAC session context
0x03xxxxxx	a policy session context
0x80000000	an ordinary transient object
0x80000001	a sequence object
0x80000002	a transient object with the *stClear* attribute SET

 Copyright © TCG 2006-2020

14.6.3 *hierarchy*

This is the hierarchy (TPMI_RH_HIERARCHY) for the saved context and determines the proof value used in the construction of the encryption and integrity values for the context. For session and sequence contexts, the hierarchy is TPM_RC_NULL. The hierarchy for a transient object may be TPM_RH_NULL but it is not required.

14.7 Context Protection

14.7.1 Context Integrity

The integrity of the context blob is protected by an HMAC. The integrity value is constructed such that changes to the component values will invalidate the context and prevent it from being loaded.

Previously saved contexts for objects in the Platform hierarchy shall not be loadable after the PPS is changed.

Previously saved contexts for objects in the Storage hierarchy shall not be loadable after the SPS is changed.

Previously saved contexts for objects in the Endorsement hierarchy shall not be loadable after either the EPS or SPS is changed.

Previously saved sessions shall not be loadable after the SPS changes.

Previously saved contexts for objects that have their *stClear* attribute SET shall not be loadable after a TPM Restart. If a Storage Key has its *stClear* attribute SET, the descendants of this key shall not be loadable after TPM Restart.

Previously saved contexts for a session and objects shall not be loadable after a TPM Reset.

A saved context shall not be loaded if its HMAC is not valid. The equation for computing the HMAC for a context is found in “Context Integrity Protection” in TPM 2.0 Part 1.

14.7.2 Context Confidentiality

The context data of sessions and objects shall be protected by symmetric encryption using CFB. The method for computing the IV and encryption key is found in “Context Confidentiality Protection” in TPM 2.0 Part 1.

 Copyright © TCG 2006-2020

15 Creation Data

15.1 TPMS_CREATION_DATA

This structure provides information relating to the creation environment for the object. The creation data includes the parent Name, parent Qualified Name, and the digest of selected PCR. These values represent the environment in which the object was created. Creation data allows a relying party to determine if an object was created when some appropriate protections were present.

When the object is created, the structure shown in Table 222 is generated and a ticket is computed over this data.

If the parent is a permanent handle (TPM_RH_OWNER, TPM_RH_PLATFORM, TPM_RH_ENDORSEMENT, or TPM_RH_NULL), then *parentName* and *parentQualifiedName* will be set to the parent handle value and *parentNameAlg* will be TPM_ALG_NULL.

Table 222 — Definition of TPMS_CREATION_DATA Structure <OUT>

Parameter	Type	Description
pcrSelect	TPML_PCR_SELECTION	list indicating the PCR included in *pcrDigest*
pcrDigest	TPM2B_DIGEST	digest of the selected PCR using *nameAlg* of the object for which this structure is being created *pcrDigest.size* shall be zero if the *pcrSelect* list is empty.
locality	TPMA_LOCALITY	the locality at which the object was created
parentNameAlg	TPM_ALG_ID	*nameAlg* of the parent
parentName	TPM2B_NAME	Name of the parent at time of creation The size will match digest size associated with *parentNameAlg* unless it is TPM_ALG_NULL, in which case the size will be 4 and *parentName* will be the hierarchy handle.
parentQualifiedName	TPM2B_NAME	Qualified Name of the parent at the time of creation Size is the same as *parentName.*
outsideInfo	TPM2B_DATA	association with additional information added by the key creator This will be the contents of the *outsideInfo* parameter in TPM2_Create() or TPM2_CreatePrimary().

15.2 TPM2B_CREATION_DATA

This structure is created by TPM2_Create() and TPM2_CreatePrimary(). It is never entered into the TPM and never has a size of zero.

Table 223 — Definition of TPM2B_CREATION_DATA Structure <OUT>

Parameter	Type	Description
size=	UINT16	size of the creation data
creationData	TPMS_CREATION_DATA	

 Copyright © TCG 2006-2020

16 Attached Component Structures

16.1 TPM_AT

These constants are used in TPM2_AC_GetCapability() to indicate the first tagged value returned from an attached component.

TPM_AT values of 0x80000000 through 0xFFFFFFFF are reserved for vendor-specific values.

Table 224 — Definition of (UINT32) TPM_AT Constants

Name	Value	Comments
TPM_AT_ANY	0x00000000	in a command, a non-specific request for AC information; in a response, indicates that *outputData* is not meaningful
TPM_AT_ERROR	0x00000001	indicates a TCG defined, device-specific error
TPM_AT_PV1	0x00000002	indicates the most significant 32 bits of a pairing value for the AC
TPM_AT_VEND	0x80000000	value added to a TPM_AT to indicate a vendor-specific tag value

16.2 TPM_AE

These constants are the TCG-defined error values returned by an AC.

Table 225 — Definition of (UINT32) TPM_AE Constants <OUT>

Name	Value	Comments
TPM_AE_NONE	0x00000000	in a command, a non-specific request for AC information; in a response, indicates that *outputData* is not meaningful

16.3 TPMS_AC_OUTPUT

TPMS_AC_OUTPUT is used to return information about an AC. The *tag* structure parameter indicates the type of the *data* value.

Table 226 — Definition of TPMS_AC_OUTPUT Structure <OUT>

Parameter	Type	Description
tag	TPM_AT	tag indicating the contents of *data*
data	UINT32	the data returned from the AC

 Copyright © TCG 2006-2020

16.4 TPML_AC_CAPABILITIES

This list is only used in TPM2_AC_GetCapability().

The values in the list are returned in TPM_AT order (see Table 224) with vendor-specific values returned after TCG defined values.

NOTE MAX_AC_CAPABILITIES = MAX_CAP_DATA / sizeof(TPMS_AC_OUTPUT)

Table 227 — Definition of TPML_AC_CAPABILITIES Structure <OUT>

Parameter	Type	Description
count	UINT32	number of values in the *acCapabilities* list; may be 0
acCapabilities[count] {:MAX_AC_CAPABILITIES}	TPMS_AC_OUTPUT	a list of AC values

Trusted Platform Module Library
Part 3: Commands

1 Scope

This TPM 2.0 Part 3 of the *Trusted Platform Module Library* specification contains the definitions of the TPM commands. These commands make use of the constants, flags, structures, and union definitions defined in TPM 2.0 Part 2.

The detailed description of the operation of the commands is written in the C language with extensive comments. The behavior of the C code in this TPM 2.0 Part 3 is normative but does not fully describe the behavior of a TPM. The combination of this TPM 2.0 Part 3 and TPM 2.0 Part 4 is sufficient to fully describe the required behavior of a TPM.

The code in parts 3 and 4 is written to define the behavior of a compliant TPM. In some cases (e.g., firmware update), it is not possible to provide a compliant implementation. In those cases, any implementation provided by the vendor that meets the general description of the function provided in TPM 2.0 Part 3 would be compliant.

The code in parts 3 and 4 is not written to meet any particular level of conformance nor does this specification require that a TPM meet any particular level of conformance.

2 Terms and Definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

 Copyright © TCG 2006-2020

4 Notation

4.1 Introduction

For the purposes of this document, the notation given in TPM 2.0 Part 1 applies.

Command and response tables use various decorations to indicate the fields of the command and the allowed types. These decorations are described in this clause.

4.2 Table Decorations

The symbols and terms in the Notation column of Table 1 are used in the tables for the command schematics. These values indicate various qualifiers for the parameters or descriptions with which they are associated.

Table 1 — Command Modifiers and Decoration

Notation	Meaning
+	A Type decoration – When appended to a value in the Type column of a command, this symbol indicates that the parameter is allowed to use the “null” value of the data type (see in TPM 2.0 Part 2, *Conditional Types*). The null value is usually TPM_RH_NULL for a handle or TPM_ALG_NULL for an algorithm selector. NOTE This decoration is not appended to response parameters.
@	A Name decoration – When this symbol precedes a handle parameter in the “Name” column, it indicates that an authorization session is required for use of the entity associated with the handle. If a handle does not have this symbol, then an authorization session is not allowed.
+PP	A Description modifier – This modifier may follow TPM_RH_PLATFORM in the “Description” column to indicate that Physical Presence is required when *platformAuth*/*platformPolicy* is provided.
+{PP}	A Description modifier – This modifier may follow TPM_RH_PLATFORM to indicate that Physical Presence may be required when *platformAuth*/*platformPolicy* is provided. The commands with this notation may be in the *setList* or *clearList* of TPM2_PP_Commands().
{NV}	A Description modifier – This modifier may follow the *commandCode* in the “Description” column to indicate that the command may result in an update of NV memory and be subject to rate throttling by the TPM. If the command code does not have this notation, then a write to NV memory does not occur as part of the command actions. NOTE Any command that uses authorization may cause a write to NV if there is an authorization failure. A TPM may use the occasion of command execution to update the NV copy of clock.
{F}	A Description modifier – This modifier indicates that the “flushed” attribute will be SET in the TPMA_CC for the command. The modifier may follow the *commandCode* in the “Description” column to indicate that any transient handle context used by the command will be flushed from the TPM when the command completes. This may be combined with the {NV} modifier but not with the {E} modifier. EXAMPLE 1 {NV F} EXAMPLE 2 TPM2_SequenceComplete() will flush the context associated with the *sequenceHandle*.
{E}	A Description modifier – This modifier indicates that the “extensive” attribute will be SET in the TPMA_CC for the command. This modifier may follow the *commandCode* in the “Description” column to indicate that the command may flush many objects and re-enumeration of the loaded context likely will be required. This may be combined with the {NV} modifier but not with the {F} modifier. EXAMPLE 1 {NV E} EXAMPLE 2 TPM2_Clear() will flush all contexts associated with the Storage hierarchy and the Endorsement hierarchy.

 Copyright © TCG 2006-2020

Notation	Meaning
Auth Index:	A Description modifier – When a handle has a “@” decoration, the “Description” column will contain an “Auth Index:” entry for the handle. This entry indicates the number of the authorization session. The authorization sessions associated with handles will occur in the session area in the order of the handles with the “@” modifier. Sessions used only for encryption/decryption or only for audit will follow the handles used for authorization.
Auth Role:	A Description modifier – This will be in the “Description” column of a handle with the “@” decoration. It may have a value of USER, ADMIN or DUP. If the handle has the Auth Role of USER and the handle is an Object, the type of authorization is determined by the setting of *userWithAuth* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *userWithAuth* is SET. If the handle references an NV Index, then the allowed authorizations are determined by the settings of the attributes of the NV Index as described in TPM 2.0 Part 2, "TPMA_NV (NV Index Attributes)." If the Auth Role is ADMIN and the handle is an Object, the type of authorization is determined by the setting of *adminWithPolicy* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *adminWithPolicy* is SET. If the handle is an NV index, operation is as if *adminWithPolicy* is SET (see 5.6 e)2)). If the DUP role is selected, authorization may only be with a policy session (DUP role only applies to Objects). When either ADMIN or DUP role is selected, a policy command that selects the command being authorized is required to be part of the policy. EXAMPLE TPM2_Certify requires the ADMIN role for the first handle (*objectHandle*). The policy authorization for objectHandle is required to contain TPM2_PolicyCommandCode(*commandCode* == TPM_CC_Certify). This sets the state of the policy so that it can be used for ADMIN role authorization in TPM2_Certify().

4.3 Handle and Parameter Demarcation

The demarcations between the header, handle, and parameter parts are indicated by:

Table 2 — Separators

Separator	Meaning
(dashed line)	the values immediately following are in the handle area
(double line)	the values immediately following are in the parameter area

4.4 AuthorizationSize and ParameterSize

Authorization sessions are not shown in the command or response schematics. When the tag of a command or response is TPM_ST_SESSIONS, then a 32-bit value will be present in the command/response buffer to indicate the size of the authorization field or the parameter field. This value shall immediately follow the handle area (which may contain no handles). For a command, this value (*authorizationSize*) indicates the size of the Authorization Area and shall have a value of 9 or more. For a response, this value (*parameterSize*) indicates the size of the parameter area and may have a value of zero.

If the *authorizationSize* field is present in the command, *parameterSize* will be present in the response, but only if the *responseCode* is TPM_RC_SUCCESS.

When authorization is required to use the TPM entity associated with a handle, then at least one session will be present. To indicate this, the command *tag* Description field contains TPM_ST_SESSIONS. Addional sessions for audit, encrypt, and decrypt may be present.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

When the command *tag* Description field contains TPM_ST_NO_SESSIONS, then no sessions are allowed and the *authorizationSize* field is not present.

When a command allows use of sessions when not required, the command *tag* Description field will indicate the types of sessions that may be used with the command.

4.5 Return Code Alias

For the RC_FMT1 return codes that may add a parameter, handle, or session number, the prefix TPM_RCS_ is an alias for TPM_RC_.

TPM_RC_n is added, where n is the parameter, handle, or session number. In addition, TPM_RC_H is added for handle, TPM_RC_P for parameter, and TPM_RC_S for session errors.

NOTE TPM_RCS_ is a programming convention. Programmers should only add numbers to TPM_RCS_ return codes, never TPM_RC_ return codes. Only return codes that can have a number added have the TPM_RCS_ alias defined. Attempting to use a TPM_RCS_ return code that does not have the TPM_RCS_ alias will cause a compiler error.

EXAMPLE 1 Since TPM_RC_VALUE can have a number added, TPM_RCS_VALUE is defined. A program can use the construct "TPM_RCS_VALUE + number". Since TPM_RC_SIGNATURE cannot have a number added, TPM_RCS_SIGNATURE is not defined. A program using the construct "TPM_RCS_SIGNATURE + number" will not compile, alerting the programmer that the construct is incorrect.

By convention, the number to be added is of the form RC_CommandName_ParameterName where CommmandName is the name of the command with the TPM2_ prefix removed. The parameter name alone is insufficient because the same parameter name could be in a different position in different commands.

EXAMPLE 2 TPM2_HMAC_Start with parameters that result in TPM_ALG_NULL as the hash algorithm will returns TPM_RC_VALUE plus the parameter number. Since *hashAlg* is the second parameter, This code results:

```
#define RC_HMAC_Start_hashAlg          (TPM_RC_P + TPM_RC_2)

return TPM_RCS_VALUE + RC_HMAC_Start_hashAlg;
```

5 Command Processing

5.1 Introduction

This clause defines the command validations that are required of any implementation and the response code returned if the indicated check fails. Unless stated otherwise, the order of the checks is not normative and different TPM may give different responses when a command has multiple errors.

In the description below, some statements that describe a check may be followed by a response code in parentheses. This is the normative response code should the indicated check fail. A normative response code may also be included in the statement.

5.2 Command Header Validation

Before a TPM may begin the actions associated with a command, a set of command format and consistency checks shall be performed. These checks are listed below and should be performed in the indicated order.

a) The TPM shall successfully unmarshal a TPMI_ST_COMMAND_TAG and verify that it is either TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS (TPM_RC_BAD_TAG).

 Copyright © TCG 2006-2020

b) The TPM shall successfully unmarshal a UINT32 as the *commandSize*. If the TPM has an interface buffer that is loaded by some hardware process, the number of octets in the input buffer for the command reported by the hardware process shall exactly match the value in *commandSize* (TPM_RC_COMMAND_SIZE).

NOTE A TPM may have direct access to system memory and unmarshal directly from that memory.

c) The TPM shall successfully unmarshal a TPM_CC and verify that the command is implemented (TPM_RC_COMMAND_CODE).

5.3 Mode Checks

The following mode checks shall be performed in the order listed:

a) If the TPM is in Failure mode, then the *commandCode* is TPM_CC_GetTestResult or TPM_CC_GetCapability (TPM_RC_FAILURE) and the command *tag* is TPM_ST_NO_SESSIONS (TPM_RC_FAILURE).

NOTE 1 In Failure mode, the TPM has no cryptographic capability and processing of sessions is not supported.

b) The TPM is in Field Upgrade mode (FUM), the *commandCode* is TPM_CC_FieldUpgradeData (TPM_RC_UPGRADE).

c) If the TPM has not been initialized (TPM2_Startup()), then the *commandCode* is TPM_CC_Startup (TPM_RC_INITIALIZE).

NOTE 2 The TPM may enter Failure mode during _TPM_Init processing, before TPM2_Startup(). Since the platform firmware cannot know that the TPM is in Failure mode without accessing it, and since the first command is required to be TPM2_Startup(), the expected sequence will be that platform firmware (the CRTM) will issue TPM2_Startup() and receive TPM_RC_FAILURE indicating that the TPM is in Failure mode.

There may be failures where a TPM cannot record that it received TPM2_Startup(). In those cases, a TPM in failure mode may process TPM2_GetTestResult(), TPM2_GetCapability(), or the field upgrade commands. As a side effect, that TPM may process TPM2_GetTestResult(), TPM2_GetCapability() or the field upgrade commands before TPM2_Startup().

This is a corner case exception to the rule that TPM2_Startup() must be the first command.

The mode checks may be performed before or after the command header validation.

5.4 Handle Area Validation

After successfully unmarshaling and validating the command header, the TPM shall perform the following checks on the handles and sessions. These checks may be performed in any order.

NOTE 1 A TPM is required to perform the handle area validation before the authorization checks because an authorization cannot be performed unless the authorization values and attributes for the referenced entity are known by the TPM. For them to be known, the referenced entity must be in the TPM and accessible.

a) The TPM shall successfully unmarshal the number of handles required by the command and validate that the value of the handle is consistent with the command syntax. If not, the TPM shall return TPM_RC_VALUE.

NOTE 2 The TPM may unmarshal a handle and validate that it references an entity on the TPM before unmarshaling a subsequent handle.

NOTE 3 If the submitted command contains fewer handles than required by the syntax of the command, the TPM may continue to read into the next area and attempt to interpret the data as a handle.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

b) For all handles in the handle area of the command, the TPM will validate that the referenced entity is present in the TPM.

1) If the handle references a transient object, the handle shall reference a loaded object (TPM_RC_REFERENCE_H0 + N where N is the number of the handle in the command).

NOTE 4 If the hierarchy for a transient object is disabled, then the transient objects will be flushed so this check will fail.

2) If the handle references a persistent object, then

i) the hierarchy associated with the object (platform or storage, based on the handle value) is enabled (TPM_RC_HANDLE);

ii) the handle shall reference a persistent object that is currently in TPM non-volatile memory (TPM_RC_HANDLE);

iii) if the handle references a persistent object that is associated with the endorsement hierarchy, that the endorsement hierarchy is not disabled (TPM_RC_HANDLE); and

NOTE 5 The reference implementation keeps an internal attribute, passed down from a primary key to its descendents, indicating the object's hierarchy.

iv) if the TPM implementation moves a persistent object to RAM for command processing then sufficient RAM space is available (TPM_RC_OBJECT_MEMORY).

3) If the handle references an NV Index, then

i) an Index exists that corresponds to the handle (TPM_RC_HANDLE); and

ii) the hierarchy associated with the existing NV Index is not disabled (TPM_RC_HANDLE).

iii) If the command requires write access to the index data then TPMA_NV_WRITELOCKED is not SET (TPM_RC_NV_LOCKED)

iv) If the command requires read access to the index data then TPMA_NV_READLOCKED is not SET (TPM_RC_NV_LOCKED)

4) If the handle references a session, then the session context shall be present in TPM memory (TPM_RC_REFERENCE_H0 + N).

5) If the handle references a primary seed for a hierarchy (TPM_RH_ENDORSEMENT, TPM_RH_OWNER, or TPM_RH_PLATFORM) then the enable for the hierarchy is SET (TPM_RC_HIERARCHY).

6) If the handle references a PCR, then the value is within the range of PCR supported by the TPM (TPM_RC_VALUE)

NOTE 6 In the reference implementation, this TPM_RC_VALUE is returned by the unmarshaling code for a TPMI_DH_PCR.

5.5 Session Area Validation

a) If the tag is TPM_ST_SESSIONS and the command requires TPM_ST_NO_SESSIONS, the TPM will return TPM_RC_AUTH_CONTEXT.

b) If the tag is TPM_ST_NO_SESSIONS and the command requires TPM_ST_SESSIONS, the TPM will return TPM_RC_AUTH_MISSING.

c) If the tag is TPM_ST_SESSIONS, the TPM will attempt to unmarshal an *authorizationSize* and return TPM_RC_AUTHSIZE if the value is not within an acceptable range.

1) The minimum value is (sizeof(TPM_HANDLE) + sizeof(UINT16) + sizeof(TPMA_SESSION) + sizeof(UINT16)).

 Copyright © TCG 2006-2020

2) The maximum value of authorizationSize is equal to commandSize – (sizeof(TPM_ST) + sizeof(UINT32) + sizeof(TPM_CC) + (N * sizeof(TPM_HANDLE)) + sizeof(UINT32)) where N is the number of handles associated with the *commandCode* and may be zero.

NOTE 1 (sizeof(TPM_ST) + sizeof(UINT32) + sizeof(TPM_CC)) is the size of a command header. The last UINT32 contains the authorizationSize octets, which are not counted as being in the authorization session area.

d) The TPM will unmarshal the authorization sessions and perform the following validations:

1) If the session handle is not a handle for an HMAC session, a handle for a policy session, or, TPM_RS_PW then the TPM shall return TPM_RC_HANDLE.

2) If the session is not loaded, the TPM will return the warning TPM_RC_REFERENCE_S0 + N where N is the number of the session. The first session is session zero, N = 0.

NOTE 2 If the HMAC and policy session contexts use the same memory, the type of the context must match the type of the handle.

3) If the maximum allowed number of sessions have been unmarshaled and fewer octets than indicated in *authorizationSize* were unmarshaled (that is, *authorizationSize* is too large), the TPM shall return TPM_RC_AUTHSIZE.

4) The consistency of the authorization session attributes is checked.

i) Only one session is allowed for:

(a) session auditing (TPM_RC_ATTRIBUTES) – this session may be used for encrypt or decrypt but may not be a session that is also used for authorization;

(b) decrypting a command parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session, or a session may be added for the single purpose of decrypting a command parameter, as long as the total number of sessions does not exceed three; and

(c) encrypting a response parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session if present, ora session may be added for the single purpose of encrypting a response parameter, as long as the total number of sessions does not exceed three.

NOTE 3 A session used for decrypting a command parameter may also be used for encrypting a response parameter.

ii) If a session is not being used for authorization, at least one of decrypt, encrypt, or audit must be SET. (TPM_RC_ATTRIBUTES).

5) An authorization session is present for each of the handles with the “@” decoration (TPM_RC_AUTH_MISSING).

5.6 Authorization Checks

After unmarshaling and validating the handles and the consistency of the authorization sessions, the authorizations shall be checked. Authorization checks only apply to handles if the handle in the command schematic has the “@” decoration. Authorization checks must be performed in this order.

a) The public and sensitive portions of the object shall be present on the TPM (TPM_RC_AUTH_UNAVAILABLE).

b) If the associated handle is TPM_RH_PLATFORM, and the command requires confirmation with physical presence, then physical presence is asserted (TPM_RC_PP).

c) If the object or NV Index is subject to DA protection, and the authorization is with an HMAC or password, then the TPM is not in lockout (TPM_RC_LOCKOUT).

 Copyright © TCG 2006-2020

NOTE 1 An object is subject to DA protection if its *noDA* attribute is CLEAR. An NV Index is subject to DA protection if its TPMA_NV_NO_DA attribute is CLEAR.

NOTE 2 An HMAC or password is required in a policy session when the policy contains TPM2_PolicyAuthValue() or TPM2_PolicyPassword().

d) If the command requires a handle to have DUP role authorization, then the associated authorization session is a policy session (TPM_RC_AUTH_TYPE).

e) If the command requires a handle to have ADMIN role authorization:

1) If the entity being authorized is an object and its *adminWithPolicy* attribute is SET, or a hierarchy, then the authorization session is a policy session (TPM_RC_AUTH_TYPE).

NOTE 3 If adminWithPolicy is CLEAR, then any type of authorization session is allowed.

2) If the entity being authorized is an NV Index, then the associated authorization session is a policy session.

NOTE 4 The only commands that are currently defined that require use of ADMIN role authorization are commands that operate on objects and NV Indices.

f) If the command requires a handle to have USER role authorization:

1) If the entity being authorized is an object and its *userWithAuth* attribute is CLEAR, then the associated authorization session is a policy session (TPM_RC_POLICY_FAIL).

NOTE 5 There is no check for a hierarchy, because a hierarchy operates as if userWithAuth is SET.

2) If the entity being authorized is an NV Index;

i) if the authorization session is a policy session;

(a) the TPMA_NV_POLICYWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

(b) the TPMA_NV_POLICYREAD attribute of the NV Index is SET if the command reads the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

ii) if the authorization is an HMAC session or a password;

(a) the TPMA_NV_AUTHWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

(b) the TPMA_NV_AUTHREAD attribute of the NV Index is SET if the command reads the NV Index data (TPM_RC_AUTH_UNAVAILABLE).

g) If the authorization is provided by a policy session, then:

1) if *policySession→timeOut* has been set, the session shall not have expired (TPM_RC_EXPIRED);

2) if *policySession→cpHash* has been set, it shall match the *cpHash* of the command (TPM_RC_POLICY_FAIL);

3) if *policySession→commandCode* has been set, then *commandCode* of the command shall match (TPM_RC_POLICY_CC);

4) *policySession→policyDigest* shall match the *authPolicy* associated with the handle (TPM_RC_POLICY_FAIL);

5) if *policySession→pcrUpdateCounter* has been set, then it shall match the value of *pcrUpdateCounter* (TPM_RC_PCR_CHANGED);

6) if *policySession→commandLocality* has been set, it shall match the locality of the command (TPM_RC_LOCALITY),

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

7) if *policySession→cpHash* contains a template, and the command is TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded(), then the *inPublic* parmeter matches the contents of *policySession→cpHash;* and

8) if the policy requires that an authValue be provided in order to satisfy the policy, then *session.hmac* is not an Empty Buffer.

h) If the authorization uses an HMAC, then the HMAC is properly constructed using the *authValue* associated with the handle and/or the session secret (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

NOTE 6 A policy session may require proof of knowledge of the authValue of the object being authorized.

i) If the authorization uses a password, then the password matches the *authValue* associated with the handle (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

If the TPM returns an error other than TPM_RC_AUTH_FAIL then the TPM shall not alter any TPM state. If the TPM return TPM_RC_AUTH_FAIL, then the TPM shall not alter any TPM state other than *lockoutCount*.

NOTE 7 The TPM may decrease failedTries regardless of any other processing performed by the TPM. That is, the TPM may exit Lockout mode, regardless of the return code.

5.7 Parameter Decryption

If an authorization session has the TPMA_SESSION.*decrypt* attribute SET, and the command does not allow a command parameter to be encrypted, then the TPM will return TPM_RC_ATTRIBUTES. Otherwise, the TPM will decrypt the parameter using the values associated with the session before parsing parameters.

NOTE The size of the parameter to be encrypted can be zero.

5.8 Parameter Unmarshaling

5.8.1 Introduction

The detailed actions for each command assume that the input parameters of the command have been unmarshaled into a command-specific structure with the structure defined by the command schematic. Additionally, a response-specific output structure is assumed which will receive the values produced by the detailed actions.

NOTE An implementation is not required to process parameters in this manner or to separate the parameter parsing from the command actions. This method was chosen for the specification so that the normative behavior described by the detailed actions would be clear and unencumbered.

Unmarshaling is the process of processing the parameters in the input buffer and preparing the parameters for use by the command-specific action code. No data movement need take place but it is required that the TPM validate that the parameters meet the requirements of the expected data type as defined in TPM 2.0 Part 2.

 Copyright © TCG 2006-2020

5.8.2 Unmarshaling Errors

When an error is encountered while unmarshaling a command parameter, an error response code is returned and no command processing occurs. A table defining a data type may have response codes embedded in the table to indicate the error returned when the input value does not match the parameters of the table.

NOTE In the reference implementation, a parameter number is added to the response code so that the offending parameter can be isolated. This is optional.

In many cases, the table contains no specific response code value and the return code will be determined as defined in Table 3.

Table 3 — Unmarshaling Errors

Response Code	Meaning
TPM_RC_ASYMMETRIC	a parameter that should be an asymmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_BAD_TAG	a parameter that should be a command tag selection has a value that is not supported by the TPM
TPM_RC_COMMAND_CODE	a parameter that should be a command code does not have a value that is supported by the TPM
TPM_RC_HASH	a parameter that should be a hash algorithm selection does not have a value that is supported by the TPM
TPM_RC_INSUFFICIENT	the input buffer did not contain enough octets to allow unmarshaling of the expected data type;
TPM_RC_KDF	a parameter that should be a key derivation scheme (KDF) selection does not have a value that is supported by the TPM
TPM_RC_KEY_SIZE	a parameter that is a key size has a value that is not supported by the TPM
TPM_RC_MODE	a parameter that should be a symmetric encryption mode selection does not have a value that is supported by the TPM
TPM_RC_RESERVED	a non-zero value was found in a reserved field of an attribute structure (TPMA_)
TPM_RC_SCHEME	a parameter that should be signing or encryption scheme selection does not have a value that is supported by the TPM
TPM_RC_SIZE	the value of a size parameter is larger or smaller than allowed
TPM_RC_SYMMETRIC	a parameter that should be a symmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_TAG	a parameter that should be a structure tag has a value that is not supported by the TPM
TPM_RC_TYPE	The type parameter of a TPMT_PUBLIC or TPMT_SENSITIVE has a value that is not supported by the TPM
TPM_RC_VALUE	a parameter does not have one of its allowed values

In some commands, a parameter may not be used because of various options of that command. However, the unmarshaling code is required to validate that all parameters have values that are allowed by the TPM 2.0 Part 2 definition of the parameter type even if that parameter is not used in the command actions.

 Copyright © TCG 2006-2020

5.9 Command Post Processing

When the code that implements the detailed actions of the command completes, it returns a response code. If that code is not TPM_RC_SUCCESS, the post processing code will not update any session or audit data and will return a 10-octet response packet.

If the command completes successfully, the tag of the command determines if any authorization sessions will be in the response. If so, the TPM will encrypt the first parameter of the response if indicated by the authorization attributes. The TPM will then generate a new nonce value for each session and, if appropriate, generate an HMAC.

If authorization HMAC computations are performed on the response, the HMAC keys used in the response will be the same as the HMAC keys used in processing the HMAC in the command.

NOTE 1 This primarily affects authorizations associated with a first write to an NV Index using a bound session. The computation of the HMAC in the response is performed as if the Name of the Index did not change as a consequence of the command actions. The session binding to the NV Index will not persist to any subsequent command.

NOTE 2 The authorization attributes were validated during the session area validation to ensure that only one session was used for parameter encryption of the response and that the command allowed encryption in the response.

NOTE 3 No session nonce value is used for a password authorization but the session data is present.

Additionally, if the command is being audited by Command Audit, the audit digest is updated with the *cpHash* of the command and *rpHash* of the response.

 Copyright © TCG 2006-2020

6 Response Values

6.1 Tag

When a command completes successfully, the *tag* parameter in the response shall have the same value as the *tag* parameter in the command (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). When a command fails (the responseCode is not TPM_RC_SUCCESS), then the *tag* parameter in the response shall be TPM_ST_NO_SESSIONS.

A special case exists when the command *tag* parameter is not an allowed value (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). For this case, it is assumed that the system software is attempting to send a command formatted for a TPM 1.2 but the TPM is not capable of executing TPM 1.2 commands. So that the TPM 1.2 compatible software will have a recognizable response, the TPM sets *tag* to TPM_ST_RSP_COMMAND, *responseSize* to 00 00 00 $0A_{16}$ and *responseCode* to TPM_RC_BAD_TAG. This is the same response as the TPM 1.2 fatal error for TPM_BADTAG.

6.2 Response Codes

The normal response for any command is TPM_RC_SUCCESS. Any other value indicates that the command did not complete and the state of the TPM is unchanged. An exception to this general rule is that the logic associated with dictionary attack protection is allowed to be modified when an authorization failure occurs.

Commands have response codes that are specific to that command, and those response codes are enumerated in the detailed actions of each command. The codes associated with the unmarshaling of parameters are documented Table 3. Another set of response code values are not command specific and indicate a problem that is not specific to the command. That is, if the indicated problem is remedied, the same command could be resubmitted and may complete normally.

The response codes that are not command specific are listed and described in

Table 4.

The reference code for the command actions may have code that generates specific response codes associated with a specific check but the listing of responses may not have that response code listed.

 Copyright © TCG 2006-2020

Table 4 — Command-Independent Response Codes

Response Code	Meaning
TPM_RC_CANCELED	This response code may be returned by a TPM that supports command cancel. When the TPM receives an indication that the current command should be cancelled, the TPM may complete the command or return this code. If this code is returned, then the TPM state is not changed and the same command may be retried.
TPM_RC_CONTEXT_GAP	This response code can be returned for commands that manage session contexts. It indicates that the gap between the lowest numbered active session and the highest numbered session is at the limits of the session tracking logic. The remedy is to load the session context with the lowest number so that its tracking number can be updated.
TPM_RC_LOCKOUT	This response indicates that authorizations for objects subject to DA protection are not allowed at this time because the TPM is in DA lockout mode. The remedy is to wait or to exeucte TPM2_DictionaryAttackLockoutReset().
TPM_RC_MEMORY	A TPM may use a common pool of memory for objects, sessions, and other purposes. When the TPM does not have enough memory available to perform the actions of the command, it may return TPM_RC_MEMORY. This indicates that the TPM resource manager may flush either sessions or objects in order to make memory available for the command execution. A TPM may choose to return TPM_RC_OBJECT_MEMORY or TPM_RC_SESSION_MEMORY if it needs contexts of a particular type to be flushed.
TPM_RC_NV_RATE	This response code indicates that the TPM is rate-limiting writes to the NV memory in order to prevent wearout. This response is possible for any command that explicity writes to NV or commands that incidentally use NV such as a command that uses authorization session that may need to update the dictionary attack logic.
TPM_RC_NV_UNAVAILABLE	This response code is similar to TPM_RC_NV_RATE but indicates that access to NV memory is currently not available and the command is not allowed to proceed until it is. This would occur in a system where the NV memory used by the TPM is not exclusive to the TPM and is a shared system resource.
TPM_RC_OBJECT_HANDLES	This response code indicates that the TPM has exhausted its handle space and no new objects can be loaded unless the TPM is rebooted. This does not occur in the reference implementation because of the way that object handles are allocated. However, other implementations are allowed to assign each object a unique handle each time the object is loaded. A TPM using this implementation would be able to load 2^{24} objects before the object space is exhausted.
TPM_RC_OBJECT_MEMORY	This response code can be returned by any command that causes the TPM to need an object 'slot'. The most common case where this might be returned is when an object is loaded (TPM2_Load, TPM2_CreatePrimary(), or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other reasons. In the reference implementation, the TPM copies a referenced persistent object into RAM for the duration of the commannd. If all the slots are previously occupied, the TPM may return this value. A TPM is allowed to use object slots for other purposes and return this value. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_REFERENCE_Hx	This response code indicates that a handle in the handle area of the command is not associated with a loaded object. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1st handle and 6 representing the 7th. Upper values are provided for future use. The TPM resource manager needs to find the correct object and load it. It may then adjust the handle and retry the command. NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

Response Code	**Meaning**
TPM_RC_REFERENCE_Sx	This response code indicates that a handle in the session area of the command is not associated with a loaded session. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1st session handle and 6 representing the 7th. Upper values are provided for future use. The TPM resource manager needs to find the correct session and load it. It may then retry the command. NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.
TPM_RC_RETRY	the TPM was not able to start the command
TPM_RC_SESSION_HANDLES	This response code indicates that the TPM does not have a handle to assign to a new session. This respose is only returned by TPM2_StartAuthSession(). It is listed here because the command is not in error and the TPM resource manager can remedy the situation by flushing a session (TPM2_FlushContext().
TPM_RC_SESSION_MEMORY	This response code can be returned by any command that causes the TPM to need a session 'slot'. The most common case where this might be returned is when a session is loaded (TPM2_StartAuthSession() or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other purposes. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_SUCCESS	Normal completion for any command. If the responseCode is TPM_RC_SUCCESS, then the rest of the response has the format indicated in the response schematic. Otherwise, the response is a 10 octet value indicating an error.
TPM_RC_TESTING	This response code indicates that the TPM is performing tests and cannot respond to the request at this time. The command may be retried.
TPM_RC_YIELDED	the TPM has suspended operation on the command; forward progress was made and the command may be retried. See TPM 2.0 Part 1, “Multi-tasking.” NOTE This cannot occur on the reference implementation.

7 Implementation Dependent

The actions code for each command makes assumptions about the behavior of various sub-systems. There are many possible implementations of the subsystems that would achieve equivalent results. The actions code is not written to anticipate all possible implementations of the sub-systems. Therefore, it is the responsibility of the implementer to ensure that the necessary changes are made to the actions code when the sub-system behavior changes.

 Copyright © TCG 2006-2020

8 Detailed Actions Assumptions

8.1 Introduction

The C code in the Detailed Actions for each command is written with a set of assumptions about the processing performed before the action code is called and the processing that will be done after the action code completes.

8.2 Pre-processing

Before calling the command actions code, the following actions have occurred.

- Verification that the handles in the handle area reference entities that are resident on the TPM.
- NOTE If a handle is in the parameter portion of the command, the associated entity does not have to be loaded, but the handle is required to be the correct type.
- If use of a handle requires authorization, the Password, HMAC, or Policy session associated with the handle has been verified.
- If a command parameter was encrypted using parameter encryption, it was decrypted before being unmarshaled.
- If the command uses handles or parameters, the calling stack contains a pointer to a data structure (*in*) that holds the unmarshaled values for the handles and command parameters. If the response has handles or parameters, the calling stack contains a pointer to a data structure (*out*) to hold the handles and response parameters generated by the command.
- All parameters of the *in* structure have been validated and meet the requirements of the parameter type as defined in TPM 2.0 Part 2.
- Space set aside for the out structure is sufficient to hold the largest *out* structure that could be produced by the command

8.3 Post Processing

When the function implementing the command actions completes,

- response parameters that require parameter encryption will be encrypted after the command actions complete;
- audit and session contexts will be updated if the command response is TPM_RC_SUCCESS; and
- the command header and command response parameters will be marshaled to the response buffer.

9 Start-up

9.1 Introduction

This clause contains the commands used to manage the startup and restart state of a TPM.

9.2 _TPM_Init

9.2.1 General Description

_TPM_Init initializes a TPM.

Initialization actions include testing code required to execute the next expected command. If the TPM is in FUM, the next expected command is TPM2_FieldUpgradeData(); otherwise, the next expected command is TPM2_Startup().

NOTE 1 If the TPM performs self-tests after receiving _TPM_Init() and the TPM enters Failure mode before receiving TPM2_Startup() or TPM2_FieldUpgradeData(), then the TPM may be able to accept TPM2_GetTestResult() or TPM2_GetCapability().

The means of signaling _TPM_Init shall be defined in the platform-specific specifications that define the physical interface to the TPM. The platform shall send this indication whenever the platform starts its boot process and only when the platform starts its boot process.

There shall be no software method of generating this indication that does not also reset the platform and begin execution of the CRTM.

NOTE 2 In the reference implementation, this signal causes an internal flag (*s_initialized*) to be CLEAR. While this flag is CLEAR, the TPM will only accept the next expected command described above.

9.2.2 Detailed Actions

```
1  #include "Tpm.h"
2  #include "_TPM_Init_fp.h"
3   // This function is used to process a _TPM_Init indication.
4  LIB_EXPORT void
5  _TPM_Init(
6      void
7      )
8  {
9      g_powerWasLost = g_powerWasLost | _plat__WasPowerLost();
10
11 #if SIMULATION && DEBUG
12     // If power was lost and this was a simulation, put canary in RAM used by NV
13     // so that uninitialized memory can be detected more easily
14     if(g_powerWasLost)
15     {
16         memset(&gc, 0xbb, sizeof(gc));
17         memset(&gr, 0xbb, sizeof(gr));
18         memset(&gp, 0xbb, sizeof(gp));
19         memset(&go, 0xbb, sizeof(go));
20     }
21 #endif
22
23 #if SIMULATION
24     // Clear the flag that forces failure on self-test
25     g_forceFailureMode = FALSE;
26 #endif
27
28     // Disable the tick processing
29     _plat__ACT_EnableTicks(FALSE);
30
31     // Set initialization state
32     TPMInit();
33
34     // Set g_DRTMHandle as unassigned
35     g_DRTMHandle = TPM_RH_UNASSIGNED;
36
37     // No H-CRTM, yet.
38     g_DrtmPreStartup = FALSE;
39
40     // Initialize the NvEnvironment.
41     g_nvOk = NvPowerOn();
42
43     // Initialize cryptographic functions
44     g_inFailureMode = (CryptInit() == FALSE);
45     if(!g_inFailureMode)
46     {
47         // Load the persistent data
48         NvReadPersistent();
49
50         // Load the orderly data (clock and DRBG state).
51         // If this is not done here, things break
52         NvRead(&go, NV_ORDERLY_DATA, sizeof(go));
53
54         // Start clock. Need to do this after NV has been restored.
55         TimePowerOn();
56     }
57     return;
58 }
```

9.3 TPM2_Startup

9.3.1 General Description

TPM2_Startup() is always preceded by _TPM_Init, which is the physical indication that TPM initialization is necessary because of a system-wide reset. TPM2_Startup() is only valid after _TPM_Init. Additional TPM2_Startup() commands are not allowed after it has completed successfully. If a TPM requires TPM2_Startup() and another command is received, or if the TPM receives TPM2_Startup() when it is not required, the TPM shall return TPM_RC_INITIALIZE.

NOTE 1 See 9.2.1 for other command options for a TPM supporting field upgrade mode.

NOTE 2 _TPM_Hash_Start, _TPM_Hash_Data, and _TPM_Hash_End are not commands and a platform-specific specification may allow these indications between _TPM_Init and TPM2_Startup().

If in Failure mode, the TPM shall accept TPM2_GetTestResult() and TPM2_GetCapability() even if TPM2_Startup() is not completed successfully or processed at all.

A platform-specific specification may restrict the localities at which TPM2_Startup() may be received.

A Shutdown/Startup sequence determines the way in which the TPM will operate in response to TPM2_Startup(). The three sequences are:

1) TPM Reset – This is a Startup(CLEAR) preceded by either Shutdown(CLEAR) or no TPM2_Shutdown(). On TPM Reset, all variables go back to their default initialization state.

   NOTE 3 Only those values that are specified as having a default initialization state are changed by TPM Reset. Persistent values that have no default initialization state are not changed by this command. Values such as seeds have no default initialization state and only change due to specific commands.

2) TPM Restart – This is a Startup(CLEAR) preceded by Shutdown(STATE). This preserves much of the previous state of the TPM except that PCR and the controls associated with the Platform hierarchy are all returned to their default initialization state;

3) TPM Resume – This is a Startup(STATE) preceded by Shutdown(STATE). This preserves the previous state of the TPM including the static Root of Trust for Measurement (S-RTM) PCR and the platform controls other than the *phEnable*.

If a TPM receives Startup(STATE) and that was not preceded by Shutdown(STATE), the TPM shall return TPM_RC_VALUE.

If, during TPM Restart or TPM Resume, the TPM fails to restore the state saved at the last Shutdown(STATE), the TPM shall enter Failure Mode and return TPM_RC_FAILURE.

On any TPM2_Startup(),

- *phEnable* shall be SET;
- all transient contexts (objects, sessions, and sequences) shall be flushed from TPM memory;

NOTE 4 See Part 1 Time for a description of the TPMS_TIME_INFO.*time* behaviour.

- use of *lockoutAuth* shall be enabled if *lockoutRecovery* is zero.

Additional actions are performed based on the Shutdown/Startup sequence.

 Copyright © TCG 2006-2020

On TPM Reset:

- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- For each NV Index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV Index with TPMA_NV_ORDERLY SET, TPMA_NV_WRITTEN shall be CLEAR unless the type is TPM_NT_COUNTER,
- On a disorderly reset, advance the orderly counters,
- For each NV Index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR,
- tracking data for saved session contexts shall be set to its initial value,
- the object context sequence number is reset to zero,
- a new context encryption key shall be generated,
- TPMS_CLOCK_INFO.*restartCount* shall be reset to zero,
- TPMS_CLOCK_INFO.*resetCount* shall be incremented,
- the PCR Update Counter shall be clear to zero,

  NOTE 5 Because the PCR update counter may be incremented when a PCR is reset, the PCR resets performed as part of this command can result in the PCR update counter being non-zero at the end of this command.

- *phEnableNV, shEnable* and *ehEnable* shall be SET, and
- PCR in all banks are reset to their default initial conditions as determined by the relevant platform-specific specification and the H-CRTM state (for exceptions, see TPM 2.0 Part 1*, H-CRTM before TPM2_Startup() and TPM2_Startup without H-CRTM*),
- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR (if *preserveSignaled* is CLEAR), and the *authPolicy* is set to the Empty Buffer and its hashAlg is set to TPM_ALG_NULL.

  NOTE 6 PCR may be initialized any time between _TPM_Init and the end of TPM2_Startup(). PCR that are preserved by TPM Resume will need to be restored during TPM2_Startup().

  NOTE 7 See "Initializing PCR" in TPM 2.0 Part 1 for a description of the default initial conditions for a PCR.

 Copyright © TCG 2006-2020

On TPM Restart:

- TPMS_CLOCK_INFO.*restartCount* shall be incremented,
- *phEnableNV, shEnable* and *ehEnable* shall be SET,
- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- For each NV index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR, and
- PCR in all banks are reset to their default initial conditions.
- If an H-CRTM Event Sequence is active, extend the PCR designated by the platform-specific specification.
- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR (if *preserveSignaled* is CLEAR), and the *authPolicy* is set to the Empty Buffer and its hashAlg is set to TPM_ALG_NULL.

On TPM Resume:

- the H-CRTM startup method is the same for this TPM2_Startup() as for the previous TPM2_Startup(); (TPM_RC_LOCALITY)
- TPMS_CLOCK_INFO.*restartCount* shall be incremented; and
- PCR that are specified in a platform-specific specification to be preserved on TPM Resume are restored to their saved state and other PCR are set to their initial value as determined by a platform-specific specification. For constraints, see TPM 2.0 Part 1, *H-CRTM before TPM2_Startup() and TPM2_Startup without H-CRTM.*
- The ACT timeout, the ACT *signaled* attribute and the ACT specific *authPolicy* values are preserved.

Other TPM state may change as required to meet the needs of the implementation.

If the *startupType* is TPM_SU_STATE and the TPM requires TPM_SU_CLEAR, then the TPM shall return TPM_RC_VALUE.

NOTE 8 The TPM will require TPM_SU_CLEAR when no shutdown was performed or after Shutdown(CLEAR).

NOTE 9 If *startupType* is neither TPM_SU_STATE nor TPM_SU_CLEAR, then the unmarshaling code returns TPM_RC_VALUE.

9.4 TPM2_Shutdown

9.4.1 General Description

This command is used to prepare the TPM for a power cycle. The *shutdownType* parameter indicates how the subsequent TPM2_Startup() will be processed.

For a *shutdownType* of any type, the volatile portion of Clock is saved to NV memory and the orderly shutdown indication is SET. NV Indexes with the TPMA_NV_ORDERLY attribute will be updated.

For a *shutdownType* of TPM_SU_STATE, the following additional items are saved:

- tracking information for saved session contexts;
- the session context counter;
- PCR that are designated as being preserved by TPM2_Shutdown(TPM_SU_STATE);
- the PCR Update Counter;
- flags associated with supporting the TPMA_NV_WRITESTCLEAR and TPMA_NV_READSTCLEAR attributes;
- the counter value and authPolicy for each ACT; and

  NOTE If a counter has not been updated since the last TPM2_Startup(), then the saved value will be one half of the current counter value.

- the command audit digest and count.

The following items shall not be saved and will not be in TPM memory after the next TPM2_Startup:

- TPM-memory-resident session contexts;
- TPM-memory-resident transient objects; or
- TPM-memory-resident hash contexts created by TPM2_HashSequenceStart().

Some values may be either derived from other values or saved to NV memory.

This command saves TPM state but does not change the state other than the internal indication that the context has been saved. The TPM shall continue to accept commands. If a subsequent command changes TPM state saved by this command, then the effect of this command is nullified. The TPM MAY nullify this command for any subsequent command rather than check whether the command changed state saved by this command. If this command is nullified. and if no TPM2_Shutdown() occurs before the next TPM2_Startup(), then the next TPM2_Startup() shall be TPM2_Startup(CLEAR).

10 Testing

10.1 Introduction

Compliance to standards for hardware security modules may require that the TPM test its functions before the results that depend on those functions may be returned. The TPM may perform operations using testable functions before those functions have been tested as long as the TPM returns no value that depends on the correctness of the testable function.

EXAMPLE TPM2_PCR_Extend() may be executed before the hash algorithms have been tested. However, until the hash algorithms have been tested, the contents of a PCR may not be used in any command if that command may result in a value being returned to the TPM user. This means that TPM2_PCR_Read() or TPM2_PolicyPCR() could not complete until the hashes have been checked but other TPM2_PCR_Extend() commands may be executed even though the operation uses previous PCR values.

If a command is received that requires return of a value that depends on untested functions, the TPM shall test the required functions before completing the command.

Once the TPM has received TPM2_SelfTest() and before completion of all tests, the TPM is required to return TPM_RC_TESTING for any command that uses a function that requires a test.

If a self-test fails at any time, the TPM will enter Failure mode. While in Failure mode, the TPM will return TPM_RC_FAILURE for any command other than TPM2_GetTestResult() and TPM2_GetCapability(). The TPM will remain in Failure mode until the next _TPM_Init.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

10.2 TPM2_SelfTest

10.2.1 General Description

This command causes the TPM to perform a test of its capabilities. If the *fullTest* is YES, the TPM will test all functions. If *fullTest* = NO, the TPM will only test those functions that have not previously been tested.

If any tests are required, the TPM shall either

- return TPM_RC_TESTING and begin self-test of the required functions, or

  NOTE 1 If *fullTest* is NO, and all functions have been tested, the TPM shall return TPM_RC_SUCCESS.

- perform the tests and return the test result when complete. On failure, the TPM shall return TPM_RC_FAILURE.

If the TPM uses option a), the TPM shall return TPM_RC_TESTING for any command that requires use of a testable function, even if the functions required for completion of the command have already been tested.

NOTE 2 This command may cause the TPM to continue processing after it has returned the response. So that software can be notified of the completion of the testing, the interface may include controls that would allow the TPM to generate an interrupt when the “background” processing is complete. This would be in addition to the interrupt that may be available for signaling normal command completion. It is not necessary that there be two interrupts, but the interface should provide a way to indicate the nature of the interrupt (normal command or deferred command).

NOTE 3 The PC Client platform specific TPM, in response to *fullTest* YES, will not return TPM_RC_TESTING. It will block until all tests are complete.

10.3 TPM2_IncrementalSelfTest

10.3.1 General Description

This command causes the TPM to perform a test of the selected algorithms.

NOTE 1 The *toTest* list indicates the algorithms that software would like the TPM to test in anticipation of future use. This allows tests to be done so that a future commands will not be delayed due to testing.

The implementation may treat algorithms on the *toTest* list as either 'test each completely' or 'test this combination.'

EXAMPLE If the *toTest* list includes AES and CTR mode, it may be interpreted as a request to test only AES in CTR mode. Alternatively, it may be interpreted as a request to test AES in all modes and CTR mode for all symmetric algorithms.

If *toTest* contains an algorithm that has already been tested, it will not be tested again.

NOTE 2 The only way to force retesting of an algorithm is with TPM2_SelfTest(*fullTest* = YES).

The TPM will return in *toDoList* a list of algorithms that are yet to be tested. This list is not the list of algorithms that are scheduled to be tested but the algorithms/functions that have not been tested. Only the algorithms on the *toTest* list are scheduled to be tested by this command.

NOTE 3 An algorithm remains on the *toDoList* while any part of it remains untested.

EXAMPLE A symmetric algorithm remains untested until it is tested with all its modes.

Making *toTest* an empty list allows the determination of the algorithms that remain untested without triggering any testing.

If *toTest* is not an empty list, the TPM shall return TPM_RC_SUCCESS for this command and then return TPM_RC_TESTING for any subsequent command (including TPM2_IncrementalSelfTest()) until the requested testing is complete.

NOTE 4 If *toDoList* is empty, then no additional tests are required and TPM_RC_TESTING will not be returned in subsequent commands and no additional delay will occur in a command due to testing.

NOTE 5 If none of the algorithms listed in *toTest* is in the *toDoList*, then no tests will be performed.

NOTE 6 The TPM cannot return TPM_RC_TESTING for the first call to this command even when testing is not complete, because response parameters can only returned with the TPM_RC_SUCCESS return code.

If all the parameters in this command are valid, the TPM returns TPM_RC_SUCCESS and the *toDoList* (which may be empty).

NOTE 7 An implementation may perform all requested tests before returning TPM_RC_SUCCESS, or it may return TPM_RC_SUCCESS for this command and then return TPM_RC_TESTING for all subsequence commands (including TPM2_IncrementatSelfTest()) until the requested tests are complete.

10.4 TPM2_GetTestResult

10.4.1 General Description

This command returns manufacturer-specific information regarding the results of a self-test and an indication of the test status.

If TPM2_SelfTest() has not been executed and a testable function has not been tested, *testResult* will be TPM_RC_NEEDS_TEST. If TPM2_SelfTest() has been received and the tests are not complete, *testResult* will be TPM_RC_TESTING.

If testing of all functions is complete without functional failures, *testResult* will be TPM_RC_SUCCESS. If any test failed, *testResult* will be TPM_RC_FAILURE.

This command will operate when the TPM is in Failure mode so that software can determine the test status of the TPM and so that diagnostic information can be obtained for use in failure analysis. If the TPM is in Failure mode, then *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

NOTE The reference implementation may return a 32-bit value *s_failFunction*. This simply gives a unique value to each of the possible places where a failure could occur. It is not intended to provide a pointer to the function. __func__ is a pointer to a character string but the failure mode code can only return 32-bit values. It is expected that the manufacturer can disambiguate this value if a customer's TPM goes into failure mode.

10.4.3 Detailed Actions

```
1   #include "Tpm.h"
2   #include "GetTestResult_fp.h"
3   #if CC_GetTestResult  // Conditional expansion of this file
```

In the reference implementation, this function is only reachable if the TPM is not in failure mode meaning that all tests that have been run have completed successfully. There is not test data and the test result is TPM_RC_SUCCESS.

```
4   TPM_RC
5   TPM2_GetTestResult(
6       GetTestResult_Out   *out            // OUT: output parameter list
7       )
8   {
9   // Command Output
10
11      // Call incremental self test function in crypt module
12      out->testResult = CryptGetTestResult(&out->outData);
13
14      return TPM_RC_SUCCESS;
15  }
16  #endif // CC_GetTestResult
```

11 Session Commands

11.1 TPM2_StartAuthSession

11.1.1 General Description

This command is used to start an authorization session using alternative methods of establishing the session key (*sessionKey*). The session key is then used to derive values used for authorization and for encrypting parameters.

This command allows injection of a secret into the TPM using either asymmetric or symmetric encryption. The type of *tpmKey* determines how the value in *encryptedSalt* is encrypted. The decrypted secret value is used to compute the *sessionKey*.

NOTE 1 If *tpmKey* Is TPM_RH_NULL, then *encryptedSalt* is required to be an Empty Buffer.

The label value of "SECRET" (see "Terms and Definitions" in TPM 2.0 Part 1) is used in the recovery of the secret value.

The TPM generates the *sessionKey* from the recovered secret value.

No authorization is required for *tpmKey* or *bind*.

NOTE 2 The justification for using *tpmKey* without providing authorization is that the result of using the key is not available to the caller, except indirectly through the *sessionKey*. This does not represent a point of attack on the value of the key. If the caller attempts to use the session without knowing the *sessionKey* value, it is an authorization failure that will trigger the dictionary attack logic.

The entity referenced with the *bind* parameter contributes an authorization value to the *sessionKey* generation process.

If both *tpmKey* and *bind* are TPM_RH_NULL, then *sessionKey* is set to the Empty Buffer. If *tpmKey* is not TPM_RH_NULL, then *encryptedSalt* is used in the computation of *sessionKey*. If *bind* is not TPM_RH_NULL, the *authValue* of *bind* is used in the *sessionKey* computation.

If *symmetric* specifies a block cipher, then TPM_ALG_CFB is the only allowed value for the *mode* field in the *symmetric* parameter (TPM_RC_MODE).

This command starts an authorization session and returns the session handle along with an initial *nonceTPM* in the response.

If the TPM does not have a free slot for an authorization session, it shall return TPM_RC_SESSION_HANDLES.

If the TPM implements a "gap" scheme for assigning *contextID* values, then the TPM shall return TPM_RC_CONTEXT_GAP if creating the session would prevent recycling of old saved contexts (See "Context Management" in TPM 2.0 Part 1).

If *tpmKey* is not TPM_ALG_NULL then *encryptedSalt* shall be a TPM2B_ENCRYPTED_SECRET of the proper type for *tpmKey*. The TPM shall return TPM_RC_HANDLE if the sensitive portion of *tpmKey* is not loaded. The TPM shall return TPM_RC_VALUE if:

a) *tpmKey* references an RSA key and
   1) the size of *encryptedSalt* is not the same as the size of the public modulus of *tpmKey*,
   2) *encryptedSalt* has a value that is greater than the public modulus of *tpmKey*,
   3) *encryptedSalt* is not a properly encoded OAEP value, or
   4) the decrypted *salt* value is larger than the size of the digest produced by the *nameAlg* of *tpmKey*; or

 Copyright © TCG 2006-2020

NOTE 3 The asymScheme of the key object is ignored in this case and TPM_ALG_OAEP is used, even if asymScheme is set to TPM_ALG_NULL.

b) *tpmKey* references an ECC key and *encryptedSalt*

1) does not contain a TPMS_ECC_POINT or

2) is not a point on the curve of *tpmKey*;

NOTE 4 When ECC is used, the point multiply process produces a value (Z) that is used in a KDF to produce the final secret value. The size of the secret value is an input parameter to the KDF and the result will be set to be the size of the digest produced by the *nameAlg* of *tpmKey*.

The TPM shall return TPM_RC_KEY if *tpmkey* does not reference an asymmetric key. The TPM shall return TPM_RC_VALUE if the scheme of the key is not TPM_ALG_OAEP or TPM_ALG_NULL. The TPM shall return TPM_RC_ATTRIBUTES if tpmKey does not have the *decrypt* attribute SET.

NOTE While TPM_RC_VALUE is preferred, TPM_RC_SCHEME is acceptable.

If *bind* references a transient object, then the TPM shall return TPM_RC_HANDLE if the sensitive portion of the object is not loaded.

For all session types, this command will cause initialization of the *sessionKey* and may establish binding between the session and an object (the *bind* object). If *sessionType* is TPM_SE_POLICY or TPM_SE_TRIAL, the additional session initialization is:

- set *policySession→policyDigest* to a Zero Digest (the digest size for *policySession→policyDigest* is the size of the digest produced by *authHash*);
- authorization may be given at any locality;
- authorization may apply to any command code;
- authorization may apply to any command parameters or handles;
- the authorization has no time limit;
- an authValue is not needed when the authorization is used;
- the session is not bound;
- the session is not an audit session; and
- the time at which the policy session was created is recorded.

Additionally, if *sessionType* is TPM_SE_TRIAL, the session will not be usable for authorization but can be used to compute the *authPolicy* for an object.

NOTE 5 Although this command changes the session allocation information in the TPM, it does not invalidate a saved context. That is, TPM2_Shutdown() is not required after this command in order to re-establish the orderly state of the TPM. This is because the created context will occupy an available slot in the TPM and sessions in the TPM do not survive any TPM2_Startup(). However, if a created session is context saved, the orderly state does change.

The TPM shall return TPM_RC_SIZE if *nonceCaller* is less than 16 octets or is greater than the size of the digest produced by *authHash*.

11.2 TPM2_PolicyRestart

11.2.1 General Description

This command allows a policy authorization session to be returned to its initial state. This command is used after the TPM returns TPM_RC_PCR_CHANGED. That response code indicates that a policy will fail because the PCR have changed after TPM2_PolicyPCR() was executed. Restarting the session allows the authorizations to be replayed because the session restarts with the same *nonceTPM*. If the PCR are valid for the policy, the policy may then succeed.

This command does not reset the policy ID or the policy start time.

12 Object Commands

12.1 TPM2_Create

12.1.1 General Description

This command is used to create an object that can be loaded into a TPM using TPM2_Load(). If the command completes successfully, the TPM will create the new object and return the object's creation data (*creationData*), its public area (*outPublic*), and its encrypted sensitive area (*outPrivate*). Preservation of the returned data is the responsibility of the caller. The object will need to be loaded (TPM2_Load()) before it may be used. The only difference between the *inPublic* TPMT_PUBLIC template and the *outPublic* TPMT_PUBLIC object is in the *unique* field.

NOTE 1 This command may require temporary use of a transient resource, even though the object does not remain loaded after the command. See Part 1 Transient Resources.

TPM2B_PUBLIC template (*inPublic*) contains all of the fields necessary to define the properties of the new object. The setting for these fields is defined in "Public Area Template" in Part 1 of this specification and in "TPMA_OBJECT" in Part 2 of this specification. The size of the *unique* field shall not be checked for consistency with the other object parameters.

NOTE 2 For interoperability, the *unique* field should not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail. A size of zero is recommended. After unmarshaling, the TPM does not use the input *unique* field. It is, however, used in TPM2_CreatePrimary() and TPM2_CreateLoaded.

EXAMPLE 1 A TPM_ALG_RSA object with a *keyBits* of 2048 in the object's parameters should have a *unique* field that is no larger than 256 bytes.

EXAMPLE 2 TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object should have a *unique* field that is no larger than the digest produced by the object's *nameAlg*.

The *parentHandle* parameter shall reference a loaded decryption key that has both the public and sensitive area loaded.

When defining the object, the caller provides a template structure for the object in a TPM2B_PUBLIC structure (*inPublic*), an initial value for the object's *authValue (inSensitive.userAuth),* and, if the object is a symmetric object, an optional initial data value (*inSensitive.data*). The TPM shall validate the consistency of the attributes of *inPublic* according to the Creation rules in "TPMA_OBJECT" in TPM 2.0 Part 2.

The *inSensitive* parameter may be encrypted using parameter encryption.

The methods in this clause are used by both TPM2_Create() and TPM2_CreatePrimary(). When a value is indicated as being TPM-generated, the value is filled in by bits from the RNG if the command is TPM2_Create() and with values from **KDFa**() if the command is TPM2_CreatePrimary(). The parameters of each creation value are specified in TPM 2.0 Part 1.

The *sensitiveDataOrigin* attribute of *inPublic* shall be SET if *inSensitive.data* is an Empty Buffer and CLEAR if *inSensitive.data* is not an Empty Buffer or the TPM shall return TPM_RC_ATTRIBUTES.

If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

The TPM will create new data for the sensitive area and compute a TPMT_PUBLIC.*unique* from the sensitive area based on the object type:

a) For a symmetric key:

   1) If *inSensitive*.sensitive.*data* is the Empty Buffer, a TPM-generated key value is placed in the new object's TPMT_SENSITIVE.*sensitive.sym*. The size of the key will be determined by *inPublic.publicArea.parameters*.

 Copyright © TCG 2006-2020

2) If *inSensitive*.sensitive.*data* is not the Empty Buffer, the TPM will validate that the size of *inSensitive.data* is no larger than the key size indicated in the *inPublic template* (TPM_RC_SIZE) and copy the *inSensitive.data* to TPMT_SENSITIVE.*sensitive.sym* of the new object.

3) A TPM-generated obfuscation value is placed in TPMT_SENSITIVE.*sensitive.seedValue*. The size of the obfuscation value is the size of the digest produced by the nameAlg in *inPublic*. This value prevents the public *unique* value from leaking information about the *sensitive* area.

4) The TPMT_PUBLIC.*unique.sym* value for the new object is then generated, as shown in equation (1) below, by hashing the key and obfuscation values in the TPMT_SENSITIVE with the *nameAlg* of the object.

$$unique := \mathbf{H}_{nameAlg}(sensitive.seedValue.buffer \mid\mid sensitive.any.buffer) \quad (1)$$

b) If the Object is an asymmetric key:

1) If *inSensitive.sensitive.data* is not the Empty Buffer, then the TPM shall return TPM_RC_VALUE.

2) A TPM-generated private key value is created with the size determined by the parameters of inPublic.publicArea.parameters.

3) If the key is a Storage Key, a TPM-generated TPMT_SENSITIVE.*seedValue* value is created; otherwise, TPMT_SENSITIVE.*seedValue.size* is set to zero.

NOTE 3 An Object that is not a storage key has no child Objects to encrypt, so it does not need a symmetric key.

4) The public *unique* value is computed from the private key according to the methods of the key type.

5) If the key is an ECC key and the scheme required by the curveID is not the same as *scheme* in the public area of the template, then the TPM shall return TPM_RC_SCHEME.

6) If the key is an ECC key and the KDF required by the curveID is not the same as *kdf* in the pubic area of the template, then the TPM shall return TPM_RC_KDF.

NOTE 4 There is currently no command in which the caller may specify the KDF to be used with an ECC decryption key. Since there is no use for this capability, the reference implementation requires that the *kdf* in the template be set to TPM_ALG_NULL or TPM_RC_KDF is returned.

c) If the Object is a *keyedHash* object:

1) If *inSensitive.sensitive.data* is an Empty Buffer, and both *sign* and *decrypt* are CLEAR in the attributes of *inPublic*, the TPM shall return TPM_RC_ATTRIBUTES. This would be a data object with no data.

NOTE 5 Revisions 134 and earlier reference code did not check the error case of *sensitiveDataOrigin* SET and an Empty Buffer. Thus, some TPM implementations may also not have included this error check.

2) If *sign* and *decrypt* are both CLEAR, or if *sign* and *decrypt* are both SET and the *scheme* in the public area of the template is not TPM_ALG_NULL, the TPM shall return TPM_RC_SCHEME.

NOTE 6 Revisions 138 and earlier did not enforce this error case.

3) If *inSensitive.sensitive.data* is not an Empty Buffer, the TPM will copy the *inSensitive.sensitive.data* to TPMT_SENSITIVE.*sensitive.bits* of the new object.

NOTE 7 The size of inSensitive.sensitive.data is limited to be no larger than MAX_SYM_DATA.

4) If *inSensitive.sensitive.data* is an Empty Buffer, a TPM-generated key value that is the size of the digest produced by the *nameAlg* in *inPublic* is placed in TPMT_SENSITIVE.*sensitive.bits*.

 Copyright © TCG 2006-2020

5) A TPM-generated obfuscation value that is the size of the digest produced by the *nameAlg* of *inPublic* is placed in TPMT_SENSITIVE.*seedValue*.

6) The TPMT_PUBLIC.*unique.keyedHash* value for the new object is then generated, as shown in equation (1) above, by hashing the key and obfuscation values in the TPMT_SENSITIVE with the *nameAlg* of the object.

For TPM2_Load(), the TPM will apply normal symmetric protections to the created TPMT_SENSITIVE to create *outPublic*.

NOTE 8 The encryption key is derived from the symmetric seed in the sensitive area of the parent.

In addition to *outPublic* and *outPrivate*, the TPM will build a TPMS_CREATION_DATA structure for the object. TPMS_CREATION_DATA.*outsideInfo* is set to *outsideInfo*. This structure is returned in *creationData*. Additionally, the digest of this structure is returned in *creationHash*, and, finally, a TPMT_TK_CREATION is created so that the association between the creation data and the object may be validated by TPM2_CertifyCreation().

If the object being created is a Storage Key and *fixedParent* is SET in the attributes of *inPublic*, then the symmetric algorithms and parameters of *inPublic* are required to match those of the parent. The algorithms that must match are *inPublic.nameAlg*, and the values in *inPublic.parameters* that select the symmetric scheme. If *inPublic.nameAlg* does not match, the TPM shall return TPM_RC_HASH.If the symmetric scheme of the key does not match, the parent, the TPM shall return TPM_RC_SYMMETRIC. The TPM shall not use different response code to differentiate between mismatches of the components of *inPublic.parameters*. However, after this verification, when using the scheme to encrypt child objects, the TPM ignores the symmetric mode and uses TPM_ALG_CFB.

NOTE 9 The symmetric scheme is a TPMT_SYM_DEF_OBJECT. In a symmetric block ciphier, it is at *inPublic.parameters.symDetail.sym* and in an asymmetric object is at *inPublic.parameters.asymDetail.symmetric*.

NOTE 10 Prior to revision 01.34, the parent asymmetric algorithms were also checked for *fixedParent* storage keys.

```

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*sensitiveDataOrigin* is CLEAR when *sensitive.data* is an Empty Buffer, or is SET when *sensitive.data* is not empty; *fixedTPM*, *fixedParent*, or *encryptedDuplication* attributes are inconsistent between themselves or with those of the parent object; inconsistent *restricted*, *decrypt* and *sign* attributes; attempt to inject sensitive data for an asymmetric key;
TPM_RC_HASH	non-duplicable storage key and its parent have different name algorithm
TPM_RC_KDF	incorrect KDF specified for decrypting keyed hash object
TPM_RC_KEY	invalid key size values in an asymmetric key public area or a provided symmetric key has a value that is not allowed
TPM_RC_KEY_SIZE	key size in public area for symmetric key differs from the size in the sensitive creation area; may also be returned if the TPM does not allow the key size to be used for a Storage Key
TPM_RC_OBJECT_MEMORY	a free slot is not available as scratch memory for object creation
TPM_RC_RANGE	the exponent value of an RSA key is not supported.
TPM_RC_SCHEME	inconsistent attributes *decrypt*, *sign*, or *restricted* and key's scheme ID; or hash algorithm is inconsistent with the scheme ID for keyed hash object
TPM_RC_SIZE	size of public *authPolicy* or sensitive *authValue* does not match digest size of the name algorithm sensitive data size for the keyed hash object is larger than is allowed for the scheme
TPM_RC_SYMMETRIC	a storage key with no symmetric algorithm specified; or non-storage key with symmetric algorithm different from TPM_ALG_NULL
TPM_RC_TYPE	unknown object type; *parentHandle* does not reference a restricted decryption key in the storage hierarchy with both public and sensitive portion loaded
TPM_RC_VALUE	exponent is not prime or could not find a prime using the provided parameters for an RSA key; unsupported name algorithm for an ECC key
TPM_RC_OBJECT_MEMORY	there is no free slot for the object

71  }
72  #endif // CC_Create
```

12.2 TPM2_Load

12.2.1 General Description

This command is used to load objects into the TPM. This command is used when both a TPM2B_PUBLIC and TPM2B_PRIVATE are to be loaded. If only a TPM2B_PUBLIC is to be loaded, the TPM2_LoadExternal command is used.

NOTE 1 Loading an object is not the same as restoring a saved object context.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2 of this specification. If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

Objects loaded using this command will have a Name. The Name is the concatenation of *nameAlg* and the digest of the public area using the *nameAlg.*

NOTE 2 *nameAlg* is a parameter in the public area of the inPublic structure.

If *inPrivate.size* is zero, the load will fail.

After *inPrivate.buffer* is decrypted using the symmetric key of the parent, the integrity value shall be checked before the sensitive area is used, or unmarshaled.

NOTE 3 Checking the integrity before the data is used prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the digest of the TPMT_PUBLIC structure in *inPublic*).

NOTE 4 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithms specified in the *nameAlg* of the object.

NOTE 5 The returned handle is associated with the object until the object is flushed (TPM2_FlushContext) or until the next TPM2_Startup.

For all objects, the size of the key in the sensitive area shall be consistent with the key size indicated in the public area or the TPM shall return TPM_RC_KEY_SIZE.

Before use, a loaded object shall be checked to validate that the public and sensitive portions are properly linked, cryptographically. Use of an object includes use in any policy command. If the parts of the object are not properly linked, the TPM shall return TPM_RC_BINDING. If a weak symmetric key is in the sensitive portion, the TPM shall return TPM_RC_KEY.

EXAMPLE 1 For a symmetric object, the unique value in the public area shall be the digest of the sensitive key and the obfuscation value.

EXAMPLE 2 For a two-prime RSA key, the remainder when dividing the public modulus by the private key shall be zero and it shall be possible to form a private exponent from the two prime factors of the public modulus.

EXAMPLE 3 For an ECC key, the public point shall be f(x) where x is the private key.

12.3 TPM2_LoadExternal

12.3.1 General Description

This command is used to load an object that is not a Protected Object into the TPM. The command allows loading of a public area or both a public and sensitive area.

NOTE 1 Typical use for loading a public area is to allow the TPM to validate an asymmetric signature. Typical use for loading both a public and sensitive area is to allow the TPM to be used as a crypto accelerator.

Load of a public external object area allows the object to be associated with a hierarchy so that the correct algorithms may be used when creating tickets. The *hierarchy* parameter provides this association. If the public and sensitive portions of the object are loaded, *hierarchy* is required to be TPM_RH_NULL.

NOTE 2 If both the public and private portions of an object are loaded, the object is not allowed to appear to be part of a hierarchy.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2. In particular, *fixedTPM*, *fixedParent*, and *restricted* shall be CLEAR if *inPrivate* is not the Empty Buffer.

NOTE 3 The duplication status of a public key needs to be able to be the same as the full key which may be resident on a different TPM. If both the public and private parts of the key are loaded, then it is not possible for the key to be either *fixedTPM* or *fixedParent*, since, its private area would not be available in the clear to load.

Objects loaded using this command will have a Name. The Name is the *nameAlg* of the object concatenated with the digest of the public area using the *nameAlg.* The Qualified Name for the object will be the same as its Name. The TPM will validate that the *authPolicy* is either the size of the digest produced by *nameAlg* or the Empty Buffer.

NOTE 4 If *nameAlg* is TPM_ALG_NULL, then the Name is the Empty Buffer. When the authorization value for an object with no Name is computed, no Name value is included in the HMAC. To ensure that these unnamed entities are not substituted, they should have an *authValue* that is statistically unique.

NOTE 5 The digest size for TPM_ALG_NULL is zero.

If the *nameAlg* is TPM_ALG_NULL, the TPM shall not verify the cryptographic binding between the public and sensitive areas, but the TPM will validate that the size of the key in the sensitive area is consistent with the size indicated in the public area. If it is not, the TPM shall return TPM_RC_KEY_SIZE.

NOTE 6 For an ECC object, the TPM will verify that the public key is on the curve of the key before the public area is used.

If *nameAlg* is not TPM_ALG_NULL, then the same consistency checks between *inPublic* and *inPrivate* are made as for TPM2_Load().

NOTE 7 Consistency checks are necessary because an object with a Name needs to have the public and sensitive portions cryptographically bound so that an attacker cannot mix pubic and sensitive areas.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the TPMT_PUBLIC structure in *inPublic*).

NOTE 8 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithm specified in the *nameAlg* of the object.

 Copyright © TCG 2006-2020

The *hierarchy* parameter associates the external object with a hierarchy. External objects are flushed when their associated hierarchy is disabled. If *hierarchy* is TPM_RH_NULL, the object is part of no hierarchy, and there is no implicit flush.

If *hierarchy* is TPM_RH_NULL or *nameAlg* is TPM_ALG_NULL, a ticket produced using the object shall be a NULL Ticket.

EXAMPLE If a key is loaded with hierarchy set to TPM_RH_NULL, then TPM2_VerifySignature() will produce a NULL Ticket of the required type.

External objects are Temporary Objects. The saved external object contexts shall be invalidated at the next TPM Reset.

If a weak symmetric key is in the sensitive area, the TPM shall return TPM_RC_KEY.

For an RSA key, the private exponent is computed using the two prime factors of the public modulus. One of the primes is P, and the second prime (Q) is found by dividing the public modulus by P. A TPM may return an error (TPM_RC_BINDING) if the bit size of P and Q are not the same."

12.4 TPM2_ReadPublic

12.4.1 General Description

This command allows access to the public area of a loaded object.

Use of the *objectHandle* does not require authorization.

NOTE Since the caller is not likely to know the public area of the object associated with *objectHandle*, it would not be possible to include the Name associated with *objectHandle* in the *cpHash* computation.

If *objectHandle* references a sequence object, the TPM shall return TPM_RC_SEQUENCE.

12.5 TPM2_ActivateCredential

12.5.1 General Description

This command enables the association of a credential with an object in a way that ensures that the TPM has validated the parameters of the credentialed object.

If both the public and private portions of *activateHandle* and *keyHandle* are not loaded, then the TPM shall return TPM_RC_AUTH_UNAVAILABLE.

If *keyHandle* is not a Storage Key, then the TPM shall return TPM_RC_TYPE.

Authorization for *activateHandle* requires the ADMIN role.

The key associated with *keyHandle* is used to recover a seed from secret, which is the encrypted seed. The Name of the object associated with activateHandle and the recovered seed are used in a KDF to recover the symmetric key. The recovered seed (but not the Name) is used in a KDF to recover the HMAC key.

The HMAC is used to validate that the *credentialBlob* is associated with *activateHandle* and that the data in *credentialBlob* has not been modified. The linkage to the object associated with activateHandle is achieved by including the Name in the HMAC calculation.

If the integrity checks succeed, *credentialBlob* is decrypted and returned as *certInfo*.

NOTE The output *certInfo* parameter is an application defined value. It is typically a symmetric key or seed that is used to decrypt a certificate. See the TPM2_MakeCredential *credential* input parameter.

12.6 TPM2_MakeCredential

12.6.1 General Description

This command allows the TPM to perform the actions required of a Certificate Authority (CA) in creating a TPM2B_ID_OBJECT containing an activation credential.

NOTE The input *credential* parameter is an application defined value. It is typically a symmetric key or seed that is used to encrypt a certificate. See the TPM2_ActivateCredential *certInfo* output parameter.

The TPM will produce a TPM2B_ID_OBJECT according to the methods in “Credential Protection” in TPM 2.0 Part 1.

The loaded public area referenced by *handle* is required to be the public area of a Storage key, otherwise, the credential cannot be properly sealed.

This command does not use any TPM secrets nor does it require authorization. It is a convenience function, using the TPM to perform cryptographic calculations that could be done externally.

12.7 TPM2_Unseal

12.7.1 General Description

This command returns the data in a loaded Sealed Data Object.

NOTE 1 A random, TPM-generated, Sealed Data Object may be created by the TPM with TPM2_Create() or TPM2_CreatePrimary() using the template for a Sealed Data Object.

NOTE 2 TPM 1.2 hard coded PCR authorization. TPM 2.0 PCR authorization requires a policy.

The returned value may be encrypted using authorization session encryption.

If either *restricted*, *decrypt,* or *sign* is SET in the attributes of *itemHandle,* then the TPM shall return TPM_RC_ATTRIBUTES. If the *type* of *itemHandle* is not TPM_ALG_KEYEDHASH, then the TPM shall return TPM_RC_TYPE.

12.8 TPM2_ObjectChangeAuth

12.8.1 General Description

This command is used to change the authorization secret for a TPM-resident object.

If successful, a new private area for the TPM-resident object associated with *objectHandle* is returned, which includes the new authorization value.

This command does not change the authorization of the TPM-resident object on which it operates. Therefore, the old authValue (of the TPM-resident object) is used when generating the response HMAC key if required.

NOTE 1 The returned *outPrivate* will need to be loaded before the new authorization will apply.

NOTE 2 The TPM-resident object may be persistent and changing the authorization value of the persistent object could prevent other users from accessing the object. This is why this command does not change the TPM-resident object.

EXAMPLE If a persistent key is being used as a Storage Root Key and the authorization of the key is a well-known value so that the key can be used generally, then changing the authorization value in the persistent key would deny access to other users.

This command may not be used to change the authorization value for an NV Index or a Primary Object.

NOTE 3 If an NV Index is to have a new authorization, it is done with TPM2_NV_ChangeAuth().

NOTE 4 If a Primary Object is to have a new authorization, it needs to be recreated (TPM2_CreatePrimary()).

12.9 TPM2_CreateLoaded

12.9.1 General Description

This command creates an object and loads it in the TPM. This command allows creation of any type of object (Primary, Ordinary, or Derived) depending on the type of *parentHandle.* If *parentHandle* references a Primary Seed, then a Primary Object is created; if *parentHandle* references a Storage Parent, then an Ordinary Object is created; and if *parentHandle* references a Derivation Parent, then a Derived Object is generated.

The input validation is the same as for TPM2_Create() and TPM2_CreatePrimary() with one exception: when *parentHandle* references a Derivation Parent, then *sensitiveDataOrigin* in *inPublic* is required to be CLEAR.

Note 1 In the general descriptions of TPM2_Create() and TPM2_CreatePrimary() the validations refer to a TPMT_PUBLIC structure that is in *inPublic.* For TPM2_CreateLoaded(), *inPublic* is a TPM2B_TEMPLATE that may contain a TPMT_PUBLIC that is used for object creation. For object derivation, the *unique* field can contain a *label* and *context* that are used in the derivation process. To allow both the TPMT_PUBLIC and the derivation variation, a TPM2B_TEMPLATE is used. When referring to the checks in TPM2_Create() and TPM2_CreatePrimary(), TPM2B_TEMPLATE should be assumed to contain a TPMT_PUBLIC.

If *parentHandle* references a Derivation Parent, then the TPM may return TPM_RC_TYPE if the key type to be generated is an RSA key.

If *parentHandle* references a Derivation Parent or a Primary Seed, then *outPrivate* will be an Empty Buffer.

NOTE 2 Returning outPrivate would imply that the returned primary or derived object can be loaded and it cannot. It can only be re-derived.

A primary key cannot be loaded is because loading a key is a way to attack the protections of a key (e.g. using DPA). A saved context for a primary object is protected. The TPM will go into failure mode if the integrity of a saved context is good but the fingerprint doesn't decrypt. It is not possible to have these protections on loaded objects because this would be a simple way for an attacker to put the TPM into failure mode Saved contexts are assumed to be under control of the driver but loaded objects are not.

If all objects were derived from their parents then, load could not be used as an attack. However, that would preclude importation of objects and key hierarchies.

NOTE 3 Unlike TPM2_Create() and TPM2_CreatePrimary(), this command does not return creation data. If creation data is needed, then TPM2_Create() or TPM2_CreatePrimary() should be used.

13 Duplication Commands

13.1 TPM2_Duplicate

13.1.1 General Description

This command duplicates a loaded object so that it may be used in a different hierarchy. The new parent key for the duplicate may be on the same or different TPM or TPM_RH_NULL. Only the public area of *newParentHandle* is required to be loaded.

NOTE 1 Since the new parent may only be extant on a different TPM, it is likely that the new parent's sensitive area could not be loaded in the TPM from which *objectHandle* is being duplicated.

If *encryptedDuplication* is SET in the object being duplicated, then the TPM shall return TPM_RC_SYMMETRIC if *symmetricAlg.algorithm* is TPM_ALG_NULL or TPM_RC_HIERARCHY if *newParentHandle* is TPM_RH_NULL.

The authorization for this command shall be with a policy session.

If *fixedParent* of *objectHandle→attributes* is SET, the TPM shall return TPM_RC_ATTRIBUTES. If *objectHandle→nameAlg* is TPM_ALG_NULL, the TPM shall return TPM_RC_TYPE.

The *policySession→commandCode* parameter in the policy session is required to be TPM_CC_Duplicate to indicate that authorization for duplication has been provided. This indicates that the policy that is being used is a policy that is for duplication, and not a policy that would approve another use. That is, authority to use an object does not grant authority to duplicate the object.

The policy is likely to include cpHash in order to restrict where duplication can occur. If TPM2_PolicyCpHash() has been executed as part of the policy, the *policySession→cpHash* is compared to the cpHash of the command.

If TPM2_PolicyDuplicationSelect() has been executed as part of the policy, the *policySession→nameHash* is compared to

$$\mathbf{H}_{policyAlg}(objectHandle{\rightarrow}Name \mid\mid newParentHandle{\rightarrow}Name) \tag{2}$$

If the compared hashes are not the same, then the TPM shall return TPM_RC_POLICY_FAIL.

NOTE 2 It is allowed that policySesion→nameHash and policySession→cpHash share the same memory space.

NOTE 3 A duplication policy is not required to have either TPM2_PolicyDuplicationSelect() or TPM2_PolicyCpHash() as part of the policy. If neither is present, then the duplication policy may be satisfied with a policy that only contains TPM2_PolicyCommandCode(*code* = TPM_CC_Duplicate).

The TPM shall follow the process of encryption defined in the "Duplication" subclause of "Protected Storage Hierarchy" in TPM 2.0 Part 1.

13.1.2 Command and Response

Table 37 — TPM2_Duplicate Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Duplicate
TPMI_DH_OBJECT	@objectHandle	loaded object to duplicate Auth Index: 1 Auth Role: DUP
TPMI_DH_OBJECT+	newParentHandle	shall reference the public area of an asymmetric key Auth Index: None
TPM2B_DATA	encryptionKeyIn	optional symmetric encryption key The size for this key is set to zero when the TPM is to generate the key. This parameter may be encrypted.
TPMT_SYM_DEF_OBJECT+	symmetricAlg	definition for the symmetric algorithm to be used for the inner wrapper may be TPM_ALG_NULL if no inner wrapper is applied

Table 38 — TPM2_Duplicate Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_DATA	encryptionKeyOut	If the caller provided an encryption key or if *symmetricAlg* was TPM_ALG_NULL, then this will be the Empty Buffer; otherwise, it shall contain the TPM-generated, symmetric encryption key for the inner wrapper.
TPM2B_PRIVATE	duplicate	private area that may be encrypted by *encryptionKeyIn*; and may be doubly encrypted
TPM2B_ENCRYPTED_SECRET	outSymSeed	seed protected by the asymmetric algorithms of new parent (NP)

13.1.3 Detailed Actions

```
1  #include "Tpm.h"
2  #include "Duplicate_fp.h"
3  #if CC_Duplicate  // Conditional expansion of this file
4  #include "Object_spt_fp.h"
```

Error Returns	Meaning
TPM_RC_ATTRIBUTES	key to duplicate has *fixedParent* SET
TPM_RC_HASH	for an RSA key, the *nameAlg* digest size for the *newParent* is not compatible with the key size
TPM_RC_HIERARCHY	*encryptedDuplication* is SET and *newParentHandle* specifies Null Hierarchy
TPM_RC_KEY	*newParentHandle* references invalid ECC key (public point not on the curve)
TPM_RC_SIZE	input encryption key size does not match the size specified in symmetric algorithm
TPM_RC_SYMMETRIC	*encryptedDuplication* is SET but no symmetric algorithm is provided
TPM_RC_TYPE	*newParentHandle* is neither a storage key nor TPM_RH_NULL; or the object has a NULL *nameAlg*
TPM_RC_VALUE	for an RSA *newParent*, the sizes of the digest and the encryption key are too large to be OAEP encoded

13.2 TPM2_Rewrap

13.2.1 General Description

This command allows the TPM to serve in the role as a Duplication Authority. If proper authorization for use of the *oldParent* is provided, then an HMAC key and a symmetric key are recovered from *inSymSeed* and used to integrity check and decrypt *inDuplicate.* A new protection seed value is generated according to the methods appropriate for *newParent* and the blob is re-encrypted and a new integrity value is computed. The re-encrypted blob is returned in *outDuplicate* and the symmetric key returned in *outSymKey*.

In the rewrap process, L is “DUPLICATE” (see TPM 2.0 Part 1, *Terms and Definitions*).

If *inSymSeed* has a zero length, then *oldParent* is required to be TPM_RH_NULL and no decryption of *inDuplicate* takes place.

If *newParent* is TPM_RH_NULL, then no encryption is performed on *outDuplicate. outSymSeed* will have a zero length. See TPM 2.0 Part 2 *encryptedDuplication*.

```

13.3 TPM2_Import

13.3.1 General Description

This command allows an object to be encrypted using the symmetric encryption values of a Storage Key. After encryption, the object may be loaded and used in the new hierarchy. The imported object (*duplicate*) may be singly encrypted, multiply encrypted, or unencrypted.

If *fixedTPM* or *fixedParent* is SET in *objectPublic*, the TPM shall return TPM_RC_ATTRIBUTES.

If *encryptedDuplication* is SET in the object referenced by *parentHandle* and *encryptedDuplication* is CLEAR in *objectPublic,* the TPM may return TPM_RC_ATTRIBUTES.

If encryptedDuplication is SET in objectPublic, then *inSymSeed* and *encryptionKey* shall not be Empty buffers (TPM_RC_ATTRIBUTES). Recovery of the sensitive data of the object occurs in the TPM in a multi--step process in the following order:

a) If *inSymSeed* has a non-zero size:

   1) The asymmetric parameters and private key of *parentHandle* are used to recover the seed used in the creation of the HMAC key and encryption keys used to protect the duplication blob.

      NOTE 1 When recovering the seed from *inSymSeed*, *L* is "DUPLICATE".

   2) The integrity value in *duplicate.buffer.integrityOuter* is used to verify the integrity of the data blob, which is the remainder of *duplicate.buffer* (TPM_RC_INTEGRITY).

      NOTE 2 The data blob will contain a TPMT_SENSITIVE and may contain a TPM2B_DIGEST for the *innerIntegrity.*

   3) The symmetric key recovered in 1) is used to decrypt the data blob.

      NOTE 3 Checking the integrity before the data is used prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

b) If *encryptionKey* is not an Empty Buffer:

   1) Use *encryptionKey* to decrypt the inner blob.

   2) Use the TPM2B_DIGEST at the start of the inner blob to verify the integrity of the inner blob (TPM_RC_INTEGRITY).

c) Unmarshal the sensitive area

NOTE 4 It is not necessary to validate that the sensitive area data is cryptographically bound to the public area other than that the Name of the public area is included in the HMAC. However, if the binding is not validated by this command, the binding must be checked each time the object is loaded. For an object that is imported under a parent with *fixedTPM* SET, binding need only be checked at import. If the parent has *fixedTPM* CLEAR, then the binding needs to be checked each time the object is loaded, or before the TPM performs an operation for which the binding affects the outcome of the operation (for example, TPM2_PolicySigned() or TPM2_Certify()).

Similarly, if the new parent's *fixedTPM* is set, the *encryptedDuplication* state need only be checked at import.

If the new parent is not *fixedTPM*, then that object will be loadable on any TPM (including SW versions) on which the new parent exists. This means that, each time an object is loaded under a parent that is not *fixedTPM*, it is necessary to validate all of the properties of that object. If the parent is *fixedTPM*, then the new private blob is integrity protected by the TPM that "owns" the parent. So, it is sufficient to validate the object's properties (attribute and public-private binding) on import and not again.

If a weak symmetric key is being imported, the TPM shall return TPM_RC_KEY.

 Copyright © TCG 2006-2020

After integrity checks and decryption, the TPM will create a new symmetrically encrypted private area using the encryption key of the parent.

NOTE 5 The symmetric re-encryption is the normal integrity generation and symmetric encryption applied to a child object.

NOTE 6 Revision 01.16 of this specification required the ECC private key in *duplicate* to be padded.

13.3.2 Command and Response

Table 41 — TPM2_Import Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Import
TPMI_DH_OBJECT	@parentHandle	the handle of the new parent for the object Auth Index: 1 Auth Role: USER
TPM2B_DATA	encryptionKey	the optional symmetric encryption key used as the inner wrapper for *duplicate* If *symmetricAlg* is TPM_ALG_NULL, then this parameter shall be the Empty Buffer.
TPM2B_PUBLIC	objectPublic	the public area of the object to be imported This is provided so that the integrity value for *duplicate* and the object attributes can be checked. NOTE Even if the integrity value of the object is not checked on input, the object Name is required to create the integrity value for the imported object.
TPM2B_PRIVATE	duplicate	the symmetrically encrypted duplicate object that may contain an inner symmetric wrapper
TPM2B_ENCRYPTED_SECRET	inSymSeed	the seed for the symmetric key and HMAC key *inSymSeed* is encrypted/encoded using the algorithms of *newParent*.
TPMT_SYM_DEF_OBJECT+	symmetricAlg	definition for the symmetric algorithm to use for the inner wrapper If this algorithm is TPM_ALG_NULL, no inner wrapper is present and *encryptionKey* shall be the Empty Buffer.

Table 42 — TPM2_Import Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_PRIVATE	outPrivate	the sensitive area encrypted with the symmetric key of *parentHandle*

13.3.3 Detailed Actions

```
1 #include "Tpm.h"
2 #include "Import_fp.h"
3 #if CC_Import  // Conditional expansion of this file
4 #include "Object_spt_fp.h"
```

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*FixedTPM* and *fixedParent* of *objectPublic* are not both CLEAR; or *inSymSeed* is nonempty and *parentHandle* does not reference a decryption key; or *objectPublic* and *parentHandle* have incompatible or inconsistent attributes; or *encrytpedDuplication* is SET in *objectPublic* but the inner or outer wrapper is missing. Note that if the TPM provides parameter values, the parameter number will indicate *symmetricKey* (missing inner wrapper) or *inSymSeed* (missing outer wrapper)
TPM_RC_BINDING	*duplicate* and *objectPublic* are not cryptographically bound
TPM_RC_ECC_POINT	*inSymSeed* is nonempty and ECC point in *inSymSeed* is not on the curve
TPM_RC_HASH	*objectPublic* does not have a valid *nameAlg*
TPM_RC_INSUFFICIENT	*inSymSeed* is nonempty and failed to retrieve ECC point from the secret; or unmarshaling sensitive value from *duplicate* failed the result of *inSymSeed* decryption
TPM_RC_INTEGRITY	*duplicate* integrity is broken
TPM_RC_KDF	*objectPublic* representing decrypting keyed hash object specifies invalid KDF
TPM_RC_KEY	inconsistent parameters of *objectPublic*; or *inSymSeed* is nonempty and *parentHandle* does not reference a key of supported type; or invalid key size in *objectPublic* representing an asymmetric key
TPM_RC_NO_RESULT	*inSymSeed* is nonempty and multiplication resulted in ECC point at infinity
TPM_RC_OBJECT_MEMORY	no available object slot
TPM_RC_SCHEME	inconsistent attributes *decrypt*, *sign*, *restricted* and key's scheme ID in *objectPublic*; or hash algorithm is inconsistent with the scheme ID for keyed hash object
TPM_RC_SIZE	*authPolicy* size does not match digest size of the name algorithm in *objectPublic*; or *symmetricAlg* and *encryptionKey* have different sizes; or *inSymSeed* is nonempty and it size is not consistent with the type of *parentHandle*; or unmarshaling sensitive value from *duplicate* failed
TPM_RC_SYMMETRIC	*objectPublic* is either a storage key with no symmetric algorithm or a non-storage key with symmetric algorithm different from TPM_ALG_NULL
TPM_RC_TYPE	unsupported type of *objectPublic*; or *parentHandle* is not a storage key; or only the public portion of *parentHandle* is loaded; or *objectPublic* and *duplicate* are of different types
TPM_RC_VALUE	nonempty *inSymSeed* and its numeric value is greater than the modulus of the key referenced by *parentHandle* or *inSymSeed* is larger than the size of the digest produced by the name algorithm of the symmetric key referenced by *parentHandle*

14 Asymmetric Primitives

14.1 Introduction

The commands in this clause provide low-level primitives for access to the asymmetric algorithms implemented in the TPM. Many of these commands are only allowed if the asymmetric key is an unrestricted key.

14.2 TPM2_RSA_Encrypt

14.2.1 General Description

This command performs RSA encryption using the indicated padding scheme according to IETF RFC 8017. If the *scheme* of *keyHandle* is TPM_ALG_NULL, then the caller may use *inScheme* to specify the padding scheme. If *scheme* of keyHandle is not TPM_ALG_NULL, then *inScheme* shall either be TPM_ALG_NULL or be the same as *scheme* (TPM_RC_SCHEME).

The key referenced by *keyHandle* is required to be an RSA key (TPM_RC_KEY).

The three types of allowed padding are:

1) TPM_ALG_OAEP – Data is OAEP padded as described in 7.1 of IETF RFC 8017 (PKCS#1). The only supported mask generation is MGF1.

2) TPM_ALG_RSAES – Data is padded as described in 7.2 of IETF RFC 8017 (PKCS#1).

3) TPM_ALG_NULL – Data is not padded by the TPM and the TPM will treat *message* as an unsigned integer and perform a modular exponentiation of *message* using the public exponent of the key referenced by *keyHandle*. This scheme is only used if both the *scheme* in the key referenced by *keyHandle* is TPM_ALG_NULL, and the *inScheme* parameter of the command is TPM_ALG_NULL. The input value cannot be larger than the public modulus of the key referenced by *keyHandle*.

Table 43 — Padding Scheme Selection

keyHandle→scheme	***inScheme***	**padding scheme used**
TPM_ALG_NULL	TPM_ALG_NULL	none
	TPM_ALG_RSAES	RSAES
	TPM_ALG_OAEP	OAEP
TPM_ALG_RSAES	TPM_ALG_NULL	RSAES
	TPM_ALG_RSAES	RSAES
	TPM_ALG_OAEP	error (TPM_RC_SCHEME)
TPM_ALG_OAEP	TPM_ALG_NULL	OAEP
	TPM_ALG_RSAES	error (TPM_RC_SCHEME)
	TPM_ALG_OAEP	OAEP

After padding, the data is RSAEP encrypted according to 5.1.1 of IETF RFC 8017 (PKCS#1).

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

NOTE 1 Because only the public portion of the key needs to be loaded for this command, the caller can manipulate the attributes of the key in any way desired. As a result, the TPM shall not check the consistency of the attributes. The only property checking is that the key is an RSA key and that the padding scheme is supported.

 Copyright © TCG 2006-2020

The *message* parameter is limited in size by the padding scheme according to the following table:

Table 44 — Message Size Limits Based on Padding

Scheme	Maximum Message Length (*mLen*) in Octets	Comments
TPM_ALG_OAEP	$mLen \leq k - 2hLen - 2$	
TPM_ALG_RSAES	$mLen \leq k - 11$	
TPM_ALG_NULL	$mLen \leq k$	The numeric value of the message must be less than the numeric value of the public modulus (n).
NOTES 1) $k :=$ the number of byes in the public modulus 2) $hLen :=$ the number of octets in the digest produced by the hash algorithm used in the process		

The *label* parameter is optional. If provided (*label.size* != 0) then the TPM shall return TPM_RC_VALUE if the last octet in *label* is not zero. The terminating octet of zero is included in the *label* used in the padding scheme.

NOTE 2 If the scheme does not use a label, the TPM will still verify that label is properly formatted if label is present.

NOTE 3 Specifications before version 1.54 stated that *label* is truncated after the first zero octet. Applications should not include embedded zero bytes for compatibility.

The function returns padded and encrypted value *outData*.

The *message* parameter in the command may be encrypted using parameter encryption.

NOTE 4 Only the public area of *keyHandle* is required to be loaded. A public key may be loaded with any desired scheme. If the scheme is to be changed, a different public area must be loaded.

14.3 TPM2_RSA_Decrypt

14.3.1 General Description

This command performs RSA decryption using the indicated padding scheme according to IETF RFC 8017 ((PKCS#1).

The scheme selection for this command is the same as for TPM2_RSA_Encrypt() and is shown in Table 43.

The key referenced by *keyHandle* shall be an RSA key (TPM_RC_KEY) with *restricted* CLEAR and *decrypt* SET (TPM_RC_ATTRIBUTES).

This command uses the private key of *keyHandle* for this operation and authorization is required.

The TPM will perform a modular exponentiation of ciphertext using the private exponent associated with *keyHandle* (this is described in IETF RFC 8017 (PKCS#1), clause 5.1.2). It will then validate the padding according to the selected scheme. If the padding checks fail, TPM_RC_VALUE is returned. Otherwise, the data is returned with the padding removed. If no padding is used, the returned value is an unsigned integer value that is the result of the modular exponentiation of *cipherText* using the private exponent of *keyHandle*. The returned value may include leading octets zeros so that it is the same size as the public modulus. For the other padding schemes, the returned value will be smaller than the public modulus but will contain all the data remaining after padding is removed and this may include leading zeros if the original encrypted value contained leading zeros.

If a label is used in the padding process of the scheme during encryption, the *label* parameter is required to be present in the decryption process and *label* is required to be the same in both cases. If label is not the same, the decrypt operation is very likely to fail ((TPM_RC_VALUE). If *label* is present (*label.size* != 0), it shall be a byte stream whose last byte is zero or the TPM will return TPM_RC_VALUE.

NOTE 1 The size of *label* includes the terminating null.

The *message* parameter in the response may be encrypted using parameter encryption.

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

If the scheme does not require a label, the value in *label* is not used but the size of the label field is checked for consistency with the indicated data type (TPM2B_DATA). That is, the field may not be larger than allowed for a TPM2B_DATA.

14.4 TPM2_ECDH_KeyGen

14.4.1 General Description

This command uses the TPM to generate an ephemeral key pair (d_e, Q_e where $Q_e \coloneqq [d_e]G$). It uses the private ephemeral key and a loaded public key (Q_S) to compute the shared secret value ($P \coloneqq [hd_e]Q_S$).

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY). The sensitive portion of this key need not be loaded.

The curve parameters of the loaded ECC key are used to generate the ephemeral key.

NOTE This function is the equivalent of encrypting data to another object's public key. The *seed* value is used in a KDF to generate a symmetric key and that key is used to encrypt the data. Once the data is encrypted and the symmetric key discarded, only the object with the private portion of the *keyHandle* will be able to decrypt it.

The *zPoint* in the response may be encrypted using parameter encryption.

47     return result;
48 }
49 #endif // CC_ECDH_KeyGen
```

14.5 TPM2_ECDH_ZGen

14.5.1 General Description

This command uses the TPM to recover the *Z* value from a public point (Q_B) and a private key (d_s). It will perform the multiplication of the provided *inPoint* (Q_B) with the private key (d_s) and return the coordinates of the resultant point ($Z = (x_Z, y_Z) \coloneqq [hd_s]Q_B$; where h is the cofactor of the curve).

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY) with the *restricted* attribute CLEAR and the *decrypt* attribute SET (TPM_RC_ATTRIBUTES).

NOTE While TPM_RC_ATTRIBUTES is preferred, TPM_RC_KEY is acceptable.

The *scheme* of the key referenced by *keyHandle* is required to be either TPM_ALG_ECDH or TPM_ALG_NULL (TPM_RC_SCHEME).

inPoint is required to be on the curve of the key referenced by *keyHandle* (TPM_RC_ECC_POINT).

The parameters of the key referenced by *keyHandle* are used to perform the point multiplication.

14.6 TPM2_ECC_Parameters

14.6.1 General Description

This command returns the parameters of an ECC curve identified by its TCG-assigned *curveID*.

The value returned is the same as that from the TCG Algorithm Registry, but may not be the same size.

EXAMPLE The value 01 may be returned as 00000001.

14.7 TPM2_ZGen_2Phase

14.7.1 General Description

This command supports two-phase key exchange protocols. The command is used in combination with TPM2_EC_Ephemeral(). TPM2_EC_Ephemeral() generates an ephemeral key and returns the public point of that ephemeral key along with a numeric value that allows the TPM to regenerate the associated private key.

The input parameters for this command are a static public key (*inQsU*), an ephemeral key (*inQeU*) from party B, and the *commitCounter* returned by TPM2_EC_Ephemeral(). The TPM uses the counter value to regenerate the ephemeral private key ($d_{e,V}$) and the associated public key ($Q_{e,V}$). *keyA* provides the static ephemeral elements $d_{s,V}$ and $Q_{s,V}$. This provides the two pairs of ephemeral and static keys that are required for the schemes supported by this command.

The TPM will compute $Z\ or\ Z_s$ and Z_e according to the selected scheme. If the scheme is not a two-phase key exchange scheme or if the scheme is not supported, the TPM will return TPM_RC_SCHEME.

It is an error if *inQsB* or *inQeB* are not on the curve of *keyA* (TPM_RC_ECC_POINT).

The two-phase key schemes that were assigned an algorithm ID as of the time of the publication of this specification are TPM_ALG_ECDH, TPM_ALG_ECMQV, and TPM_ALG_SM2.

If this command is supported, then support for TPM_ALG_ECDH is required. Support for TPM_ALG_ECMQV or TPM_ALG_SM2 is optional.

NOTE 1 If SM2 is supported and this command is supported, then the implementation is required to support the key exchange protocol of SM2, part 3.

For TPM_ALG_ECDH *outZ1* will be Zs and *outZ2* will Ze as defined in 6.1.1.2 of SP800-56A.

NOTE 2 An unrestricted decryption key using ECDH may be used in either TPM2_ECDH_ZGen() or TPM2_ZGen_2Phase as the computation done with the private part of *keyA* is the same in both cases.

For TPM_ALG_ECMQV or TPM_ALG_SM2 *outZ1* will be Z and *outZ2* will be an Empty Point.

NOTE 3 An Empty Point has two Empty Buffers as coordinates meaning the minimum *size* value for *outZ2* will be four.

If the input scheme is TPM_ALG_ECDH, then *outZ1* will be Z_s and outZ2 will be Z_e. For schemes like MQV (including SM2), *outZ1* will contain the computed value and *outZ2* will be an Empty Point.

NOTE 4 The Z values returned by the TPM are a full point and not just an x-coordinate.

If a computation of either Z produces the point at infinity, then the corresponding Z value will be an Empty Point.

15 Symmetric Primitives

15.1 Introduction

The commands in this clause provide low-level primitives for access to the symmetric algorithms implemented in the TPM that operate on blocks of data. These include symmetric encryption and decryption as well as hash and HMAC. All of the commands in this group are stateless. That is, they have no persistent state that is retained in the TPM when the command is complete.

For hashing, HMAC, and Events that require large blocks of data with retained state, the sequence commands are provided (see clause 1).

Some of the symmetric encryption/decryption modes use an IV. When an IV is used, it may be an initiation value or a chained value from a previous stage. The chaining for each mode is:

 Copyright © TCG 2006-2020

Table 57 — Symmetric Chaining Process

Mode	Chaining process
TPM_ALG_CTR	The TPM will increment the entire IV provided by the caller. The next count value will be returned to the caller as *ivOut*. This can be the input value to the next encrypt or decrypt operation. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. EXAMPLE 1 AES requires that *ivIn* be 128 bits (16 octets). *ivOut* will be the size of a cipher block and not the size of the last encrypted block. NOTE *ivOut* will be the value of the counter after the last block is encrypted. EXAMPLE 2 If *ivIn* were 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00_{16} and four data blocks were encrypted, *ivOut* will have a value of 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 04_{16}. All the bits of the IV are incremented as if it were an unsigned integer.
TPM_ALG_OFB	In Output Feedback (OFB), the output of the pseudo-random function (the block encryption algorithm) is XORed with a plaintext block to produce a ciphertext block. *ivOut* will be the value that was XORed with the last plaintext block. That value can be used as the *ivIn* for a next buffer. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *ivOut* will be the size of a cipher block and not the size of the last encrypted block.
TPM_ALG_CBC	For Cipher Block Chaining (CBC), a block of ciphertext is XORed with the next plaintext block and that block is encrypted. The encrypted block is then input to the encryption of the next block. The last ciphertext block then is used as an IV for the next buffer. Even though the last ciphertext block is evident in the encrypted data, it is also returned in *ivOut*. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *inData* is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of *inData* is not correct, the TPM shall return TPM_RC_SIZE.
TPM_ALG_CFB	Similar to CBC in that the last ciphertext block is an input to the encryption of the next block. *ivOut* will be the value that was XORed with the last plaintext block. That value can be used as the *ivIn* for a next buffer. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *ivOut* will be the size of a cipher block and not the size of the last encrypted block.
TPM_ALG_ECB	Electronic Codebook (ECB) has no chaining. Each block of plaintext is encrypted using the key. ECB does not support chaining and *ivIn* shall be the Empty Buffer. *ivOut* will be the Empty Buffer. *inData* is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of *inData* is not correct, the TPM shall return TPM_RC_SIZE.

15.2 TPM2_EncryptDecrypt

15.2.1 General Description

NOTE 1 This command is deprecated, and TPM2_EncryptDecrypt2() is preferred. This should be reflected in platform-specific specifications.

This command performs symmetric encryption or decryption using the symmetric key referenced by keyHandle and the selected mode.

keyHandle shall reference a symmetric cipher object (TPM_RC_KEY) with the *restricted* attribute CLEAR (TPM_RC_ATTRIBUTES).

If the *decrypt* parameter of the command is TRUE, then the *decrypt* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES). If the *decrypt* parameter of the command is FALSE, then the *sign* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES).

NOTE 2 A key may have both *decrypt* and *sign* SET.

If the mode of the key is not TPM_ALG_NULL, then that is the only mode that can be used with the key and the caller is required to set *mode* either to TPM_ALG_NULL or to the same mode as the key (TPM_RC_MODE). If the mode of the key is TPM_ALG_NULL, then the caller may set *mode* to any valid symmetric encryption/decryption mode but may not select TPM_ALG_NULL (TPM_RC_MODE).

If the TPM allows this command to be canceled before completion, then the TPM may produce incremental results and return TPM_RC_SUCCESS rather than TPM_RC_CANCELED. In such case, *outData* may be less than *inData*.

NOTE 3 If all the data is encrypted/decrypted, the size of outData will be the same as inData.

15.4 TPM2_Hash

15.4.1 General Description

This command performs a hash operation on a data buffer and returns the results.

NOTE If the data buffer to be hashed is larger than will fit into the TPM's input buffer, then the sequence hash commands will need to be used.

If the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign.

If the digest is not safe to sign, then the TPM will return a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

15.5 TPM2_HMAC

15.5.1 General Description

This command performs an HMAC on the supplied data using the indicated hash algorithm.

NOTE 1 A TPM may implement either TPM2_HMAC() or TPM2_MAC() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC(), but a TPM that supports TPM2_HMAC() will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then hashAlg is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see hash selection matrix in

Table 72).

NOTE 3 A key may only have both sign and decrypt SET if the key is unrestricted. When both sign and decrypt are set, there is no default scheme for the key and the hash algorithm must be specified.

15.6 TPM2_MAC

15.6.1 General Description

This command performs an HMAC or a block cipher MAC on the supplied data using the indicated algorithm.

NOTE 1 A TPM may implement either TPM2_HMAC() or TPM2_MAC() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC() but a TPM that supports TPM2_HMAC () will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is neither TPM_ALG_KEYEDHASH nor TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme or mode of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE).

If the default scheme of an HMAC key is TPM_ALG_NULL, then *inScheme* is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see algorithm selection matrix in

Table 75).

If the default mode of a symmetric cipher key is TPM_ALG_NULL, then *inScheme* is required to be a valid block cipher mode for authentication and not TPM_ALG_NULL (TPM_RC_VALUE)

NOTE 3 A key may only have both sign and decrypt SET if the key is unrestricted. When both sign and decrypt are set, there is no default scheme for the key and *inScheme* may not be TPM_ALG_NULL.

NOTE 4 TPM2_MAC() was added in revision 01.43.

16 Random Number Generator

16.1 TPM2_GetRandom

16.1.1 General Description

This command returns the next *bytesRequested* octets from the random number generator (RNG).

NOTE 1 It is recommended that a TPM implement the RNG in a manner that would allow it to return RNG octets such that, as long as the value of *bytesRequested* is not greater than the maximum digest size, the frequency of *bytesRequested* being more than the number of octets available is an infrequent occurrence.

If *bytesRequested* is more than will fit into a TPM2B_DIGEST on the TPM, no error is returned but the TPM will only return as much data as will fit into a TPM2B_DIGEST buffer for the TPM.

NOTE 2 TPM2B_DIGEST is large enough to hold the largest digest that may be produced by the TPM. Because that digest size changes according to the implemented hashes, the maximum amount of data returned by this command is TPM implementation-dependent.

17 Hash/HMAC/Event Sequences

17.1 Introduction

All of the commands in this group are to support sequences for which an intermediate state must be maintained. For a description of sequences, see "Hash, MAC, and Event Sequences" in TPM 2.0 Part 1.

A TPM may implement either TPM2_HMAC_Start() or TPM2_MAC_Start() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC_Start() but a TPM that supports TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

17.2 TPM2_HMAC_Start

17.2.1 General Description

This command starts an HMAC sequence. The TPM will create and initialize an HMAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then hashAlg is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 72 — Hash Selection Matrix

handle→restricted **(key's restricted attribute)**	***handle→scheme*** **(hash algorithm from key's *scheme*)**	***hashAlg***	**hash used**
CLEAR (unrestricted)	TPM_ALG_NULL[1]	TPM_ALG_NULL	error[1] (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash	*hashAlg*
CLEAR	valid hash	TPM_ALG_NULL or same as *handle→scheme*	*handle→scheme*
CLEAR	valid hash	valid hash	error (TPM_RC_VALUE) if *hashAlg* != *handle->scheme*
SET (restricted)	don't care	don't care	TPM_RC_ATTRIBUTES

NOTES:
1) A hash algorithm is required for the HMAC.

NOTE 1 A TPM may implement either TPM2_HMAC_Start() or TPM2_MAC_Start() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC_Start(), but a TPM that supports TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

17.3 TPM2_MAC_Start

17.3.1 General Description

This command starts a MAC sequence. The TPM will create and initialize a MAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH or TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then *inScheme*is required to be a valid hash or symmetric MAC scheme and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 75 — Algorithm Selection Matrix

handle→restricted **(key's restricted attribute)**	***handle→scheme*** **(algorithm from key's *scheme*)**	***inScheme***	**algorithm used**
CLEAR (unrestricted)	TPM_ALG_NULL(1)	TPM_ALG_NULL	error(1) (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash or symmetric MAC	*inScheme*
CLEAR	not TPM_ALG_NULL	TPM_ALG_NULL or same as *handle→scheme*	*handle→scheme*
CLEAR	not TPM_ALG_NULL	not TPM_AGL_NULL	error (TPM_RC_VALUE) if*inScheme*!= *handle->scheme*
SET (restricted)	don't care	don't care	TPM_RC_ATTRIBUTES

NOTES:
1) A hash algorithm is required for the HMAC.
2) hashAlg shall be TPM_ALG_NULL for handle referencing a CMAC key.

NOTE 3 For a TPM_ALG_SYMCIPHER key, the symmetric block cipher algorithm is part of the key definition.

NOTE 4 TPM2_MAC_Start() was added in revision 01.43.

17.4 TPM2_HashSequenceStart

17.4.1 General Description

This command starts a hash or an Event Sequence. If *hashAlg* is an implemented hash, then a hash sequence is started. If *hashAlg* is TPM_ALG_NULL, then an Event Sequence is started. If *hashAlg* is neither an implemented algorithm nor TPM_ALG_NULL, then the TPM shall return TPM_RC_HASH.

Depending on *hashAlg*, the TPM will create and initialize a Hash Sequence context or an Event Sequence context. Additionally, it will assign a handle to the context and set the *authValue* of the context to the value in *auth*. A sequence context for an Event (*hashAlg* = TPM_ALG_NULL) contains a hash context for each of the PCR banks implemented on the TPM.

17.5 TPM2_SequenceUpdate

17.5.1 General Description

This command is used to add data to a hash or HMAC sequence. The amount of data in buffer may be any size up to the limits of the TPM.

NOTE 1 In all TPM, a *buffer* size of 1,024 octets is allowed.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If the command does not return TPM_RC_SUCCESS, the state of the sequence is unmodified.

If the sequence is intended to produce a digest that will be signed by a restricted signing key, then the first block of data shall contain sizeof(TPM_GENERATED) octets and the first octets shall not be TPM_GENERATED_VALUE.

NOTE 2 This requirement allows the TPM to validate that the first block is safe to sign without having to accumulate octets over multiple calls.

17.6 TPM2_SequenceComplete

17.6.1 General Description

This command adds the last part of data, if any, to a hash/HMAC sequence and returns the result.

NOTE 1 This command is not used to complete an Event Sequence. TPM2_EventSequenceComplete() is used for that purpose.

For a hash sequence, if the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign.

If the *digest* is not safe to sign, then *validation* will be a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

NOTE 2 Regardless of the contents of the first octets of the hashed message, if the first buffer sent to the TPM had fewer than sizeof(TPM_GENERATED) octets, then the TPM will operate as if *digest* is not safe to sign.

NOTE 3 The ticket is only required for a signing operation that uses a restricted signing key. It is always returned, but can be ignored if not needed.

If *sequenceHandle* references an Event Sequence, then the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

17.7 TPM2_EventSequenceComplete

17.7.1 General Description

This command adds the last part of data, if any, to an Event Sequence and returns the result in a digest list. If *pcrHandle* references a PCR and not TPM_RH_NULL, then the returned digest list is processed in the same manner as the digest list input parameter to TPM2_PCR_Extend(). That is, if a bank contains a PCR associated with *pcrHandle,* it is extended with the associated digest value from the list.

If *sequenceHandle* references a hash or HMAC sequence, the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

NOTE: Unlike TPM2_PCR_Event(), a digest is always returned for each implemented hash algorithm. There is no option to only return digests for which *pcrHandle* is allocated.

18 Attestation Commands

18.1 Introduction

The attestation commands cause the TPM to sign an internally generated data structure. The contents of the data structure vary according to the command.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

All signing commands include a parameter (typically *inScheme*) for the caller to specify a scheme to be used for the signing operation. This scheme will be applied only if the scheme of the key is TPM_ALG_NULL or the key handle is TPM_RH_NULL. If the scheme for *signHandle* is not TPM_ALG_NULL, then *inScheme.scheme* shall be TPM_ALG_NULL or the same as *scheme* in the public area of the key. If the scheme for *signHandle* is TPM_ALG_NULL or the key handle is TPM_RH_NULL, then *inScheme* will be used for the signing operation and may not be TPM_ALG_NULL. The TPM shall return TPM_RC_SCHEME to indicate that the scheme is not appropriate.

For a signing key that is not restricted, the caller may specify the scheme to be used as long as the scheme is compatible with the family of the key (for example, TPM_ALG_RSAPSS cannot be selected for an ECC key). If the caller sets *scheme* to TPM_ALG_NULL, then the default scheme of the key is used. For a restricted signing key, the key's scheme cannot be TPM_ALG_NULL and cannot be overridden.

If the handle for the signing key (*signHandle*) is TPM_RH_NULL, then all of the actions of the command are performed and the attestation block is "signed" with the NULL Signature.

NOTE 1 This mechanism is provided so that additional commands are not required to access the data that might be in an attestation structure.

NOTE 2 When *signHandle* is TPM_RH_NULL, *scheme* is still required to be a valid signing scheme (may be TPM_ALG_NULL), but the scheme will have no effect on the format of the signature. It will always be the NULL Signature.

TPM2_NV_Certify() is an attestation command that is documented in 1. The remaining attestation commands are collected in the remainder of this clause.

Each of the attestation structures contains a TPMS_CLOCK_INFO structure and a firmware version number. These values may be considered privacy-sensitive, because they would aid in the correlation of attestations by different keys. To provide improved privacy, the *resetCount*, *restartCount*, and *firmwareVersion* numbers are obfuscated when the signing key is not in the Endorsement or Platform hierarchies.

The obfuscation value is computed by:

$$obfuscation \coloneqq \mathbf{KDFa}(signHandle{\rightarrow}nameAlg, shProof, \text{“OBFUSCATE”}, signHandle{\rightarrow}QN, 0, 128) \quad (3)$$

Of the returned 128 bits, 64 bits are added to the *versionNumber* field of the attestation structure; 32 bits are added to the *clockInfo.resetCount* and 32 bits are added to the *clockInfo.restartCount*. The order in which the bits are added is implementation-dependent.

NOTE 3 The obfuscation value for each signing key will be unique to that key in a specific location. That is, each version of a duplicated signing key will have a different obfuscation value.

When the signing key is TPM_RH_NULL, the data structure is produced but not signed; and the values in the signed data structure are obfuscated. When computing the obfuscation value for TPM_RH_NULL, the hash used for context integrity is used.

NOTE 4 The QN for TPM_RH_NULL is TPM_RH_NULL.

If the signing scheme of *signHandle* is an anonymous scheme, then the attestation blocks will not contain the Qualified Name of the *signHandle*.

 Copyright © TCG 2006-2020

Each of the attestation structures allows the caller to provide some qualifying data (*qualifyingData*). For most signing schemes, this value will be placed in the TPMS_ATTEST.*extraData* parameter that is then hashed and signed. However, for some schemes such as ECDAA, the *qualifyingData* is used in a different manner (for details, see “ECDAA” in TPM 2.0 Part 1).

18.2 TPM2_Certify

18.2.1 General Description

The purpose of this command is to prove that an object with a specific Name is loaded in the TPM. By certifying that the object is loaded, the TPM warrants that a public area with a given Name is self-consistent and associated with a valid sensitive area. If a relying party has a public area that has the same Name as a Name certified with this command, then the values in that public area are correct.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a policySession→*commandCode* set to TPM_CC_Certify. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

The object may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary(). An object that only has its public area loaded cannot be certified.

NOTE 2 The restriction occurs because the Name is used to identify the object being certified. If the TPM has not validated that the public area is associated with a matched sensitive area, then the public area may not represent a valid object and cannot be certified.

The certification includes the Name and Qualified Name of the certified object as well as the Name and the Qualified Name of the certifying object.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

18.3 TPM2_CertifyCreation

18.3.1 General Description

This command is used to prove the association between an object and its creation data. The TPM will validate that the ticket was produced by the TPM and that the ticket validates the association between a loaded public area and the provided hash of the creation data (*creationHash*).

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The TPM will create a test ticket using the Name associated with *objectHandle* and *creationHash* as:

$$\mathbf{HMAC}(proof, (\mathrm{TPM_ST_CREATION} \mathbin{||} objectHandle{\rightarrow}Name \mathbin{||} creationHash)) \tag{4}$$

This ticket is then compared to creation ticket. If the tickets are not the same, the TPM shall return TPM_RC_TICKET.

If the ticket is valid, then the TPM will create a TPMS_ATTEST structure and place *creationHash* of the command in the *creationHash* field of the structure. The Name associated with *objectHandle* will be included in the attestation data that is then signed using the key associated with *signHandle*.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

objectHandle may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary().

18.4 TPM2_Quote

18.4.1 General Description

This command is used to quote PCR values.

The TPM will hash the list of PCR selected by *PCRselect* using the hash algorithm in the selected signing scheme. If the selected signing scheme or the scheme hash algorithm is TPM_ALG_NULL, then the TPM shall return TPM_RC_SCHEME.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The digest is computed as the hash of the concatenation of all of the digest values of the selected PCR.

The concatenation of PCR is described in TPM 2.0 Part 1, *Selecting Multiple PCR.*

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

NOTE 3 A TPM may optionally return TPM_RC_SCHEME if *signHandle* is TPM_RH_NULL.

NOTE 4 Unlike TPM 1.2, TPM2_Quote does not return the PCR values. See Part 1, “Attesting to PCR” for a discussion of this issue.

18.5 TPM2_GetSessionAuditDigest

18.5.1 General Description

This command returns a digital signature of the audit session digest.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

If *sessionHandle* is not an audit session, the TPM shall return TPM_RC_TYPE.

NOTE 2 A session does not become an audit session until the successful completion of the command in which the session is first used as an audit session.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

If this command is audited, then the audit digest that is signed will not include the digest of this command because the audit digest is only updated when the command completes successfully.

This command does not cause the audit session to be closed and does not reset the digest value.

NOTE 3 If sessionHandle is used as an audit session for this command, the command is audited in the same manner as any other command.

NOTE 4 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

18.6 TPM2_GetCommandAuditDigest

18.6.1 General Description

This command returns the current value of the command audit digest, a digest of the commands being audited, and the audit hash algorithm. These values are placed in an attestation structure and signed with the key referenced by *signHandle*.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

When this command completes successfully, and *signHandle* is not TPM_RH_NULL, the audit digest is cleared. If signHandle is TPM_RH_NULL, *signature* is the Empty Buffer and the audit digest is not cleared.

NOTE 2 The way that the TPM tracks that the digest is clear is vendor-dependent. The reference implementation resets the size of the digest to zero.

If this command is being audited, then the signed digest produced by the command will not include the command. At the end of this command, the audit digest will be extended with *cpHash* and the *rpHash* of the command, which would change the command audit digest signed by the next invocation of this command.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

18.7 TPM2_GetTime

18.7.1 General Description

This command returns the current values of *Time* and *Clock*.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The values of *Clock*, *resetCount* and *restartCount* appear in two places in *timeInfo*: once in TPMS_ATTEST.*clockInfo* and again in TPMS_ATTEST.*attested.time.clockInfo.* The firmware version number also appears in two places (TPMS_ATTEST.*firmwareVersion* and TPMS_ATTEST.*attested.time.firmwareVersion*). If *signHandle* is in the endorsement or platform hierarchies, both copies of the data will be the same. However, if *signHandle* is in the storage hierarchy or is TPM_RH_NULL, the values in TPMS_ATTEST.*clockInfo* and TPMS_ATTEST.*firmwareVersion* are obfuscated but the values in TPMS_ATTEST.*attested.time* are not.

NOTE 2 The purpose of this duplication is to allow an entity who is trusted by the privacy Administrator to correlate the obfuscated values with the clear-text values. This command requires Endorsement Authorization.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

```

18.8 TPM2_CertifyX509

18.8.1 General Description

The purpose of this command is to generate an X.509 certificate that proves an object with a specific public key and attributes is loaded in the TPM. In contrast to TPM2_Certify, which uses a TCG-defined data structure to convey attestation information, TPM2_CertifyX509 encodes the attestation information in

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

a DER-encoded X.509 certificate that is compliant with RFC5280 *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile.*

As described in RFC, an X.509 certificate contains a collection of data that is hashed and signed. The full signature is the combination of the *to be signed* (TBS) data, a description of the signature algorithm, and the signature over the TBS data. The elements of the TBS data structure are DER-encoded values. They are:

1) Version [0] – integer value of 2 indicating version 3
2) Certificate Serial Number – integer value
3) Signature Algorithm Identifier – values (usually a collection of OIDs) identifying the algorithm used for the signature
4) Issuer Name – X.501 type *Name* to identify the entity that has authorized the use of *signHandle* to create the certificate.
5) Validity – two time values indicating the period during which the certificate is valid
6) Subject Name – X.501 type *Name* that identifies the entity that authorized the use of *objectHandle*
7) Subject Public Key Info – the public key associated with *objectHandle*,
8) Extensions [3] – a set of values that "provide methods for associating additional attributes with users or public keys and for managing relationships between CAs."

NOTE 1: The numbers in square brackets (e.g., [0]) indicate application-specific tag values that are used to identify the type of the field.

NOTE 2: RFC 5280 describes two fields (issuerUniqueID and subjectUniqueID) but goes on to say: "CAs conforming to this profile MUST NOT generate certificates with unique identifiers." The TPM does not allow them to be present.

The caller provides a partial certificate (*partialCertificate*) parameter that contains four or five of the elements enumerated above in a DER encoded SEQUENCE. They are:

1) Signature Algorithm Identifier (optional)
2) Issuer (mandatory)
3) Validity (mandatory)
4) Subject Name (mandatory)
5) Extensions (mandatory)

The fields are required to be in the order in which they are listed above.

NOTE 3: The TPM determines if the Signature Algorithm Identifier element is present by counting the elements.

The optional Signature Algorithm Identifier may be provided by the caller. If it is not present, the TPM will generate the value based on the selected signing scheme. If the caller provides this value, then the TPM will use it in the completed TBS. The TPM will not validate that the provided values are compatible with the signing scheme. If the caller does not provide this field and the TPM does not have OID values for the signing scheme, then the TPM will return an error (TPM_RC_SCHEME).

NOTE 4: The TPM may implement signing schemes for which OIDs are not defined at the time the TPM was manufactured. Those schemes may still be used if the caller can provide the Signature Algorithm Identifier.

The Extensions element is required to contain a Key Usage extension. The TPM will extract the Key Usage values and verify that the attributes of *objectHandle* are consistent with the selected values (TPM_RC_ATTRIBUTES)(See Part 2, *TPMA_X509_KEY_USAGE*).

The Extensions element may contain a TPMA_OBJECT extension. If present, the TPM will extract the value and verify that the extension value exactly matches the TPMA_OBJECT of *objectKey* (TPM_RC_ATTRIBUTES). The element uses the TCG OID tcg-tpmaObject, 2.23.133.10.1.1.1. It is a SEQUENCE containing that OID and an OCTET STRING encapsulating a 4-byte BIT STRING holding the big endian TPMA_OBJECT.

signHandle is required to have the *sign* attribute SET (TPM_RC_KEY).

NOTE 5: See 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a policySession→*commandCode* set to TPM_CC_CertifyX509. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

If *objectHandle* does not have a sensitive area loaded, the TPM will return an error (TPM_RC_AUTH_UNAVAILABLE).

NOTE 6: The command requires that authorization be provided for use of *objectHandle.* An object that only has its *publicArea* loaded does not have an authorization value and the *authPolicy* has no meaning as the sensitive area is not present.

The TPM will create the Version, the Certificate Serial Number, the Subject Public Key Info, and, if not provided by the caller, the Signature Algorithm Identifier. These TPM-created values will be combined with the provided values to make a full TBSCerfificate structure (See RFC 5280, clause 4.1). The TPM will then sign the certificate using the selected signing scheme.

The TPM-created values will be returned in *addedToCertificate.* If the TPM creates the Signature Algorithm Identifier, it will be in *addedToCertificate* before the Subject Public Key Info. The TPM returns *tbsDigest* as a debugging aid.

NOTE 7: These returned fields allow the caller to unambiguously create a full RFC5280-defined TBSCertificate.

NOTE 8: This command was added in revision 01.53.

19 Ephemeral EC Keys

19.1 Introduction

The TPM generates keys that have different lifetimes. TPM keys in a hierarchy can be persistent for as long as the seed of the hierarchy is unchanged and these keys may be used multiple times. Other TPM-generated keys are only useful for a single operation. Some of these single-use keys are used in the command in which they are created. Examples of this use are TPM2_Duplicate() where an ephemeral key is created for a single pass key exchange with another TPM. However, there are other cases, such as anonymous attestation, where the protocol requires two passes where the public part of the ephemeral key is used outside of the TPM before the final command "consumes" the ephemeral key.

For these uses, TPM2_Commit() or TPM2_EC_Ephemeral() may be used to have the TPM create an ephemeral EC key and return the public part of the key for external use. Then in a subsequent command, the caller provides a reference to the ephemeral key so that the TPM can retrieve or recreate the associated private key.

When an ephemeral EC key is created, it is assigned a number and that number is returned to the caller as the identifier for the key. This number is not a handle. A handle is assigned to a key that may be context saved but these ephemeral EC keys may not be saved and do not have a full key context. When a subsequent command uses the ephemeral key, the caller provides the number of the ephemeral key. The TPM uses that number to either look up or recompute the associated private key. After the key is used, the TPM records the fact that the key has been used so that it cannot be used again.

As mentioned, the TPM can keep each assigned private ephemeral key in memory until it is used. However, this could consume a large amount of memory. To limit the memory size, the TPM is allowed to restrict the number of pending private keys – keys that have been allocated but not used.

NOTE The minimum number of ephemeral keys is determined by a platform specific specification

To further reduce the memory requirements for the ephemeral private keys, the TPM is allowed to use pseudo-random values for the ephemeral keys. Instead of keeping the full value of the key in memory, the TPM can use a counter as input to a KDF. Incrementing the counter will cause the TPM to generate a new pseudo-random value.

Using the counter to generate pseudo-random private ephemeral keys greatly simplifies tracking of key usage. When a counter value is used to create a key, a bit in an array may be set to indicate that the key use is pending. When the ephemeral key is consumed, the bit is cleared. This prevents the key from being used more than once.

Since the TPM is allowed to restrict the number of pending ephemeral keys, the array size can be limited. For example, a 128 bit array would allow 128 keys to be "pending".

The management of the array is described in greater detail in the *Split Operations* clause in Annex C of TPM 2.0 Part 1.

19.2 TPM2_Commit

19.2.1 General Description

TPM2_Commit() performs the first part of an ECC anonymous signing operation. The TPM will perform the point multiplications on the provided points and return intermediate signing values. The *signHandle* parameter shall refer to an ECC key and the signing scheme must be anonymous (TPM_RC_SCHEME).

NOTE 1 Currently, TPM_ALG_ECDAA is the only defined anonymous scheme.

NOTE 2 This command cannot be used with a sign+decrypt key because that type of key is required to have a scheme of TPM_ALG_NULL.

For this command, *p1*, *s2* and *y2* are optional parameters. If *s2* is an Empty Buffer, then the TPM shall return TPM_RC_SIZE if *y2* is not an Empty Buffer.

The algorithm is specified in the TPM 2.0 Part 1 Annex for ECC, TPM2_Commit().

19.2.2 Command and Response

Table 100 — TPM2_Commit Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Commit
TPMI_DH_OBJECT	@signHandle	handle of the key that will be used in the signing operation Auth Index: 1 Auth Role: USER
TPM2B_ECC_POINT	P1	a point (M) on the curve used by *signHandle*
TPM2B_SENSITIVE_DATA	s2	octet array used to derive x-coordinate of a base point
TPM2B_ECC_PARAMETER	y2	y coordinate of the point associated with *s2*

Table 101 — TPM2_Commit Response

Type	Name	Description
TPM_ST	tag	see 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_ECC_POINT	K	ECC point $K \coloneqq [d_s](x2, y2)$
TPM2B_ECC_POINT	L	ECC point $L \coloneqq [r](x2, y2)$
TPM2B_ECC_POINT	E	ECC point $E \coloneqq [r]P1$
UINT16	counter	least-significant 16 bits of *commitCount*

19.2.3 Detailed Actions

```
1  #include "Tpm.h"
2  #include "Commit_fp.h"
3  #if CC_Commit  // Conditional expansion of this file
```

Error Returns	Meaning
TPM_RC_ATTRIBUTES	*keyHandle* references a restricted key that is not a signing key
TPM_RC_ECC_POINT	either *P1* or the point derived from *s2* is not on the curve of *keyHandle*
TPM_RC_HASH	invalid name algorithm in *keyHandle*
TPM_RC_KEY	*keyHandle* does not reference an ECC key
TPM_RC_SCHEME	the scheme of *keyHandle* is not an anonymous scheme
TPM_RC_NO_RESULT	*K*, *L* or *E* was a point at infinity; or failed to generate r value
TPM_RC_SIZE	*s2* is empty but *y2* is not or *s2* provided but *y2* is not

19.3 TPM2_EC_Ephemeral

19.3.1 General Description

TPM2_EC_Ephemeral() creates an ephemeral key for use in a two-phase key exchange protocol.

The TPM will use the commit mechanism to assign an ephemeral key r and compute a public point $Q \coloneqq [r]G$ where G is the generator point associated with *curveID*.

20 Signing and Signature Verification

20.1 TPM2_VerifySignature

20.1.1 General Description

This command uses loaded keys to validate a signature on a message with the message digest passed to the TPM.

If the signature check succeeds, then the TPM will produce a TPMT_TK_VERIFIED. Otherwise, the TPM shall return TPM_RC_SIGNATURE.

If the key is in the NULL hierarchy, then *digest* in the ticket will be the Empty Buffer.

NOTE 1 A valid ticket may be used in subsequent commands to provide proof to the TPM that the TPM has validated the signature over the message using the key referenced by *keyHandle*.

If *keyHandle* references an asymmetric key, only the public portion of the key needs to be loaded. If *keyHandle* references a symmetric key, both the public and private portions need to be loaded.

NOTE 2 The sensitive area of the symmetric object is required to allow verification of the symmetric signature (the HMAC).

44     return TPM_RC_SUCCESS;
45 }
46 #endif // CC_VerifySignature
```

20.2 TPM2_Sign

20.2.1 General Description

This command causes the TPM to sign an externally provided hash with the specified symmetric or asymmetric signing key.

NOTE 1 If *keyhandle* references an unrestricted signing key, a digest can be signed using either this command or an HMAC command.

If *keyHandle* references a restricted signing key, then *validation* shall be provided, indicating that the TPM performed the hash of the data and *validation* shall indicate that hashed data did not start with TPM_GENERATED_VALUE.

NOTE 2 If the hashed data did start with TPM_GENERATED_VALUE, then the validation will be a NULL ticket.

The *x509sign* attribute of keyHandle may not be SET (TPM_RC_ATTRIBUTES).

If the scheme of *keyHandle* is not TPM_ALG_NULL, then *inScheme* shall either be the same scheme as *keyHandle* or TPM_ALG_NULL. If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY.

If the scheme of *keyHandle* is TPM_ALG_NULL, the TPM will sign using *inScheme*; otherwise, it will sign using the scheme of *keyHandle*.

NOTE 3 When the signing scheme uses a hash algorithm, the algorithm is defined in the qualifying data of the scheme. This is the same algorithm that is required to be used in producing *digest*. The size of *digest* must match that of the hash algorithm in the scheme.

If *inScheme* is not a valid signing scheme for the type of keyHandle (or TPM_ALG_NULL), then the TPM shall return TPM_RC_SCHEME.

If the scheme of *keyHandle* is an anonymous *scheme*, then *inScheme* shall have the same scheme algorithm as *keyHandle* and *inScheme* will contain a counter value that will be used in the signing process.

EXAMPLE For ECDAA, *inScheme.details.ecdaa.count* will contain the count value.

If *validation* is provided, then the hash algorithm used in computing the digest is required to be the hash algorithm specified in the scheme of *keyHandle* (TPM_RC_TICKET).

If the *validation* parameter is not the Empty Buffer*,* then it will be checked even if the key referenced by *keyHandle* is not a restricted signing key.

NOTE 4 If *keyHandle* is both a sign and decrypt key, *keyHandle* will have a scheme of TPM_ALG_NULL. If *validation* is provided, then it must be a NULL validation ticket or the ticket validation will fail.

21 Command Audit

21.1 Introduction

If a command has been selected for command audit, the command audit status will be updated when that command completes successfully. The digest is updated as:

$$commandAuditDigest_{new} \coloneqq \mathbf{H}_{auditAlg}(commandAuditDigest_{old} \mathbin{||} cpHash \mathbin{||} rpHash) \tag{5}$$

where

$\boldsymbol{H}_{auditAlg}$	hash function using the algorithm of the audit sequence
$commandAuditDigest$	accumulated digest
$cpHash$	the command parameter hash
$rpHash$	the response parameter hash

auditAlg, the hash algorithm, is set using TPM2_SetCommandCodeAuditStatus().

TPM2_Shutdown() cannot be audited but TPM2_Startup() can be audited. If the *cpHash* of the TPM2_Startup() is TPM_SU_STATE, that would indicate that a TPM2_Shutdown() had been successfully executed.

TPM2_SetCommandCodeAuditStatus() is always audited, except when it is used to change *auditAlg*.

If the TPM is in Failure mode, command audit is not functional.

 Copyright © TCG 2006-2020

21.2 TPM2_SetCommandCodeAuditStatus

21.2.1 General Description

This command may be used by the Privacy Administrator or platform to change the audit status of a command or to set the hash algorithm used for the audit digest, but not both at the same time.

If the *auditAlg* parameter is a supported hash algorithm and not the same as the current algorithm, then the TPM will check both *setList* and *clearList* are empty (zero length). If so, then the algorithm is changed, and the audit digest is cleared. If *auditAlg* is TPM_ALG_NULL or the same as the current algorithm, then the algorithm and audit digest are unchanged and the *setList* and *clearList* will be processed.

NOTE 1 Because the audit digest is cleared, the audit counter will increment the next time that an audited command is executed.

Use of TPM2_SetCommandCodeAuditStatus() to change the list of audited commands is an audited event. If TPM_CC_SetCommandCodeAuditStatus is in *clearList,* the fact that it is in *clearList* is ignored.

NOTE 2 Use of this command to change the audit hash algorithm is not audited and the digest is reset when the command completes. The change in the audit hash algorithm is the evidence that this command was used to change the algorithm.

The commands in *setList* indicate the commands to be added to the list of audited commands and the commands in *clearList* indicate the commands that will no longer be audited. It is not an error if a command in *setList* is already audited or is not implemented. It is not an error if a command in *clearList* is not currently being audited or is not implemented.

If a command code is in both *setList* and *clearList*, then it will not be audited (that is, *setList* shall be processed first).

22 Integrity Collection (PCR)

22.1 Introduction

In TPM 1.2, an Event was hashed using SHA-1 and then the 20-octet digest was extended to a PCR using TPM_Extend(). This specification allows the use of multiple PCR at a given Index, each using a different hash algorithm. Rather than require that the external software generate multiple hashes of the Event with each being extended to a different PCR, the Event data may be sent to the TPM for hashing. This ensures that the resulting digests will properly reflect the algorithms chosen for the PCR even if the calling software is unable to implement the hash algorithm.

NOTE 1 There is continued support for software hashing of events with TPM2_PCR_Extend().

To support recording of an Event that is larger than the TPM input buffer, the caller may use the command sequence described in clause 1.

Change to a PCR requires authorization. The authorization may be with either an authorization value or an authorization policy. The platform-specific specifications determine which PCR may be controlled by policy. All other PCR are controlled by authorization.

If a PCR may be associated with a policy, then the algorithm ID of that policy determines whether the policy is to be applied. If the algorithm ID is not TPM_ALG_NULL, then the policy digest associated with the PCR must match the *policySession→policyDigest* in a policy session. If the algorithm ID is TPM_ALG_NULL, then no policy is present and the authorization requires an EmptyAuth.

If a platform-specific specification indicates that PCR are grouped, then all the PCR in the group use the same authorization policy or authorization value.

pcrUpdateCounter counter will be incremented on the successful completion of any command that modifies (Extends or resets) a PCR unless the platform-specific specification explicitly excludes the PCR from being counted.

NOTE 2 If a command causes PCR in multiple banks to change, the PCR Update Counter must be incremented once for each bank. The commands that extend PCR are: TPM2_PCR_Extend, TPM2_PCR_Event, and TPM2_EventSequenceComplete.

If a command resets PCR in multiple banks, the PCR Update Counter must be incremented only once. The commands that reset PCR are: TPM2_PCR_Reset, and TPM2_Startup.

A platform-specific specification may designate a set of PCR that are under control of the TCB. These PCR may not be modified without the proper authorization. Updates of these PCR shall not cause the PCR Update Counter to increment.

EXAMPLE Updates of the TCB PCR will not cause the PCR update counter to increment because these PCR are changed at the whim of the TCB and may not represent the trust state of the platform.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

22.2 TPM2_PCR_Extend

22.2.1 General Description

This command is used to cause an update to the indicated PCR. The *digests* parameter contains one or more tagged digest values identified by an algorithm ID. For each digest, the PCR associated with *pcrHandle* is Extended into the bank identified by the tag (*hashAlg*).

EXAMPLE A SHA1 digest would be Extended into the SHA1 bank and a SHA256 digest would be Extended into the SHA256 bank.

For each list entry, the TPM will check to see if *pcrNum* is implemented for that algorithm. If so, the TPM shall perform the following operation:

$$PCR.digest_{new}[pcrNum][alg] \coloneqq \mathbf{H}_{alg}(PCR.digest_{old}[pcrNum][alg] \mid\mid data[alg].buffer) \quad (6)$$

where

$\mathbf{H}_{alg}()$	hash function using the hash algorithm associated with the PCR instance
$PCR.digest$	the digest value in a PCR
$pcrNum$	the PCR numeric selector (*pcrHandle*)
alg	the PCR algorithm selector for the digest
$data[alg].buffer$	the bank-specific data to be extended

If no digest value is specified for a bank, then the PCR in that bank is not modified.

NOTE 1 This allows consistent operation of the digests list for all of the Event recording commands.

If a digest is present and the PCR in that bank is not implemented, the digest value is not used.

NOTE 2 If the caller includes digests for algorithms that are not implemented, then the TPM will fail the call because the unmarshalling of *digests* will fail. Each of the entries in the list is a TPMT_HA, which is a hash algorithm followed by a digest. If the algorithm is not implemented, unmarshalling of the *hashAlg* will fail and the TPM will return TPM_RC_HASH.

If the TPM unmarshals the *hashAlg* of a list entry and the unmarshaled value is not a hash algorithm implemented on the TPM, the TPM shall return TPM_RC_HASH.

The *pcrHandle* parameter is allowed to reference TPM_RH_NULL. If so, the input parameters are processed but no action is taken by the TPM. This permits the caller to probe for implemented hash algorithms as an alternative to TPM2_GetCapability.

NOTE 3 This command allows a list of digests so that PCR in all banks may be updated in a single command. While the semantics of this command allow multiple extends to a single PCR bank, this is not the preferred use and the limit on the number of entries in the list make this use somewhat impractical.

22.3 TPM2_PCR_Event

22.3.1 General Description

This command is used to cause an update to the indicated PCR.

The data in *eventData* is hashed using the hash algorithm associated with each bank in which the indicated PCR has been allocated. After the data is hashed, the *digests* list is returned. If the *pcrHandle* references an implemented PCR and not TPM_RH_NULL, the *digests* list is processed as in TPM2_PCR_Extend().

A TPM shall support an *Event.size* of zero through 1,024 inclusive (*Event.size* is an octet count). An *Event.size* of zero indicates that there is no data but the indicated operations will still occur,

EXAMPLE 1 If the command implements PCR[2] in a SHA1 bank and a SHA256 bank, then an extend to PCR[2] will cause *eventData* to be hashed twice, once with SHA1 and once with SHA256. The SHA1 hash of *eventData* will be Extended to PCR[2] in the SHA1 bank and the SHA256 hash of *eventData* will be Extended to PCR[2] of the SHA256 bank.

On successful command completion, *digests* will contain the list of tagged digests of *eventData* that was computed in preparation for extending the data into the PCR. At the option of the TPM, the list may contain a digest for each bank, or it may only contain a digest for each bank in which *pcrHandle* is extant. If *pcrHandle* is TPM_RH_NULL, the TPM may return either an empty list or a digest for each bank.

EXAMPLE 2 Assume a TPM that implements a SHA1 bank and a SHA256 bank and that PCR[22] is only implemented in the SHA1 bank. If *pcrHandle* references PCR[22], then *digests* may contain either a SHA1 and a SHA256 digest or just a SHA1 digest.

22.4 TPM2_PCR_Read

22.4.1 General Description

This command returns the values of all PCR specified in *pcrSelectionIn*.

The TPM will process the list of TPMS_PCR_SELECTION in *pcrSelectionIn* in order. Within each TPMS_PCR_SELECTION, the TPM will process the bits in the *pcrSelect* array in ascending PCR order (see TPM 2.0 Part 1, *Selecting Multiple PCR*). If a bit is SET, and the indicated PCR is present, then the TPM will add the digest of the PCR to the list of values to be returned in *pcrValues.*

The TPM will continue processing bits until all have been processed or until *pcrValues* would be too large to fit into the output buffer if additional values were added.

The returned *pcrSelectionOut* will have a bit SET in its *pcrSelect* structures for each value present in *pcrValues*.

The current value of the PCR Update Counter is returned in *pcrUpdateCounter*.

The returned list may be empty if none of the selected PCR are implemented.

NOTE If no PCR are returned from a bank, the selector for the bank will be present in *pcrSelectionOut*.

No authorization is required to read a PCR and any implemented PCR may be read from any locality.

22.5 TPM2_PCR_Allocate

22.5.1 General Description

This command is used to set the desired PCR allocation of PCR and algorithms. This command requires Platform Authorization.

The TPM will evaluate the request and, if sufficient memory is available for the requested allocation, the TPM will store the allocation request for use during the next _TPM_Init operation. The PCR allocation in place when this command is executed will be retained until the next _TPM_Init. If this command is received multiple times before a _TPM_Init, each one overwrites the previous stored allocation.

This command will only change the allocations of banks that are listed in *pcrAllocation*.

EXAMPLE 1 If a TPM supports SHA1 and SHA256, then it maintains an allocation for two banks (one of which could be empty). If *pcrAllocation* only has a selector for the SHA1 bank, then only the allocation of the SHA1 bank will be changed and the SHA256 bank will remain unchanged. To change the allocation of a TPM from 24 SHA1 PCR and no SHA256 PCR to 24 SHA256 PCR and no SHA1 PCR, the *pcrAllocation* would have to have two selections: one for the empty SHA1 bank and one for the SHA256 bank with 24 PCR.

If a bank is listed more than once, then the last selection in the *pcrAllocation* list is the one that the TPM will attempt to allocate.

NOTE 1 This does not mean to imply that *pcrAllocation.count* can exceed HASH_COUNT, the number of digests implemented in the TPM.

EXAMPLE 2 If HASH_COUNT is 2, *pcrAllocation* can specify SHA-256 twice, and the second one is used. However, if SHA_256 is specified three times, the unmarshaling may fail and the TPM may return an error.

This command shall not allocate more PCR in any bank than there are PCR attribute definitions. The PCR attribute definitions indicate how a PCR is to be managed – if it is resettable, the locality for update, etc. In the response to this command, the TPM returns the maximum number of PCR allowed for any bank.

When PCR are allocated, if DRTM_PCR is defined, the resulting allocation must have at least one bank with the D-RTM PCR allocated. If HCRTM_PCR is defined, the resulting allocation must have at least one bank with the HCRTM_PCR allocated. If not, the TPM returns TPM_RC_PCR.

The TPM may return TPM_RC_SUCCESS even though the request fails. This is to allow the TPM to return information about the size needed for the requested allocation and the size available. If the *sizeNeeded* parameter in the return is less than or equal to the *sizeAvailable* parameter, then the *allocationSuccess* parameter will be YES. Alternatively, if the request fails, The TPM may return TPM_RC_NO_RESULT.

NOTE 2 An example for this type of failure is a TPM that can only support one bank at a time and cannot support arbitrary distribution of PCR among banks.

After this command, TPM2_Shutdown() is only allowed to have a *startupType* equal to TPM_SU_CLEAR until after the next _TPM_Init.

NOTE 3 Even if this command does not cause the PCR allocation to change, the TPM cannot have its state saved. This is done in order to simplify the implementation. There is no need to optimize this command as it is not expected to be used more than once in the lifetime of the TPM (it can be used any number of times but there is no justification for optimization).

22.6 TPM2_PCR_SetAuthPolicy

22.6.1 General Description

This command is used to associate a policy with a PCR or group of PCR. The policy determines the conditions under which a PCR may be extended or reset.

A policy may only be associated with a PCR that has been defined by a platform-specific specification as allowing a policy. If the TPM implementation does not allow a policy for *pcrNum*, the TPM shall return TPM_RC_VALUE.

A platform-specific specification may group PCR so that they share a common policy. In such case, a *pcrNum* that selects any of the PCR in the group will change the policy for all PCR in the group.

The policy setting is persistent and may only be changed by TPM2_PCR_SetAuthPolicy() or by TPM2_ChangePPS().

Before this command is first executed on a TPM or after TPM2_ChangePPS(), the access control on the PCR will be set to the default value defined in the platform-specific specification.

NOTE 1 It is expected that the typical default will be with the policy hash set to TPM_ALG_NULL and an Empty Buffer for the *authPolicy* value. This will allow an *EmptyAuth* to be used as the authorization value.

If the size of the data buffer in *authPolicy* is not the size of a digest produced by *hashAlg*, the TPM shall return TPM_RC_SIZE.

NOTE 2 If *hashAlg* is TPM_ALG_NULL, then the size is required to be zero.

This command requires platformAuth/platformPolicy.

NOTE 3 If the PCR is in multiple policy sets, the policy will be changed in only one set. The set that is changed will be implementation dependent.

22.7 TPM2_PCR_SetAuthValue

22.7.1 General Description

This command changes the *authValue* of a PCR or group of PCR.

An *authValue* may only be associated with a PCR that has been defined by a platform-specific specification as allowing an authorization value. If the TPM implementation does not allow an authorization for *pcrNum*, the TPM shall return TPM_RC_VALUE. A platform-specific specification may group PCR so that they share a common authorization value. In such case, a *pcrNum* that selects any of the PCR in the group will change the *authValue* value for all PCR in the group.

The authorization setting is set to EmptyAuth on each STARTUP(CLEAR) or by TPM2_Clear(). The authorization setting is preserved by SHUTDOWN(STATE).

22.8 TPM2_PCR_Reset

22.8.1 General Description

If the attribute of a PCR allows the PCR to be reset and proper authorization is provided, then this command may be used to set the PCR in all banks to zero. The attributes of the PCR may restrict the locality that can perform the reset operation.

NOTE 1 The definition of TPMI_DH_PCR in TPM 2.0 Part 2 indicates that if pcrHandle is out of the allowed range for PCR, then the appropriate return value is TPM_RC_VALUE.

If *pcrHandle* references a PCR that cannot be reset, the TPM shall return TPM_RC_LOCALITY.

NOTE 2 TPM_RC_LOCALITY is returned because the reset attributes are defined on a per-locality basis.

22.9 _TPM_Hash_Start

22.9.1 Description

This indication from the TPM interface indicates the start of an H-CRTM measurement sequence. On receipt of this indication, the TPM will initialize an H-CRTM Event Sequence context.

If no object memory is available for creation of the sequence context, the TPM will flush the context of an object so that creation of the sequence context will always succeed.

A platform-specific specification may allow this indication before TPM2_Startup().

NOTE If this indication occurs after TPM2_Startup(), it is the responsibility of software to ensure that an object context slot is available or to deal with the consequences of having the TPM select an arbitrary object to be flushed. If this indication occurs before TPM2_Startup() then all context slots are available.

22.9.2 Detailed Actions

```
1   #include "Tpm.h"
```

This function is called to process a _TPM_Hash_Start() indication.

```
2   LIB_EXPORT void
3   _TPM_Hash_Start(
4       void
5       )
6   {
7       TPM_RC              result;
8       TPMI_DH_OBJECT      handle;
9
10      // If a DRTM sequence object exists, free it up
11      if(g_DRTMHandle != TPM_RH_UNASSIGNED)
12      {
13          FlushObject(g_DRTMHandle);
14          g_DRTMHandle = TPM_RH_UNASSIGNED;
15      }
16
17      // Create an event sequence object and store the handle in global
18      // g_DRTMHandle. A TPM_RC_OBJECT_MEMORY error may be returned at this point
19      // The NULL value for the first parameter will cause the sequence structure to
20      // be allocated without being set as present. This keeps the sequence from
21      // being left behind if the sequence is terminated early.
22      result = ObjectCreateEventSequence(NULL, &g_DRTMHandle);
23
24      // If a free slot was not available, then free up a slot.
25      if(result != TPM_RC_SUCCESS)
26      {
27          // An implementation does not need to have a fixed relationship between
28          // slot numbers and handle numbers. To handle the general case, scan for
29          // a handle that is assigned and free it for the DRTM sequence.
30          // In the reference implementation, the relationship between handles and
31          // slots is fixed. So, if the call to ObjectCreateEvenSequence()
32          // failed indicating that all slots are occupied, then the first handle we
33          // are going to check (TRANSIENT_FIRST) will be occupied. It will be freed
34          // so that it can be assigned for use as the DRTM sequence object.
35          for(handle = TRANSIENT_FIRST; handle < TRANSIENT_LAST; handle++)
36          {
37              // try to flush the first object
38              if(IsObjectPresent(handle))
39                  break;
40          }
41          // If the first call to find a slot fails but none of the slots is occupied
42          // then there's a big problem
43          pAssert(handle < TRANSIENT_LAST);
44
45          // Free the slot
46          FlushObject(handle);
47
48          // Try to create an event sequence object again.  This time, we must
49          // succeed.
50          result = ObjectCreateEventSequence(NULL, &g_DRTMHandle);
51          if(result != TPM_RC_SUCCESS)
52              FAIL(FATAL_ERROR_INTERNAL);
53      }
54
55      return;
56  }
```

22.10 _TPM_Hash_Data

22.10.1 Description

This indication from the TPM interface indicates arrival of one or more octets of data that are to be included in the H-CRTM Event Sequence sequence context created by the _TPM_Hash_Start indication. The context holds data for each hash algorithm for each PCR bank implemented on the TPM.

If no H-CRTM Event Sequence context exists, this indication is discarded and no other action is performed.

```

This function is called to process a _TPM_Hash_Data() indication.

```
2  LIB_EXPORT void
3  _TPM_Hash_Data(
4      uint32_t         dataSize,       // IN: size of data to be extend
5      unsigned char   *data            // IN: data buffer
6      )
7  {
8      UINT32           i;
9      HASH_OBJECT     *hashObject;
10     TPMI_DH_PCR      pcrHandle = TPMIsStarted()
11         ? PCR_FIRST + DRTM_PCR : PCR_FIRST + HCRTM_PCR;
12
13 // If there is no DRTM sequence object, then _TPM_Hash_Start
14 // was not called so this function returns without doing
15 // anything.
16     if(g_DRTMHandle == TPM_RH_UNASSIGNED)
17         return;
18
19     hashObject = (HASH_OBJECT *)HandleToObject(g_DRTMHandle);
20     pAssert(hashObject->attributes.eventSeq);
21
22     // For each of the implemented hash algorithms, update the digest with the
23     // data provided.
24     for(i = 0; i < HASH_COUNT; i++)
25     {
26         // make sure that the PCR is implemented for this algorithm
27         if(PcrIsAllocated(pcrHandle,
28                           hashObject->state.hashState[i].hashAlg))
29           // Update sequence object
30             CryptDigestUpdate(&hashObject->state.hashState[i], dataSize, data);
31     }
32
33     return;
34 }
```

22.11 _TPM_Hash_End

22.11.1 Description

This indication from the TPM interface indicates the end of the H-CRTM measurement. This indication is discarded and no other action performed if the TPM does not contain an H-CRTM Event Sequence context.

NOTE 1 An H-CRTM Event Sequence context is created by _TPM_Hash_Start().

If the H-CRTM Event Sequence occurs after TPM2_Startup(), the TPM will set all of the PCR designated in the platform-specific specifications as resettable by this event to the value indicated in the platform specific specification and increment *restartCount*. The TPM will then Extend the Event Sequence digest/digests into the designated D-RTM PCR (PCR[17]).

$$\text{PCR}[17][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(initial_value \,||\, \mathbf{H}_{hashAlg}(hash_data)) \quad (7)$$

where

$hashAlg$	hash algorithm associated with a bank of PCR
$initial_value$	initialization value specified in the platform-specific specification (should be 0…0)
$hash_data$	all the octets of data received in _TPM_Hash_Data indications

A _TPM_Hash_End indication that occurs after TPM2_Startup() will increment *pcrUpdateCounter* unless a platform-specific specification excludes modifications of PCR[DRTM] from causing an increment.

A platform-specific specification may allow an H-CRTM Event Sequence before TPM2_Startup(). If so, _TPM_Hash_End will complete the digest, initialize PCR[0] with a digest-size value of 4, and then extend the H-CRTM Event Sequence data into PCR[0].

$$\text{PCR}[0][hashAlg] \coloneqq \mathbf{H}_{hashAlg}(0\ldots04 \,||\, \mathbf{H}_{hashAlg}(hash_data)) \quad (8)$$

NOTE 2 The entire sequence of _TPM_Hash_Start, _TPM_Hash_Data, and _TPM_Hash_End are required to complete before TPM2_Startup() or the sequence will have no effect on the TPM.

NOTE 3 PCR[0] does not need to be updated according to (8) until the end of TPM2_Startup().

23 Enhanced Authorization (EA) Commands

23.1 Introduction

The commands in this clause 1 are used for policy evaluation. When successful, each command will update the *policySession→policyDigest* in a policy session context in order to establish that the authorizations required to use an object have been provided. Many of the commands will also modify other parts of a policy context so that the caller may constrain the scope of the authorization that is provided.

NOTE 1 Many of the terms used in this clause are described in detail in TPM 2.0 Part 1 and are not redefined in this clause.

The *policySession* parameter of the command is the handle of the policy session context to be modified by the command.

If the *policySession* parameter indicates a trial policy session, then the *policySession→policyDigest* will be updated and the indicated validations are not performed. However, any authorizations required to perform the policy command will be checked and dictionary attack logic invoked as necessary.

NOTE 2 If software is used to create policies, no authorization values are used. For example, TPM_PolicySecret requires an authorization in a trial policy session, but not in a policy calculation outside the TPM.

NOTE 3 A policy session is set to a trial policy by TPM2_StartAuthSession(*sessionType* = TPM_SE_TRIAL).

NOTE 4 Unless there is an unmarshaling error in the parameters of the command, these commands will return TPM_RC_SUCCESS when *policySession* references a trial session.

NOTE 5 Policy context other than the *policySession→policyDigest* may be updated for a trial policy but it is not required.

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

23.2 Signed Authorization Actions

23.2.1 Introduction

The TPM2_PolicySigned, TPM_PolicySecret, and TPM2_PolicyTicket commands use many of the same functions. This clause consolidates those functions to simplify the document and to ensure uniformity of the operations.

23.2.2 Policy Parameter Checks

These parameter checks will be performed when indicated in the description of each of the commands:

a) *nonceTPM* – If this parameter is not the Empty Buffer, and it does not match *policySession→nonceTPM*, then the TPM shall return TPM_RC_VALUE.

b) *expiration* – If this parameter is not zero, then:

   1) if *nonceTPM* is not an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and added to *policySession→startTime* to create the *timeout* value and proceed to c).

   2) If *nonceTPM* is an Empty Buffer, then the absolute value of *expiration* is converted to milliseconds and used as the *timeout* value and proceed to c).

   However, *timeout* can only be changed to a smaller value.

c) *timeout* – If *timeout* is less than the current value of *Time*, or the current *timeEpoch* is not the same as *policySession→timeEpoch, the* TPM shall return TPM_RC_EXPIRED

d) *cpHashA* – If this parameter is not an Empty Buffer

   NOTE 2 *cpHashA* is the hash of the command to be executed using this policy session in the authorization. The algorithm used to compute this hash is required to be the algorithm of the policy session.

   1) the TPM shall return TPM_RC_CPHASH if *policySession→cpHash* is set and the contents of *policySession→cpHash* are not the same as *cpHashA*; or

      NOTE 3 cpHash is the expected cpHash value held in the policy session context.

   2) the TPM shall return TPM_RC_SIZE if *cpHashA* is not the same size as *policySession→policyDigest*.

      NOTE 4 policySession→policyDigest is the size of the digest produced by the hash algorithm used to compute policyDigest.

23.2.3 Policy Digest Update Function (PolicyUpdate())

This is the update process for *policySession→policyDigest* used by TPM2_PolicySigned(), TPM2_PolicySecret(), TPM2_PolicyTicket(), and TPM2_PolicyAuthorize(). The function prototype for the update function is:

$$\mathbf{PolicyUpdate}(commandCode, arg2, arg3) \tag{9}$$

where

$arg2$	a TPM2B_NAME
$arg3$	a TPM2B

These parameters are used to update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid commandCode \mid\mid arg2.name) \tag{10}$$

followed by

$$policyDigest_{new+1} \coloneqq \mathbf{H}_{\mathrm{policyAlg}}(policyDigest_{new} \mid\mid arg3.buffer) \tag{11}$$

where

$\mathbf{H}_{policyAlg}()$	the hash algorithm chosen when the policy session was started

NOTE 1 If *arg3* is a TPM2B_NAME, then *arg3.buffer* will actually be an *arg3.name*.

NOTE 2 The *arg2.size* and *arg3.size* fields are not included in the hashes.

NOTE 3 **PolicyUpdate**() uses two hash operations because *arg2* and *arg3* are variable-sized and the concatenation of *arg2* and *arg3* in a single hash could produce the same digest even though *arg2* and *arg3* are different. For example, arg2 = 1 2 3 and arg3 = 4 5 6 would produce the same digest as arg2 = 1 2 and arg3 = 3 4 5 6. Processing of the arguments separately in different Extend operation ensures that the digest produced by **PolicyUpdate**() will be different if *arg2* and *arg3* are different.

 Copyright © TCG 2006-2020

23.2.4 Policy Context Updates

When a policy command modifies some part of the policy session context other than the *policySession→policyDigest*, the following rules apply.

- ***cpHash*** – this parameter may only be changed if it contains its initialization value (an Empty Buffer). If *cpHash* is not the Empty Buffer when a policy command attempts to update it, the TPM will return an error (TPM_RC_CPHASH) if the current and update values are not the same.
- ***timeOut*** – this parameter may only be changed to a smaller value. If a command attempts to update this value with a larger value (longer into the future), the TPM will discard the update value. This is not an error condition.
- ***commandCode*** – once set by a policy command, this value may not be changed except by TPM2_PolicyRestart(). If a policy command tries to change this to a different value, an error is returned (TPM_RC_POLICY_CC).
- ***pcrUpdateCounter*** – this parameter is updated by TPM2_PolicyPCR(). This value may only be set once during a policy. Each time TPM2_PolicyPCR() executes, it checks to see if *policySession→pcrUpdateCounter* has its default state, indicating that this is the first TPM2_PolicyPCR(). If it has its default value, then *policySession→pcrUpdateCounter* is set to the current value of *pcrUpdateCounter*. If *policySession→pcrUpdateCounter* does not have its default value and its value is not the same as *pcrUpdateCounter*, the TPM shall return TPM_RC_PCR_CHANGED.

  NOTE 1 If this parameter and *pcrUpdateCounter* are not the same, it indicates that PCR have changed since checked by the previous TPM2_PolicyPCR(). Since they have changed, the previous PCR validation is no longer valid.

- ***commandLocality*** – this parameter is the logical AND of all enabled localities. All localities are enabled for a policy when the policy session is created. TPM2_PolicyLocalities() selectively disables localities. Once use of a policy for a locality has been disabled, it cannot be enabled except by TPM2_PolicyRestart().
- ***isPPRequired*** – once SET, this parameter may only be CLEARed by TPM2_PolicyRestart().
- ***isAuthValueNeeded*** – once SET, this parameter may only be CLEARed by TPM2_PolicyPassword() or TPM2_PolicyRestart().
- ***isPasswordNeeded*** – once SET, this parameter may only be CLEARed by TPM2_PolicyAuthValue() or TPM2_PolicyRestart(),

NOTE 2 Both TPM2_PolicyAuthValue() and TPM2_PolicyPassword() change *policySession→policyDigest* in the same way. The different commands simply indicate to the TPM the format used for the *authValue* (HMAC or clear text). Both commands could be in the same policy. The final instance of these commands determines the format.

 Copyright © TCG 2006-2020

23.2.5 Policy Ticket Creation

For TPM2_PolicySigned() or TPM2_PolicySecret(), if the caller specified a negative value for *expiration*, then the TPM will return a ticket that includes a value indicating when the authorization expires. Otherwise, the TPM will return a NULL Ticket.

NOTE 1 If the *authHandle* in TPM2_PolicySecret() references a PIN Pass Index, then the command may succeed but a NULL Ticket will be returned.

The required computation for the digest in the authorization ticket is:

$$\mathbf{HMAC}_{contextAlg}(proof, (\text{TPM_ST_AUTH_xxx} \mid\mid cpHash \mid\mid policyRef \mid\mid authName \mid\mid timeout \mid\mid [timeEpoch] \mid\mid [resetCount])) \quad (12)$$

where

$\mathbf{HMAC}_{contextAlg}()$	an HMAC using the context integrity hash
$proof$	a TPM secret value associated with the hierarchy of the object associated with *authName*
TPM_ST_AUTH_xxx	either TPM_ST_AUTH_SIGNED or TPM_ST_AUTH_SECRET; used to ensure that the ticket is properly used
$cpHash$	optional hash of the authorized command
$policyRef$	optional reference to a policy value
$authName$	Name of the object that signed the authorization
$timeout$	implementation-specific value indicating when the authorization expires
$timeEpoch$	implementation-specific representation of the $timeEpoch$ at the time the ticket was created

NOTE 2 Not included if *timeout* is zero.

$resetCount$	implementation-specific representation of the TPM's *totalResetCount*

NOTE 3 Not included it *timeout* is zero or if *nonceTPM* was include in the authorization.

 Copyright © TCG 2006-2020

23.3 TPM2_PolicySigned

23.3.1 General Description

This command includes a signed authorization in a policy. The command ties the policy to a signing key by including the Name of the signing key in the *policyDigest*

If *policySession* is a trial session, the TPM will not check the signature and will update *policySession→policyDigest* as described in 23.2.3 as if a properly signed authorization was received, but no ticket will be produced.

If *policySession* is not a trial session, the TPM will validate *auth* and only perform the update if it is a valid signature over the fields of the command.

The authorizing entity will sign a digest of the authorization qualifiers: *nonceTPM*, *expiration*, *cpHashA*, and *policyRef*. The digest is computed as:

$$aHash \coloneqq \mathbf{H}_{authAlg}(nonceTPM \mid\mid expiration \mid\mid cpHashA \mid\mid policyRef) \qquad (13)$$

where

$\mathbf{H}_{authAlg}()$ the hash associated with the auth parameter of this command

NOTE 1 Each signature and key combination indicates the scheme and each scheme has an associated hash.

$nonceTPM$ the nonceTPM parameter from the TPM2_StartAuthSession() response. If the authorization is not limited to this session, the size of this value is zero.

$expiration$ time limit on authorization set by authorizing object. This 32-bit value is set to zero if the expiration time is not being set.

$cpHashA$ digest of the command parameters for the command being approved using the hash algorithm of the policy session. Set to an Empty Digest if the authorization is not limited to a specific command.

NOTE 3 This is not the *cpHash* of this TPM2_PolicySigned() command.

$policyRef$ an opaque value determined by the authorizing entity. Set to the Empty Buffer if no value is present.

NOTE 4 The *nonceTPM*, *cpHashA*, and *policyRef* qualifiers used to compute *aHash* use the TPM2B buffer but do not prepend the size.

EXAMPLE The computation for an *aHash* if there are no restrictions is:

$$aHash \coloneqq \mathbf{H}_{authAlg}(00\ 00\ 00\ 00_{16})$$

which is the hash of an expiration time of zero.

The *aHash* is signed by the key associated with a key whose handle is *authObject*. The signature and signing parameters are combined to create the *auth* parameter.

The TPM will perform the parameter checks listed in 23.2.2

If the parameter checks succeed, the TPM will construct a test digest (*tHash*) over the provided parameters using the same formulation as shown in equation (13) above.

If *tHash* does not match the digest of the signed *aHash,* then the authorization fails and the TPM shall return TPM_RC_POLICY_FAIL and make no change to *policySession→policyDigest*.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

When all validations have succeeded, *policySession→policyDigest* is updated by **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(\text{TPM_CC_PolicySigned}, authObject{\rightarrow}Name, policyRef) \tag{14}$$

authObject→Name is a TPM2B_NAME. *policySession* is updated as described in 23.2.4. The TPM will optionally produce a ticket as described in 23.2.5.

Authorization to use *authObject* is not required.

23.3.2 Command and Response

Table 124 — TPM2_PolicySigned Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit, encrypt, or decrypt session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_PolicySigned
TPMI_DH_OBJECT	authObject	handle for a key that will validate the signature Auth Index: None
TPMI_SH_POLICY	policySession	handle for the policy session being extended Auth Index: None
TPM2B_NONCE	nonceTPM	the policy nonce for the session This can be the Empty Buffer.
TPM2B_DIGEST	cpHashA	digest of the command parameters to which this authorization is limited This is not the *cpHash* for this command but the *cpHash* for the command to which this policy session will be applied. If it is not limited, the parameter will be the Empty Buffer.
TPM2B_NONCE	policyRef	a reference to a policy relating to the authorization – may be the Empty Buffer Size is limited to be no larger than the nonce size supported on the TPM.
INT32	expiration	time when authorization will expire, measured in seconds from the time that *nonceTPM* was generated If *expiration* is non-negative, a NULL Ticket is returned. See 23.2.5.
TPMT_SIGNATURE	auth	signed authorization (not optional)

Table 125 — TPM2_PolicySigned Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPM2B_TIMEOUT	timeout	implementation-specific time value, used to indicate to the TPM when the ticket expires NOTE If *policyTicket* is a NULL Ticket, then this shall be the Empty Buffer.
TPMT_TK_AUTH	policyTicket	produced if the command succeeds and *expiration* in the command was non-zero; this ticket will use the TPMT_ST_AUTH_SIGNED structure tag. See 23.2.5

23.4 TPM2_PolicySecret

23.4.1 General Description

This command includes a secret-based authorization to a policy. The caller proves knowledge of the secret value using an authorization session using the *authValue* associated with *authHandle*. A password session, an HMAC session, or a policy session containing TPM2_PolicyAuthValue() or TPM2_PolicyPassword() will satisfy this requirement.

If a policy session is used and use of the *authValue* of *authHandle* is not required, the TPM will return TPM_RC_MODE. That is, the session for *authHandle* must have either *isAuthValueNeeded* or *isPasswordNeeded* SET.

The secret is the *authValue* of the entity whose handle is *authHandle,* which may be any TPM entity with a handle and an associated *authValue*. This includes the reserved handles (for example, Platform, Storage, and Endorsement), NV Indexes, and loaded objects. *authEntity* is the entity referenced by *authHandle*. If *authEntity* references an Ordinary object, it must have *userWithAuth* SET.

NOTE 1 The *userWithAuth* requirement permits the implementation to use common authorization code.

If *authEntity* references a non-PIN Index, TPMA_NV_AUTHREAD is required to be SET in the Index. If *authEntity* references an NV PIN index, TPMA_NV_WRITTEN is required to be SET and *pinCount* must be less than *pinLimit*.

NOTE 2 The authorization value for a hierarchy cannot be used in this command if the hierarchy is disabled.

If the authorization check fails, then the normal dictionary attack logic is invoked.

If the authorization provided by the authorization session is valid, the command parameters are checked as described in 23.2.2.

When all validations have succeeded, *policySession→policyDigest* is updated by **PolicyUpdate**() (see 23.2.3).

$$\textbf{PolicyUpdate}(\text{TPM_CC_PolicySecret}, authEntity\rightarrow Name, policyRef) \quad (15)$$

authEntity→Name is a TPM2B_NAME. *policySession* is updated as described in 23.2.4. The TPM will optionally produce a ticket as described in 23.2.5.

If the session is a trial session, *policySession→policyDigest* is updated if the authorization is valid.

NOTE 2 If an HMAC is used to convey the authorization, a separate session is needed for the authorization. Because the HMAC in that authorization will include a nonce that prevents replay of the authorization, the value of the *nonceTPM* parameter in this command is limited. It is retained mostly to provide processing consistency with TPM2_PolicySigned().

```

23.5 TPM2_PolicyTicket

23.5.1 General Description

This command is similar to TPM2_PolicySigned() except that it takes a ticket instead of a signed authorization. The ticket represents a validated authorization that had an expiration time associated with it.

The parameters of this command are checked as described in 23.2.2.

If the checks succeed, the TPM uses the *timeout*, *cpHashA*, *policyRef*, and *authName* to construct a ticket to compare with the value in *ticket*. If these tickets match, then the TPM will create a TPM2B_NAME (*objectName*) using *authName* and update the context of *policySession* by **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(commandCode, authName, policyRef) \quad (16)$$

If the structure tag of ticket is TPM_ST_AUTH_SECRET, then *commandCode* will be TPM_CC_PolicySecret. If the structure tag of ticket is TPM_ST_AUTH_SIGNED, then *commandCode* will be TPM_CC_PolicySIgned.

policySession is updated as described in 23.2.4.

23.6 TPM2_PolicyOR

23.6.1 General Description

This command allows options in authorizations without requiring that the TPM evaluate all of the options. If a policy may be satisfied by different sets of conditions, the TPM need only evaluate one set that satisfies the policy. This command will indicate that one of the required sets of conditions has been satisfied.

PolicySession→policyDigest is compared against the list of provided values. If the current *policySession→policyDigest* does not match any value in the list, the TPM shall return TPM_RC_VALUE. Otherwise, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then *policySession→policyDigest* is extended by the concatenation of TPM_CC_PolicyOR and the concatenation of all of the digests.

If *policySession* is a trial session, the TPM will assume that *policySession→policyDigest* matches one of the list entries and compute the new value of *policyDigest*.

The algorithm for computing the new value for *policyDigest* of *policySession* is:

a) Concatenate all the digest values in *pHashList*:

$$digests := pHashList.digests[1].buffer \mathbin{||} \ldots \mathbin{||} pHashList.digests[n].buffer \quad (17)$$

NOTE 1 The TPM will not return an error if the size of an entry is not the same as the size of the digest of the policy. However, that entry cannot match *policyDigest*.

b) Reset *policyDigest* to a Zero Digest.

c) Extend the command code and the hashes computed in step a) above:

$$policyDigest_{new} := \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyOR} \mathbin{||} digests) \quad (18)$$

NOTE 2 The computation in b) and c) above is equivalent to:

$$policyDigest_{new} := \mathbf{H}_{policyAlg}(0\ldots0 \mathbin{||} \text{TPM_CC_PolicyOR} \mathbin{||} digests)$$

A TPM shall support a list with at least eight tagged digest values.

NOTE 3 If policies are to be portable between TPMs, then they should not use more than eight values.

23.7 TPM2_PolicyPCR

23.7.1 General Description

This command is used to cause conditional gating of a policy based on PCR. This command together with TPM2_PolicyOR() allows one group of authorizations to occur when PCR are in one state and a different set of authorizations when the PCR are in a different state.

The TPM will modify the *pcrs* parameter so that bits that correspond to unimplemented PCR are CLEAR. If *policySession* is not a trial policy session, the TPM will use the modified value of pcrs to select PCR values to hash according to TPM 2.0 Part 1, *Selecting Multiple PCR.* The hash algorithm of the policy session is used to compute a digest (*digestTPM*) of the selected PCR. If *pcrDigest* does not have a length of zero, then it is compared to *digestTPM*; and if the values do not match, the TPM shall return TPM_RC_VALUE and make no change to *policySession→policyDigest*. If the values match, or if the length of *pcrDigest* is zero, then *policySession→policyDigest* is extended by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyPCR} \mathbin{||} pcrs \mathbin{||} digestTPM) \qquad (19)$$

where

$pcrs$	the pcrs parameter with bits corresponding to unimplemented PCR set to 0
$digestTPM$	the digest of the selected PCR using the hash algorithm of the policy session

NOTE 1 If the caller provides the expected PCR value, the intention is that the policy evaluation stop at that point if the PCR do not match. If the caller does not provide the expected PCR value, then the validity of the settings will not be determined until an attempt is made to use the policy for authorization. If the policy is constructed such that the PCR check comes before user authorization checks, this early termination would allow software to avoid unnecessary prompts for user input to satisfy a policy that would fail later due to incorrect PCR values.

After this command completes successfully, the TPM shall return TPM_RC_PCR_CHANGED if the policy session is used for authorization and the PCR are not known to be correct.

The TPM uses a "generation" number (*pcrUpdateCounter*) that is incremented each time PCR are updated (unless the PCR being changed is specified not to cause a change to this counter). The value of this counter is stored in the policy session context (*policySession→pcrUpdateCounter*) when this command is executed. When the policy is used for authorization, the current value of the counter is compared to the value in the policy session context and the authorization will fail if the values are not the same.

When this command is executed, *policySession→pcrUpdateCounter* is checked to see if it has been previously set (in the reference implementation, it has a value of zero if not previously set). If it has been set, it will be compared with the current value of *pcrUpdateCounter* to determine if any PCR changes have occurred. If the values are different, the TPM shall return TPM_RC_PCR_CHANGED.

NOTE 2 Since the pcrUpdateCounter is updated if any PCR is extended (except those specified not to do so), this means that the command will fail even if a PCR not specified in the policy is updated. This is an optimization for the purposes of conserving internal TPM memory. This would be a rare occurrence, and, if this should occur, the policy could be reset using the TPM2_PolicyRestart command and rerun.

If *policySession→pcrUpdateCounter* has not been set, then it is set to the current value of *pcrUpdateCounter*.

If this command is used for a trial *policySession*, *policySession→policyDigest* will be updated using the values from the command rather than the values from a digest of the TPM PCR. If the caller does not provide PCR settings (*pcrDigest* has a length of zero), the TPM may (and it is preferred to) use the current TPM PCR settings (*digestTPM)* in the calculation for the new *policyDigest*. The TPM may return

 Copyright © TCG 2006-2020

an error if the caller does not provide a PCR digest for a trial policy session but this is not the preferred behavior.

The TPM will not check any PCR and will compute:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyPCR} \mathbin{||} pcrs \mathbin{||} pcrDigest) \qquad (20)$$

In this computation, pcrs is the input parameter without modification.

NOTE 3 The pcrs parameter is expected to match the configuration of the TPM for which the policy is being computed which may not be the same as the TPM on which the trial policy is being computed.

NOTE 4 Although no PCR are checked in a trial policy session, *pcrDigest* is expected to correspond to some useful PCR values. It is legal, but pointless, to have the TPM aid in calculating a *policyDigest* corresponding to PCR values that are not useful in practice.

23.8 TPM2_PolicyLocality

23.8.1 General Description

This command indicates that the authorization will be limited to a specific locality.

policySession→commandLocality is a parameter kept in the session context. When the policy session is started, this parameter is initialized to a value that allows the policy to apply to any locality.

If *locality* has a value greater than 31, then an extended locality is indicated. For an extended locality, the TPM will validate that *policySession→commandLocality* has not previously been set or that the current value of *policySession→commandLocality* is the same as *locality* (TPM_RC_RANGE).

When *locality* is not an extended locality, the TPM will validate that the *policySession→commandLocality* is not set to an extended locality value (TPM_RC_RANGE). If not the TPM will disable any locality not SET in the *locality* parameter. If the result of disabling localities results in no locality being enabled, the TPM will return TPM_RC_RANGE.

If no error occurred in the validation of *locality*, *policySession→policyDigest* is extended with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyLocality} \mathbin{||} locality) \quad (21)$$

Then *policySession→commandLocality* is updated to indicate which localities are still allowed after execution of TPM2_PolicyLocality().

When the policy session is used to authorize a command, the authorization will fail if the locality used for the command is not one of the enabled localities in *policySession→commandLocality*.

```

23.9 TPM2_PolicyNV

23.9.1 General Description

This command is used to cause conditional gating of a policy based on the contents of an NV Index. It is an immediate assertion. The NV index is validated during the TPM2_PolicyNV() command, not when the session is used for authorization.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equations (22) and (23) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

An authorization session providing authorization to read the NV Index shall be provided.

If TPMA_NV_WRITTEN is not SET in the NV Index, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

operandA begins at *offset* into the NV index contents and has a size equal to the size of *operandB*. The TPM will perform the indicated arithmetic check using *operandA* and *operandB*. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession→policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args \coloneqq \mathbf{H}_{policyAlg}(operandB.buffer \mathbin{||} offset \mathbin{||} operation) \tag{22}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$operandB$	the value used for the comparison
$offset$	offset from the start of the NV Index data to start the comparison
$operation$	the operation parameter indicating the comparison being performed

The value of args and the Name of the NV Index are extended to *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyNV} \mathbin{||} args \mathbin{||} nvIndex{\rightarrow}Name) \tag{23}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$args$	value computed in equation (22)
$nvIndex{\rightarrow}Name$	the Name of the NV Index

The signed arithmetic operations are performed using twos-compliment.

Magnitude comparisons assume that the octet at offset zero in the referenced NV location and in *operandB* contain the most significant octet of the data.

23.10 TPM2_PolicyCounterTimer

23.10.1 General Description

This command is used to cause conditional gating of a policy based on the contents of the TPMS_TIME_INFO structure.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equations (24) and (25) below and return TPM_RC_SUCCESS. It will not perform any validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

The TPM will perform the indicated arithmetic check on the indicated portion of the TPMS_TIME_INFO structure. If the check fails, the TPM shall return TPM_RC_POLICY and not change *policySession→policyDigest*. If the check succeeds, the TPM will hash the arguments:

$$args \coloneqq \mathbf{H}_{policyAlg}(operandB.buffer \mathbin{||} offset \mathbin{||} operation) \tag{24}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$operandB.buffer$	the value used for the comparison
$offset$	offset from the start of the TPMS_TIME_INFO structure at which the comparison starts
$operation$	the operation parameter indicating the comparison being performed

NOTE There is no security related reason for the double hash.

The value of *args* is extended to *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyCounterTimer} \mathbin{||} args) \tag{25}$$

where

$\mathbf{H}_{policyAlg}()$	hash function using the algorithm of the policy session
$args$	value computed in equation (24)

The signed arithmetic operations are performed using twos-compliment. The indicated portion of the TPMS_TIME_INFO structure begins at *offset* and has a length of *operandB.size*. If the number of octets to be compared overflows the TPMS_TIME_INFO structure, the TPM returns TPM_RC_RANGE. If *offset* is greater than the size of the marshaled TPMS_TIME_INFO structure, the TPM returns TPM_RC_VALUE. The structure is marshaled into its canonical form with no padding. The TPM does not check for alignment of the offset with a TPMS_TIME_INFO structure member.

Magnitude comparisons assume that the octet at offset zero in the referenced location and in *operandB* contain the most significant octet of the data.

23.11 TPM2_PolicyCommandCode

23.11.1 General Description

This command indicates that the authorization will be limited to a specific command code.

If *policySession→commandCode* has its default value, then it will be set to *code.* If *policySession→commandCode* does not have its default value, then the TPM will return TPM_RC_VALUE if the two values are not the same.

If *code* is not implemented, the TPM will return TPM_RC_POLICY_CC.

If the TPM does not return an error, it will update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \,||\, \text{TPM_CC_PolicyCommandCode} \,||\, code) \quad (26)$$

NOTE 1 If a previous TPM2_PolicyCommandCode() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *code* is the same.

NOTE 2 A TPM2_PolicyOR() would be used to allow an authorization to be used for multiple commands.

When the policy session is used to authorize a command, the TPM will fail the command if the *commandCode* of that command does not match *policySession→commandCode*.

This command, or TPM2_PolicyDuplicationSelect(), is required to enable the policy to be used for ADMIN role authorization.

EXAMPLE Before TPM2_Certify() can be executed, TPM2_PolicyCommandCode() with code set to TPM_CC_Certify is required.

23.13 TPM2_PolicyCpHash

23.13.1 General Description

This command is used to allow a policy to be bound to a specific command and command parameters.

TPM2_PolicySigned(), TPM2_PolicySecret(), and TPM2_PolicyTIcket() are designed to allow an authorizing entity to execute an arbitrary command as the *cpHashA* parameter of those commands is not included in *policySession→policyDigest*. TPM2_PolicyCommandCode() allows the policy to be bound to a specific Command Code so that only certain entities may authorize specific command codes. This command allows the policy to be restricted such that an entity may only authorize a command with a specific set of parameters.

If *policySession→cpHash* is already set and not the same as *cpHashA*, then the TPM shall return TPM_RC_CPHASH. If *cpHashA* does not have the size of the *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE.

NOTE 1 If a previous TPM2_PolicyCpHash() had been executed, then it is probable that the policy expression is improperly formed but the TPM does not return an error if *cpHash* is the same.

If the *cpHashA* checks succeed, *policySession→cpHash* is set to *cpHashA* and *policySession→policyDigest* is updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \,||\, \text{TPM_CC_PolicyCpHash} \,||\, cpHashA) \quad (28)$$

23.14 TPM2_PolicyNameHash

23.14.1 General Description

This command allows a policy to be bound to a specific set of TPM entities without being bound to the parameters of the command. This is most useful for commands such as TPM2_Duplicate() and for TPM2_PCR_Event() when the referenced PCR requires a policy.

The *nameHash* parameter should contain the digest of the Names associated with the handles to be used in the authorized command.

EXAMPLE For the TPM2_Duplicate() command, two handles are provided. One is the handle of the object being duplicated and the other is the handle of the new parent. For that command, *nameHash* would contain:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectHandle{\rightarrow}Name \mid\mid newParentHandle{\rightarrow}Name)$$

If *policySession→cpHash* is already set, the TPM shall return TPM_RC_CPHASH. If the size of *nameHash* is not the size of *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession→cpHash* is set to *nameHash*.

If this command completes successfully, the *cpHash* of the authorized command will not be used for validation. Only the digest of the Names associated with the handles in the command will be used.

NOTE 1 This allows the space normally used to hold *policySession→cpHash* to be used for *policySession→nameHash* instead.

The *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyNameHash} \mid\mid nameHash) \quad (29)$$

NOTE 2 This command can only be used with TPM2_PolicyAuthorize() or TPM2_PolicyAuthorizeNV. The owner of the object being duplicated provides approval for their object to be migrated to a specific new parent.

Without this approval, the Name of the Object would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity.

23.15 TPM2_PolicyDuplicationSelect

23.15.1 General Description

This command allows qualification of duplication to allow duplication to a selected new parent.

If this command not used in conjunction with a PolicyAuthorize Command, then only the new parent is selected and *includeObject* should be CLEAR.

EXAMPLE When an object is created when the list of allowed duplication targets is known, the policy would be created with *includeObject* CLEAR.

NOTE 1 Only the new parent may be selected because, without TPM2_PolicyAuthorize(), the Name of the Object to be duplicated would need to be known at the time that Object's policy is created. However, since the Name of the Object includes its policy, the Name is not known. The Name can be known by the authorizing entity (a PolicyAuthorize Command) in which case *includeObject* may be SET.

If used in conjunction with TPM2_PolicyAuthorize(), then the authorizer of the new policy has the option of selecting just the new parent or of selecting both the new parent and the duplication Object.

NOTE 2 If the authorizing entity for an TPM2_PolicyAuthorize() only specifies the new parent, then that authorization may be applied to the duplication of any number of other Objects. If the authorizing entity specifies both a new parent and the duplicated Object, then the authorization only applies to that pairing of Object and new parent.

If either *policySession→cpHash* or *policySession→nameHash* has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, *policySession→nameHash* will be set to:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectName.name \mid\mid newParentName.name) \quad (30)$$

NOTE 3 It is allowed that policySesion→nameHash and policySession→cpHash share the same memory space.

NOTE 4 The Name in these equations uses Name.name, indicating that the UINT16 size is not included in the hash.

The *policySession→policyDigest* will be updated according to the setting of *includeObject*. If equal to YES, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyDuplicationSelect} \mid\mid objectName.name \mid\mid newParentName.name \mid\mid includeObject) \quad (31)$$

If includeObject is NO, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mid\mid \text{TPM_CC_PolicyDuplicationSelect} \mid\mid newParentName.name \mid\mid includeObject) \quad (32)$$

NOTE 5 *policySession→nameHash* receives the digest of both Names so that the check performed in TPM2_Duplicate() may be the same regardless of which Names are included in *policySession→policyDigest*. This means that, when TPM2_PolicyDuplicationSelect() is executed, it is only valid for a specific pair of duplication object and new parent.

If the command succeeds, *policySession→commandCode* is set to TPM_CC_Duplicate.

NOTE 6 The normal use of this command is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allowed duplication to a specific new parent. The authorizing entity may want to limit the authorization so that the approval allows only a specific object to be duplicated to the new parent. In that case, the authorizing entity would approve the *policyDigest* of *equation* (31).

23.16 TPM2_PolicyAuthorize

23.16.1 General Description

This command allows policies to change. If a policy were static, then it would be difficult to add users to a policy. This command lets a policy authority sign a new policy so that it may be used in an existing policy.

The authorizing entity signs a structure that contains

$$aHash \coloneqq \mathbf{H}_{aHashAlg}(approvedPolicy \,||\, policyRef) \quad (33)$$

The *aHashAlg* is required to be the *nameAlg* of the key used to sign the *aHash*. The *aHash* value is then signed (symmetric or asymmetric) by *keySign*. That signature is then checked by the TPM in 20.1 TPM2_VerifySignature() which produces a ticket by

$$\mathbf{HMAC}(proof, (\text{TPM_ST_VERIFIED} \,||\, aHash \,||\, keySign \rightarrow Name)) \quad (34)$$

NOTE 1 The reason for the validation is because of the expectation that the policy will be used multiple times and it is more efficient to check a ticket than to load an object each time to check a signature.

The ticket is then used in TPM2_PolicyAuthorize() to validate the parameters.

The *keySign* parameter is required to be a valid object name using nameAlg other than TPM_ALG_NULL. If the first two octets of *keySign* are not a valid hash algorithm, the TPM shall return TPM_RC_HASH. If the remainder of the Name is not the size of the indicated digest, the TPM shall return TPM_RC_SIZE.

The TPM validates that the *approvedPolicy* matches the current value of *policySession→policyDigest* and if not, shall return TPM_RC_VALUE.

The TPM then validates that the parameters to TPM2_PolicyAuthorize() match the values used to generate the ticket. If so, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then it will update *policySession→policyDigest* with **PolicyUpdate**() (see 23.2.3).

$$\mathbf{PolicyUpdate}(\text{TPM_CC_PolicyAuthorize}, keySign, policyRef) \quad (35)$$

If the ticket is not valid, the TPM shall return TPM_RC_POLICY.

If *policySession* is a trial session, *policySession→policyDigest* is extended as if the ticket is valid without actual verification.

NOTE 2 The unmarshaling process requires that a proper TPMT_TK_VERIFIED be provided for *checkTicket* but it may be a NULL Ticket. A NULL ticket is useful in a trial policy, where the caller uses the TPM to perform policy calculations but does not have a valid authorization ticket.

```

23.17 TPM2_PolicyAuthValue

23.17.1 General Description

This command allows a policy to be bound to the authorization value of the authorized entity.

When this command completes successfully, *policySession→isAuthValueNeeded* is SET to indicate that the *authValue* will be included in *hmacKey* when the authorization HMAC is computed for the command being authorized using this session. Additionally, *policySession→isPasswordNeeded* will be CLEAR.

NOTE If a policy does not use this command, then the *hmacKey* for the authorized command would only use *sessionKey.* If *sessionKey* is not present, then the *hmacKey* is an Empty Buffer and no HMAC would be computed.

If successful, *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyAuthValue}) \quad (36)$$

23.18 TPM2_PolicyPassword

23.18.1 General Description

This command allows a policy to be bound to the authorization value of the authorized object.

When this command completes successfully, *policySession→isPasswordNeeded* is SET to indicate that *authValue* of the authorized object will be checked when the session is used for authorization. The caller will provide the *authValue* in clear text in the *hmac* parameter of the authorization. The comparison of *hmac* to *authValue* is performed as if the authorization is a password.

NOTE 1 The parameter field in the policy session where the authorization value is provided is called *hmac*. If TPM2_PolicyPassword() is part of the sequence, then the field will contain a password and not an HMAC.

If successful, *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \,||\, \text{TPM_CC_PolicyAuthValue}) \quad (37)$$

NOTE 2 This is the same extend value as used with TPM2_PolicyAuthValue so that the evaluation may be done using either an HMAC or a password with no change to the *authPolicy* of the object. The reason that two commands are present is to indicate to the TPM if the *hmac* field in the authorization will contain an HMAC or a password value.

When this command is successful, *policySession→isAuthValueNeeded* will be CLEAR.

23.20 TPM2_PolicyNvWritten

23.20.1 General Description

This command allows a policy to be bound to the TPMA_NV_WRITTEN attributes. This is a deferred assertion. Values are stored in the policy session context and checked when the policy is used for authorization.

If *policySession→checkNVWritten* is CLEAR, it is SET and *policySession→nvWrittenState* is set to *writtenSet*. If *policySession→checkNVWritten* is SET, the TPM will return TPM_RC_VALUE if *policySession→nvWrittenState* and *writtenSet* are not the same.

If the TPM does not return an error, it will update *policySession→policyDigest* by

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyNvWritten} \mathbin{||} writtenSet) \quad (38)$$

When the policy session is used to authorize a command, the TPM will fail the command if *policySession→checkNVWritten* is SET and *nvIndex→attributes→TPMA_NV_WRITTEN does not match policySession→nvWrittenState.*

NOTE 1 A typical use case is a simple policy for the first write during manufacturing provisioning that would require TPMA_NV_WRITTEN CLEAR and a more complex policy for later use that would require TPMA_NV_WRITTEN SET.

NOTE 2 When an Index is written, it has a different authorization name than an Index that has not been written. It is possible to use this change in the NV Index to create a write-once Index.

52 }
53 #endif // CC_PolicyNvWritten
```

23.21 TPM2_PolicyTemplate

23.21.1 General Description

This command allows a policy to be bound to a specific creation template. This is most useful for an object creation command such as TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded().

The *templateHash* parameter should contain the digest of the template that will be required for the *inPublic* parameter of an Object creation command.

If *policySession→isTemplateHash* is SET and *policySession→cpHash* is not equal to *templateHash,* the TPM shall return TPM_RC_VALUE.

NOTE 1 Revision 01.38 of this specification permitted the TPM to return TPM_RC_CPHASH.

Otherwise, if *policySession→cpHash* is already set, the TPM shall return TPM_RC_CPHASH.

NOTE 2 Revision 01.38 of this specification permitted the TPM to return TPM_RC_VALUE.

If the size of *templateHash* is not the size of *policySession→policyDigest*, the TPM shall return TPM_RC_SIZE. Otherwise, *policySession→cpHash* is set to *templateHash*.

NOTE 3 The digest calculation includes the TPM2B buffer but not the TPM2B size.

If this command completes successfully, the *cpHash* of the authorized command will not be used for validation. Only the digest of the *inPublic* parameter will be used.

NOTE 4 This allows the space normally used to hold *policySession→cpHash* to be used for *policySession→templateHash* instead.

The *policySession→policyDigest* will be updated with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyTemplate} \mathbin{||} templateHash) \qquad (39)$$

23.22 TPM2_PolicyAuthorizeNV

23.22.1 General Description

This command provides a capability that is the equivalent of a revocable policy. With TPM2_PolicyAuthorize(), the authorization ticket never expires, so the authorization may not be withdrawn. With this command, the approved policy is kept in an NV Index location so that the policy may be changed as needed to render the old policy unusable.

NOTE 1 This command is useful for Objects but of limited value for other policies that are persistently stored in TPM NV, such as the OwnerPolicy.

An authorization session providing authorization to read the NV Index shall be provided.

The authorization to read the NV Index must succeed even if *policySession* is a trial policy session.

If *policySession* is a trial policy session, the TPM will update *policySession→policyDigest* as shown in equation (40) below and return TPM_RC_SUCCESS. It will not perform any further validation. The remainder of this general description would apply only if *policySession* is not a trial policy session.

NOTE 2 If read access is controlled by policy, the policy should include a branch that authorizes a TPM2_PolicyAuthorizeNV().

If TPMA_NV_WRITTEN is not SET in the Index referenced by *nvIndex*, the TPM shall return TPM_RC_NV_UNINITIALIZED. If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

The *dataSize* of the NV Index referenced by *nvIndex* is required to be at least large enough to hold a properly formatted TPMT_HA (TPM_RC_INSUFFICIENT).

NOTE 3 A TPMT_HA contains a TPM_ALG_ID followed a digest that is consistent in size with the hash algorithm indicated by the TPM_ALG_ID.

It is an error (TPM_RC_HASH) if the first two octets of the Index are not a TPM_ALG_ID for a hash algorithm implemented on the TPM or if the indicated hash algorithm does not match *policySession→authHash*.

NOTE 4 The TPM_ALG_ID is stored in the first two octets in big endian format.

The TPM will compare *policySession→policyDigest* to the contents of the NV Index, starting at the first octet after the TPM_ALG_ID (the third octet) and return TPM_RC_VALUE if they are not the same.

NOTE 5 If the Index does not contain enough bytes for the compare, then TPM_RC_INSUFFICENT is generated as indicated above.

NOTE 6 The *dataSize* of the Index may be larger than is required for this command. This permits the Index to include metadata.

If the comparison is successful, the TPM will reset *policySession→policyDigest* to a Zero Digest. Then it will update *policySession→policyDigest* with

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_PolicyAuthorizeNV} \mathbin{||} nvIndex{\rightarrow}Name) \quad (40)$$

24 Hierarchy Commands

24.1 TPM2_CreatePrimary

24.1.1 General Description

This command is used to create a Primary Object under one of the Primary Seeds or a Temporary Object under TPM_RH_NULL. The command uses a TPM2B_PUBLIC as a template for the object to be created. The size of the *unique* field shall not be checked for consistency with the other object parameters. The command will create and load a Primary Object. The sensitive area is not returned.

NOTE 1 Since the sensitive data is not returned, the key cannot be reloaded. It can either be made persistent or it can be recreated.

NOTE 2 For interoperability, the *unique* field should not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail.

NOTE 3 An Empty Buffer is a legal *unique* field value.

EXAMPLE 1 A TPM_ALG_RSA object with a *keyBits* of 2048 in the objects parameters should have a *unique* field that is no larger than 256 bytes.

EXAMPLE 2 A TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object should have a *unique* field this is no larger than the digest produced by the object's *nameAlg*.

Any type of object and attributes combination that is allowed by TPM2_Create() may be created by this command. The constraints on templates and parameters are the same as TPM2_Create() except that a Primary Storage Key and a Temporary Storage Key are not constrained to use the algorithms of their parents.

For setting of the attributes of the created object, *fixedParent*, *fixedTPM*, decrypt, and restricted are implied to be SET in the parent (a Permanent Handle). The remaining attributes are implied to be CLEAR.

The TPM will derive the object from the Primary Seed indicated in *primaryHandle* using an approved KDF. All of the bits of the template are used in the creation of the Primary Key. Methods for creating a Primary Object from a Primary Seed are described in TPM 2.0 Part 1 and implemented in TPM 2.0 Part 4.

If this command is called multiple times with the same *inPublic* parameter, *inSensitive.data*, and Primary Seed, the TPM shall produce the same Primary Object.

NOTE 4 If the Primary Seed is changed, the Primary Objects generated with the new seed shall be statistically unique even if the parameters of the call are the same.

This command requires authorization. Authorization for a Primary Object attached to the Platform Primary Seed (PPS) shall be provided by *platformAuth* or *platformPolicy*. Authorization for a Primary Object attached to the Storage Primary Seed (SPS) shall be provided by *ownerAuth* or *ownerPolicy*. Authorization for a Primary Key attached to the Endorsement Primary Seed (EPS) shall be provided by *endorsementAuth* or *endorsementPolicy*.

24.2 TPM2_HierarchyControl

24.2.1 General Description

This command enables and disables use of a hierarchy and its associated NV storage. The command allows *phEnable*, *phEnableNV*, *shEnable*, and *ehEnable* to be changed when the proper authorization is provided.

This command may be used to CLEAR *phEnable* and *phEnableNV* if *platformAuth/platformPolicy* is provided. *phEnable* may not be SET using this command.

This command may be used to CLEAR *shEnable* if either *platformAuth/platformPolicy* or *ownerAuth/ownerPolicy* is provided. *shEnable* may be SET if *platformAuth*/*platformPolicy* is provided.

This command may be used to CLEAR *ehEnable* if either *platformAuth*/*platformPolicy* or *endorsementAuth*/*endorsementPolicy* is provided. *ehEnable* may be SET if *platformAuth*/*platformPolicy* is provided.

When this command is used to CLEAR *phEnable*, *shEnable*, or *ehEnable*, the TPM will disable use of any persistent entity associated with the disabled hierarchy and will flush any transient objects associated with the disabled hierarchy.

When this command is used to CLEAR *shEnable,* the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE CLEAR (indicating that the NV Index was defined using Owner Authorization). As long as *shEnable* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE CLEAR.

When this command is used to CLEAR *phEnableNV*, the TPM will disable access to any NV index that has TPMA_NV_PLATFORMCREATE SET (indicating that the NV Index was defined using Platform Authorization). As long as *phEnableNV* is CLEAR, the TPM will return an error in response to any command that attempts to operate upon an NV index that has TPMA_NV_PLATFORMCREATE SET.

24.3 TPM2_SetPrimaryPolicy

24.3.1 General Description

This command allows setting of the authorization policy for the lockout (*lockoutPolicy*), the platform hierarchy (*platformPolicy*), the storage hierarchy (*ownerPolicy*), and the endorsement hierarchy (*endorsementPolicy*). On TPMs implementing Authenticated Countdown Timers (ACT), this command may also be used to set the authorization policy for an ACT.

The command requires an authorization session. The session shall use the current *authValue* or satisfy the current *authPolicy* for the referenced hierarchy, or the ACT.

The policy that is changed is the policy associated with *authHandle*.

If the enable associated with *authHandle* is not SET, then the associated authorization values (*authValue* or *authPolicy*) may not be used, and the TPM returns TPM_RC_HIERARCHY.

When *hashAlg* is not TPM_ALG_NULL, if the size of *authPolicy* is not consistent with the hash algorithm, the TPM returns TPM_RC_SIZE.

24.4 TPM2_ChangePPS

24.4.1 General Description

This replaces the current platform primary seed (PPS) with a value from the RNG and sets *platformPolicy* to the default initialization value (the Empty Buffer).

NOTE 1 A policy that is the Empty Buffer can match no policy.

NOTE 2 Platform Authorization is not changed.

All resident transient and persistent objects in the Platform hierarchy are flushed.

Saved contexts in the Platform hierarchy that were created under the old PPS will no longer be able to be loaded.

The policy hash algorithm for PCR is reset to TPM_ALG_NULL.

This command does not clear any NV Index values.

NOTE 3 Index values belonging to the Platform are preserved because the indexes may have configuration information that will be the same after the PPS changes. The Platform may remove the indexes that are no longer needed using TPM2_NV_UndefineSpace().

This command requires Platform Authorization.

24.5 TPM2_ChangeEPS

24.5.1 General Description

This replaces the current endorsement primary seed (EPS) with a value from the RNG and sets the Endorsement hierarchy controls to their default initialization values: *ehEnable* is SET, *endorsementAuth* and *endorsementPolicy* are both set to the Empty Buffer. It will flush any resident objects (transient or persistent) in the Endorsement hierarchy and not allow objects in the hierarchy associated with the previous EPS to be loaded.

NOTE In the reference implementation, *ehProof* is a non-volatile value from the RNG. It is allowed that the *ehProof* be generated by a KDF using both the EPS and SPS as inputs. If generated with a KDF, the ehProof can be generated on an as-needed basis or made a non-volatile value.

This command requires Platform Authorization.

24.6 TPM2_Clear

24.6.1 General Description

This command removes all TPM context associated with a specific Owner.

The clear operation will:

- flush resident objects (persistent and volatile) in the Storage and Endorsement hierarchies;
- delete any NV Index with TPMA_NV_PLATFORMCREATE == CLEAR;
- change the storage primary seed (SPS) to a new value from the TPM's random number generator (RNG),
- change *shProof* and *ehProof*,

NOTE 1 The proof values may be set from the RNG or derived from the associated new Primary Seed. If derived from the Primary Seeds, the derivation of *ehProof* shall use both the SPS and EPS. The computation shall use the SPS as an HMAC key and the derived value may then be a parameter in a second HMAC in which the EPS is the HMAC key. The reference design uses values from the RNG.

- SET *shEnable* and *ehEnable*;
- set *ownerAuth*, *endorsementAuth*, and *lockoutAuth* to the Empty Buffer;
- set *ownerPolicy, endorsementPolicy,* and *lockoutPolicy* to the Empty Buffer;
- set *Clock* to zero;
- set *resetCount* to zero;
- set *restartCount* to zero; and
- set *Safe* to YES.
- increment *pcrUpdateCounter*

NOTE 2 This permits an application to create a policy session that is invalidated on TPM2_Clear. The policy needs, ideally as the first term, TPM2_PolicyPCR(). The session is invalidated even if the PCR selection is empty.

This command requires Platform Authorization or Lockout Authorization. If TPM2_ClearControl() has disabled this command, the TPM shall return TPM_RC_DISABLED.

If this command is authorized using *lockoutAuth*, the HMAC in the response shall use the new *lockoutAuth* value (that is, the Empty Buffer) when computing the response HMAC.

24.7 TPM2_ClearControl

24.7.1 General Description

TPM2_ClearControl() disables and enables the execution of TPM2_Clear().

The TPM will SET the TPM's TPMA_PERMANENT.*disableClear* attribute if *disable* is YES and will CLEAR the attribute if *disable* is NO. When the attribute is SET, TPM2_Clear() may not be executed.

NOTE This is to simplify the logic of TPM2_Clear(). TPM2_ClearControl() can be called using Platform Authorization to CLEAR the *disableClear* attribute and then execute TPM2_Clear().

Lockout Authorization may be used to SET *disableClear* but not to CLEAR it.

Platform Authorization may be used to SET or CLEAR *disableClear*.

24.8 TPM2_HierarchyChangeAuth

24.8.1 General Description

This command allows the authorization secret for a hierarchy or lockout to be changed using the current authorization value as the command authorization.

If *authHandle* is TPM_RH_PLATFORM, then *platformAuth* is changed. If *authHandle* is TPM_RH_OWNER, then o*wnerAuth* is changed. If *authHandle* is TPM_RH_ENDORSEMENT, then e*ndorsementAuth* is changed. If *authHandle* is TPM_RH_LOCKOUT, then *lockoutAuth* is changed. The HMAC in the response shall use the new authorization value when computing the response HMAC.

If *authHandle* is TPM_RH_PLATFORM, then Physical Presence may need to be asserted for this command to succeed (see 26.2, *TPM2_PP_Commands*).

The authorization value may be no larger than the digest produced by the hash algorithm used for context integrity.

EXAMPLE If SHA384 is used in the computation of the integrity values for saved contexts, then the largest authorization value is 48 octets.

25 Dictionary Attack Functions

25.1 Introduction

A TPM is required to have support for logic that will help prevent a dictionary attack on an authorization value. The protection is provided by a counter that increments when a password authorization or an HMAC authorization fails. When the counter reaches a predefined value, the TPM will not accept, for some time interval, further requests that require authorization and the TPM is in Lockout mode. While the TPM is in Lockout mode, the TPM will return TPM_RC_LOCKOUT if the command requires use of an object's or Index's *authValue* unless the authorization applies to an entry in the Platform hierarchy.

NOTE 1 Authorizations for objects and NV Index values in the Platform hierarchy are never locked out. However, a command that requires multiple authorizations will not be accepted when the TPM is in Lockout mode unless all of the authorizations reference objects and indexes in the Platform hierarchy.

If the TPM is continuously powered for the duration of *newRecoveryTime* and no authorization failures occur, the authorization failure counter will be decremented by one. This property is called "self-healing." Self-healing shall not cause the count of failed attempts to decrement below zero.

The count of failed attempts, the lockout interval, and self-healing interval are settable using TPM2_DictionaryAttackParameters(). The lockout parameters and the current value of the lockout counter can be read with TPM2_GetCapability().

Dictionary attack protection does not apply to an entity associated with a permanent handle (handle type == TPM_HT_PERMANENT) other than TPM_RH_LOCKOUT

25.2 TPM2_DictionaryAttackLockReset

25.2.1 General Description

This command cancels the effect of a TPM lockout due to a number of successive authorization failures. If this command is properly authorized, the lockout counter is set to zero.

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval (set using TPM2_DictionaryAttackParameters().

25.3 TPM2_DictionaryAttackParameters

25.3.1 General Description

This command changes the lockout parameters.

The command requires Lockout Authorization.

The timeout parameters (*newRecoveryTime* and *lockoutRecovery*) indicate values that are measured with respect to the *Time* and not *Clock*.

NOTE Use of *Time* means that the TPM shall be continuously powered for the duration of a timeout.

If *newRecoveryTime* is zero, then DA protection is disabled. Authorizations are checked but authorization failures will not cause the TPM to enter lockout.

If *newMaxTries* is zero, the TPM will be in lockout and use of DA protected entities will be disabled.

If *lockoutRecovery* is zero, then the recovery interval is _TPM_Init followed by TPM2_Startup().

Only one *lockoutAuth* authorization failure is allowed for this command during a *lockoutRecovery* interval.

26 Miscellaneous Management Functions

26.1 Introduction

This clause contains commands that do not logically group with any other commands.

26.2 TPM2_PP_Commands

26.2.1 General Description

This command is used to determine which commands require assertion of Physical Presence (PP) in addition to *platformAuth*/*platformPolicy*.

This command requires that *auth* is TPM_RH_PLATFORM and that Physical Presence be asserted.

After this command executes successfully, the commands listed in *setList* will be added to the list of commands that require that Physical Presence be asserted when the handle associated with the authorization is TPM_RH_PLATFORM. The commands in *clearList* will no longer require assertion of Physical Presence in order to authorize a command.

If a command is not in either list, its state is not changed. If a command is in both lists, then it will no longer require Physical Presence (for example, *setList* is processed first).

Only commands with handle types of TPMI_RH_PLATFORM, TPMI_RH_PROVISION, TPMI_RH_CLEAR, or TPMI_RH_HIERARCHY can be gated with Physical Presence. If any other command is in either list, it is discarded.

When a command requires that Physical Presence be provided, then Physical Presence shall be asserted for either an HMAC or a Policy authorization.

NOTE 1 Physical Presence may be made a requirement of any policy.

NOTE 2 If the TPM does not implement this command, the command list is vendor specific. A platform-specific specification may require that the command list be initialized in a specific way.

TPM2_PP_Commands() always requires assertion of Physical Presence.

26.3 TPM2_SetAlgorithmSet

26.3.1 General Description

This command allows the platform to change the set of algorithms that are used by the TPM. The *algorithmSet* setting is a vendor-dependent value.

If the changing of the algorithm set results in a change of the algorithms of PCR banks, then the TPM will need to be reset (_TPM_Init and TPM2_Startup(TPM_SU_CLEAR)) before the new PCR settings take effect. After this command executes successfully, if *startupType* in the next TPM2_Startup() is not TPM_SU_CLEAR, the TPM shall return TPM_RC_VALUE and may enter Failure mode.

Other than PCR, when an algorithm is no longer supported, the behavior of this command is vendor-dependent.

EXAMPLE Entities may remain resident. Persistent objects, transient objects, or sessions may be flushed. NV Indexes may be undefined. Policies may be erased.

NOTE The reference implementation does not have support for this command. In particular, it does not support use of this command to selectively disable algorithms. Proper support would require modification of the unmarshaling code so that each time an algorithm is unmarshaled, it would be verified as being enabled.

27 Field Upgrade

27.1 Introduction

This clause contains the commands for managing field upgrade of the firmware in the TPM. The field upgrade scheme may be used for replacement or augmentation of the firmware installed in the TPM.

EXAMPLE 1 If an algorithm is found to be flawed, a patch of that algorithm might be installed using the firmware upgrade process. The patch might be a replacement of a portion of the code or a complete replacement of the firmware.

EXAMPLE 2 If an additional set of ECC parameters is needed, the firmware process may be used to add the parameters to the TPM data set.

The field upgrade process uses two commands (TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData()). TPM2_FieldUpgradeStart() validates that a signature on the provided digest is from the TPM manufacturer and that proper authorization is provided using *platformPolicy*.

NOTE 1 The *platformPolicy* for field upgraded is defined by the PM and may include requirements that the upgrade be signed by the PM or the TPM owner and include any other constraints that are desired by the PM.

If the proper authorization is given, the TPM will retain the signed digest and enter the Field Upgrade mode (FUM). While in FUM, the TPM will accept TPM2_FieldUpgradeData() commands. It may accept other commands if it is able to complete them using the previously installed firmware. Otherwise, it will return TPM_RC_UPGRADE.

Each block of the field upgrade shall contain the digest of the next block of the field upgrade data. That digest shall be included in the digest of the previous block. The digest of the first block is signed by the TPM manufacturer. That signature and first block digest are the parameters for TPM2_FieldUpgradeStart(). The digest is saved in the TPM as the required digest for the next field upgrade data block and as the identifier of the field upgrade sequence.

For each field upgrade data block that is sent to the TPM by TPM2_FieldUpgradeData(), the TPM shall validate that the digest matches the required digest and if not, shall return TPM_RC_VALUE. The TPM shall extract the digest of the next expected block and return that value to the caller, along with the digest of the first data block of the update sequence.

The system may attempt to abandon the firmware upgrade by using a zero-length buffer in TPM2_FieldUpdateData(). If the TPM is able to resume operation using the firmware present when the upgrade started, then the TPM will indicate that it has abandon the update by setting the digest of the next block to the Empty Buffer. If the TPM cannot abandon the update, it will return the expected next digest.

The system may also attempt to abandon the update because of a power interruption. If the TPM is able to resume normal operations, then it will respond normally to TPM2_Startup(). If the TPM is not able to resume normal operations, then it will respond to any command but TPM2_FieldUpgradeData() with TPM_RC_UPGRADE.

After a _TPM_Init, system software may not be able to resume the field upgrade that was in process when the power interruption occurred. In such case, the TPM firmware may be reset to one of two other values:

- the original firmware that was installed at the factory (“initial firmware”); or
- the firmware that was in the TPM when the field upgrade process started (“previous firmware”).

The TPM retains the digest of the first block for these firmware images and checks to see if the first block after _TPM_Init matches either of those digests. If so, the firmware update process restarts and the original firmware may be loaded.

 Copyright © TCG 2006-2020

NOTE 2 The TPM is required to accept the previous firmware as either a vendor-provided update or as recovered from the TPM using TPM2_FirmwareRead().

When the last block of the firmware upgrade is loaded into the TPM (indicated to the TPM by data in the data block in a TPM vendor-specific manner), the TPM will complete the upgrade process. If the TPM is able to resume normal operations without a reboot, it will set the hash algorithm of the next block to TPM_ALG_NULL and return TPM_RC_SUCCESS. If a reboot is required, the TPM shall return TPM_RC_REBOOT in response to the last TPM2_FieldUpgradeData() and all subsequent TPM commands until a _TPM_Init is received.

NOTE 3 Because no additional data is allowed when the response code is not TPM_RC_SUCCESS, the TPM returns TPM_RC_SUCCESS for all calls to TPM2_FieldUpgradeData() except the last. In this manner, the TPM is able to indicate the digest of the next block. If a _TPM_Init occurs while the TPM is in FUM, the next block may be the digest for the first block of the original firmware. If it is not, then the TPM will not accept the original firmware until the next _TPM_Init when the TPM is in FUM.

During the field upgrade process, either the one specified in this clause or a vendor proprietary field upgrade process, the TPM should preserve:

- Primary Seeds;
- Hierarchy *authValue*, *authPolicy*, and *proof* values;
- Lockout *authValue* and authorization failure count values;
- PCR authValue and authPolicy values;
- NV Index allocations and contents;
- Persistent object allocations and contents; and
- Clock.

NOTE 4 A platform manufacturer may provide a means to change preserved data to accommodate a case where a field upgrade fixes a flaw that might have compromised TPM secrets.

27.2 TPM2_FieldUpgradeStart

27.2.1 General Description

This command uses *platformPolicy* and a TPM Vendor Authorization Key to authorize a Field Upgrade Manifest.

If the signature checks succeed, the authorization is valid and the TPM will accept TPM2_FieldUpgradeData().

This signature is checked against the loaded key referenced by *keyHandle*. This key will have a Name that is the same as a value that is part of the TPM firmware data. If the signature is not valid, the TPM shall return TPM_RC_SIGNATURE.

NOTE A loaded key is used rather than a hard-coded key to reduce the amount of memory needed for this key data in case more than one vendor key is needed.

27.3 TPM2_FieldUpgradeData

27.3.1 General Description

This command will take the actual field upgrade image to be installed on the TPM. The exact format of *fuData* is vendor-specific. This command is only possible following a successful TPM2_FieldUpgradeStart(). If the TPM has not received a properly authorized TPM2_FieldUpgradeStart(), then the TPM shall return TPM_RC_FIELDUPGRADE.

The TPM will validate that the digest of *fuData* matches an expected value. If so, the TPM may buffer or immediately apply the update. If the digest of *fuData* does not match an expected value, the TPM shall return TPM_RC_VALUE.

14 }
15 #endif
```

27.4 TPM2_FirmwareRead

27.4.1 General Description

This command is used to read a copy of the current firmware installed in the TPM.

The presumption is that the data will be returned in reverse order so that the last block in the sequence would be the first block given to the TPM in case of a failure recovery. If the TPM2_FirmwareRead sequence completes successfully, then the data provided from the TPM will be sufficient to allow the TPM to recover from an abandoned upgrade of this firmware.

To start the sequence of retrieving the data, the caller sets *sequenceNumber* to zero. When the TPM has returned all the firmware data, the TPM will return the Empty Buffer as *fuData*.

The contents of *fuData* are opaque to the caller.

NOTE 1 The caller should retain the ordering of the update blocks so that the blocks sent to the TPM have the same size and inverse order as the blocks returned by a sequence of calls to this command.

NOTE 2 Support for this command is optional even if the TPM implements TPM2_FieldUpgradeStart() and TPM2_FieldUpgradeData().

28 Context Management

28.1 Introduction

Three of the commands in this clause (TPM2_ContextSave(), TPM2_ContextLoad(), and TPM2_FlushContext()) implement the resource management described in the "Context Management" clause in TPM 2.0 Part 1.

The fourth command in this clause (TPM2_EvictControl()) is used to control the persistence of loadable objects in TPM memory. Background for this command may be found in the "Owner and Platform Evict Objects" clause in TPM 2.0 Part 1.

28.2 TPM2_ContextSave

28.2.1 General Description

This command saves a session context, object context, or sequence object context outside the TPM.

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS.

NOTE This preclusion avoids complex issues of dealing with the same session in *handle* and in the session area. While it might be possible to provide specificity, it would add unnecessary complexity to the TPM and, because this capability would provide no application benefit, use of authorization sessions for audit or encryption is prohibited.

The TPM shall encrypt and integrity protect the TPM2B_CONTEXT_SENSITIVE *context* as described in the "Context Protections" clause in TPM 2.0 Part 1.

See the “Context Data” clause in TPM 2.0 Part 2 for a description of the *context* structure in the response.

28.3 TPM2_ContextLoad

28.3.1 General Description

This command is used to reload a context that has been saved by TPM2_ContextSave().

No authorization sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in 28.2.1).

The TPM will return TPM_RC_HIERARCHY if the context is associated with a hierarchy that is disabled.

NOTE Contexts for authorization sessions and for sequence objects belong to the NULL hierarchy, which is never disabled.

See the “Context Data” clause in TPM 2.0 Part 2 for a description of the values in the *context* parameter.

If the integrity HMAC of the saved context is not valid, the TPM shall return TPM_RC_INTEGRITY.

The TPM shall perform a check on the decrypted context as described in the "Context Confidentiality Protection" clause of TPM 2.0 Part 1 and enter failure mode if the check fails.

28.4 TPM2_FlushContext

28.4.1 General Description

This command causes all context associated with a loaded object, sequence object, or session to be removed from TPM memory.

This command may not be used to remove a persistent object from the TPM. Use TPM2_EvictControl to remove a persistent object.

A session does not have to be loaded in TPM memory to have its context flushed. The saved session context associated with the indicated handle is invalidated. When flushing a session, the upper byte of the handle is ignored.

EXAMPLE A command to flush session handle 0x20000000 will flush session handle 0x03000000.

No sessions of any type are allowed with this command and tag is required to be TPM_ST_NO_SESSIONS (see note in 28.2.1).

If the handle is for a Transient Object and the handle is not associated with a loaded object, then the TPM shall return TPM_RC_HANDLE.

If the handle is for an authorization session and the handle does not reference a loaded or active session, then the TPM shall return TPM_RC_HANDLE.

NOTE *flushHandle* is a parameter and not a handle. If it were in the handle area, the TPM would validate that the context for the referenced entity is in the TPM. When a TPM2_FlushContext references a saved session context, it is not necessary for the context to be in the TPM. When the *flushHandle* is in the parameter area, the TPM does not validate that associated context is actually in the TPM.

40     }
41
42     return TPM_RC_SUCCESS;
43 }
44 #endif // CC_FlushContext
```

28.5 TPM2_EvictControl

28.5.1 General Description

This command allows certain Transient Objects to be made persistent or a persistent object to be evicted.

NOTE 1 A transient object is one that may be removed from TPM memory using either TPM2_FlushContext or TPM2_Startup(). A persistent object is not removed from TPM memory by TPM2_FlushContext() or TPM2_Startup().

If *objectHandle* is a Transient Object, then this call makes a persistent copy of the object and assigns *persistentHandle* to the persistent version of the object. If *objectHandle* is a persistent object, then the call evicts the persistent object. The call does not affect the transient object.

Before execution of TPM2_EvictControl code below, the TPM verifies that *objectHandle* references an object that is resident on the TPM and that *persistentHandle* is a valid handle for a persistent object.

NOTE 2 This requirement simplifies the unmarshaling code so that it only need check that *persistentHandle* is always a persistent object.

If *objectHandle* references a Transient Object:

a) The TPM shall return TPM_RC_ATTRIBUTES if
   1) it is in the hierarchy of TPM_RH_NULL,
   2) only the public portion of the object is loaded, or

      NOTE 3 This is for NV space efficiency. Loading an object whose private part is empty would unnecessarily consume NV resources.

   3) the *stClear* is SET in the object or in an ancestor key.
b) The TPM shall return TPM_RC_HIERARCHY if the object is not in the proper hierarchy as determined by *auth*.
   1) If *auth* is TPM_RH_PLATFORM, the proper hierarchy is the Platform hierarchy.
   2) If *auth* is TPM_RH_OWNER, the proper hierarchy is either the Storage or the Endorsement hierarchy.
c) The TPM shall return TPM_RC_RANGE if *persistentHandle* is not in the proper range as determined by *auth*.
   1) If *auth* is TPM_RH_OWNER, then *persistentHandle* shall be in the inclusive range of 81 00 00 00_{16} to 81 7F FF FF_{16}.
   2) If *auth* is TPM_RH_PLATFORM, then *persistentHandle* shall be in the inclusive range of 81 80 00 00_{16} to 81 FF FF FF_{16}.

   NOTE 4 This separation permits the platform (the platform OEM) a range of indexes that will not interfere with indexes used by the TPM owner (the OS or applications).

d) The TPM shall return TPM_RC_NV_DEFINED if a persistent object exists with the same handle as *persistentHandle*.
e) The TPM shall return TPM_RC_NV_SPACE if insufficient space is available to make the object persistent.
f) The TPM shall return TPM_RC_NV_SPACE if execution of this command will prevent the TPM from being able to hold two transient objects of any kind.

   NOTE 5 This requirement anticipates that a TPM may be implemented such that all TPM memory is non-volatile and not subject to endurance issues. In such case, there is no movement of an object

 Copyright © TCG 2006-2020

between memory of different types and it is necessary that the TPM ensure that it is always possible for the management software to move objects to/from TPM memory in order to ensure that the objects required for command execution can be context restored.

g) If the TPM returns TPM_RC_SUCCESS, the object referenced by *objectHandle* will not be flushed and both *objectHandle* and *persistentHandle* may be used to access the object.

If *objectHandle* references a persistent object:

a) The TPM shall return TPM_RC_RANGE if *objectHandle* is not in the proper range as determined by *auth*. If *auth* is TPM_RC_OWNER, *objectHandle* shall be in the inclusive range of 81 00 00 00_{16} to 81 7F FF FF_{16}. If *auth* is TPM_RC_PLATFORM, *objectHandle* may be any valid persistent object handle.

b) If objectHandle is not the same value as persistentHandle, return TPM_RC_HANDLE.

c) If the TPM returns TPM_RC_SUCCESS, *objectHandle* will be removed from persistent memory and no longer be accessible.

NOTE 5 The persistent object is not converted to a transient object, as this would prevent the immediate revocation of an object by removing it from persistent memory.

14      return TPM_RC_SUCCESS;
15  }
16  #endif // CC_ReadClock
```

29.2 TPM2_ClockSet

29.2.1 General Description

This command is used to advance the value of the TPM's *Clock*. The command will fail if *newTime* is less than the current value of *Clock* or if the new time is greater than FF FF 00 00 00 00 00 00_{16}. If both of these checks succeed, *Clock* is set to *newTime*. If either of these checks fails, the TPM shall return TPM_RC_VALUE and make no change to *Clock*.

NOTE This maximum setting would prevent *Clock* from rolling over to zero for approximately 8,000 years at the real time *Clock* update rate. If the *Clock* update rate was set so that TPM time was passing 33 percent faster than real time, it would still be more than 6,000 years before *Clock* would roll over to zero. Because *Clock* will not roll over in the lifetime of the TPM, there is no need for external software to deal with the possibility that *Clock* may wrap around.

If the value of *Clock* after the update makes the volatile and non-volatile versions of TPMS_CLOCK_INFO.*clock* differ by more than the reported update interval, then the TPM shall update the non-volatile version of TPMS_CLOCK_INFO.*clock* before returning.

This command requires Platform Authorization or Owner Authorization.

29.3 TPM2_ClockRateAdjust

29.3.1 General Description

This command adjusts the rate of advance of *Clock* and *Time* to provide a better approximation to real time.

The *rateAdjust* value is relative to the current rate and not the nominal rate of advance.

EXAMPLE 1 If this command had been called three times with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER and once with *rateAdjust* = TPM_CLOCK_COARSE_FASTER, the net effect will be as if the command had been called twice with *rateAdjust* = TPM_CLOCK_COARSE_SLOWER.

The range of adjustment shall be sufficient to allow *Clock* and *Time* to advance at real time but no more. If the requested adjustment would make the rate advance faster or slower than the nominal accuracy of the input frequency, the TPM shall return TPM_RC_VALUE.

EXAMPLE 2 If the frequency tolerance of the TPM's input clock is +/-10 percent, then the TPM will return TPM_RC_VALUE if the adjustment would make *Clock* run more than 10 percent faster or slower than nominal. That is, if the input oscillator were nominally 100 megahertz (MHz), then 1 millisecond (ms) would normally take 100,000 counts. The update *Clock* should be adjustable so that 1 ms is between 90,000 and 110,000 counts.

The interpretation of “fine” and “coarse” adjustments is implementation-specific.

The nominal rate of advance for *Clock* and *Time* shall be accurate to within 15 percent. That is, with no adjustment applied, *Clock* and *Time* shall be advanced at a rate within 15 percent of actual time.

NOTE If the adjustments are incorrect, it will be possible to make the difference between advance of *Clock/Time* and real time to be as much as 1.15^2 or ~1.33.

Changes to the current *Clock* update rate adjustment need not be persisted across TPM power cycles.

30 Capability Commands

30.1 Introduction

The TPM has numerous values that indicate the state, capabilities, and properties of the TPM. These values are needed for proper management of the TPM. The TPM2_GetCapability() command is used to access these values.

TPM2_GetCapability() allows reporting of multiple values in a single call. The values are grouped according to type.

NOTE TPM2_TestParms()is used to determine if a TPM supports a particular combination of algorithm parameters

30.2 TPM2_GetCapability

30.2.1 General Description

This command returns various information regarding the TPM and its current state.

The *capability* parameter determines the category of data returned. The *property* parameter selects the first value of the selected category to be returned. If there is no property that corresponds to the value of *property*, the next higher value is returned, if it exists.

EXAMPLE 1 The list of handles of transient objects currently loaded in the TPM may be read one at a time. On the first read, set the property to TRANSIENT_FIRST and *propertyCount* to one. If a transient object is present, the lowest numbered handle is returned and *moreData* will be YES if transient objects with higher handles are loaded. On the subsequent call, use returned handle value plus 1 in order to access the next higher handle.

The *propertyCount* parameter indicates the number of capabilities in the indicated group that are requested. The TPM will return no more than the number of requested values (*propertyCount*) or until the last property of the requested type has been returned.

NOTE 1 The type of the capability is derived from a combination of *capability* and *property*.

NOTE 2 If the *property* selects an unimplemented property, the next higher implemented property is returned.

When all of the properties of the requested type have been returned, the *moreData* parameter in the response will be set to NO. Otherwise, it will be set to YES.

NOTE 3 The *moreData* parameter will be YES if there are more properties even if the requested number of capabilities has been returned.

The TPM is not required to return more than one value at a time. It is not required to provide the same number of values in response to subsequent requests.

EXAMPLE 2 A TPM may return 4 properties in response to a TPM2_GetCapability(*capability* = TPM_CAP_TPM_PROPERTY, *property* = TPM_PT_MANUFACTURER, *propertyCount* = 8) and for a latter request with the same parameters, the TPM may return as few as one and as many as 8 values.

When the TPM is in Failure mode, a TPM is required to allow use of this command for access of the following capabilities:

 Copyright © TCG 2006-2020

- TPM_PT_MANUFACTURER
- TPM_PT_VENDOR_STRING_1
- TPM_PT_VENDOR_STRING_2 (NOTE 4)
- TPM_PT_VENDOR_STRING_3 (NOTE 4)
- TPM_PT_VENDOR_STRING_4 (NOTE 4)
- TPM_PT_VENDOR_TPM_TYPE
- TPM_PT_FIRMWARE_VERSION_1
- TPM_PT_FIRMWARE_VERSION_2

NOTE 4 If the vendor string does not require one of these values, the property type does not need to exist.

A vendor may optionally allow the TPM to return other values.

If in Failure mode and a capability is requested that is not available in Failure mode, the TPM shall return no value.

EXAMPLE 3 Assume the TPM is in Failure mode and the TPM only supports reporting of the minimum required set of properties (the limited subset of TPML_TAGGED_TPM_PROPERTY values). If a TPM2_GetCapability is received requesting a capability that has a property type value greater than TPM_PT_FIRMWARE_VERSION_2, the TPM may return a zero length list with the moreData parameter set to NO or return the property TPM_PT_FIRMWARE_VERSION_2. If the property type is less than TPM_PT_MANUFACTURER, the TPM will return properties beginning with TPM_PT_MANUFACTURER.

In Failure mode, *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

The capability categories and the types of the return values are:

capability	***property***	**Return Type**
TPM_CAP_ALGS	TPM_ALG_ID(1)	TPML_ALG_PROPERTY
TPM_CAP_HANDLES	TPM_HANDLE	TPML_HANDLE
TPM_CAP_COMMANDS	TPM_CC	TPML_CCA
TPM_CAP_PP_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_AUDIT_COMMANDS	TPM_CC	TPML_CC
TPM_CAP_PCRS	Reserved	TPML_PCR_SELECTION
TPM_CAP_TPM_PROPERTIES	TPM_PT	TPML_TAGGED_TPM_PROPERTY
TPM_CAP_PCR_PROPERTIES	TPM_PT_PCR	TPML_TAGGED_PCR_PROPERTY
TPM_CAP_ECC_CURVES	TPM_ECC_CURVE(1)	TPML_ECC_CURVE
TPM_CAP_AUTH_POLICIES (3)	TPM_HANDLE(2)	TPML_TAGGED_POLICY
TPM_CAP_ACT(4)	TPM_HANDLE(2)	TPML_ACT_DATA
TPM_CAP_VENDOR_PROPERTY	manufacturer specific	manufacturer-specific values
NOTES: (1) The TPM_ALG_ID or TPM_ECC_CURVE is cast to a UINT32 (2) The TPM will return TPM_RC_VALUE if the handle does not reference the range for permanent handles. (3) TPM_CAP_AUTH_POLICIES was added in revision 01.32. (4) TPM_CAP_ACT was added in revision 01.56.		

 Copyright © TCG 2006-2020

- TPM_CAP_ALGS – Returns a list of TPMS_ALG_PROPERTIES. Each entry is an algorithm ID and a set of properties of the algorithm.
- TPM_CAP_HANDLES – Returns a list of all of the handles within the handle range of the *property* parameter. The range of the returned handles is determined by the handle type (the most-significant octet (MSO) of the *property)*. Any of the defined handle types is allowed

EXAMPLE 4 If the MSO of *property* is TPM_HT_NV_INDEX, then the TPM will return a list of NV Index values.

EXAMPLE 5 If the MSO of property is TPM_HT_PCR, then the TPM will return a list of PCR.

- For this capability, use of TPM_HT_LOADED_SESSION and TPM_HT_SAVED_SESSION is allowed. Requesting handles with a handle type of TPM_HT_LOADED_SESSION will return handles for loaded sessions. The returned handle values will have a handle type of either TPM_HT_HMAC_SESSION or TPM_HT_POLICY_SESSION. If saved sessions are requested, all returned values will have the TPM_HT_HMAC_SESSION handle type because the TPM does not track the session type of saved sessions.

NOTE 5 TPM_HT_LOADED_SESSION and TPM_HT_HMAC_SESSION have the same value, as do TPM_HT_SAVED_SESSION and TPM_HT_POLICY_SESSION. It is not possible to request that the TPM return a list of loaded HMAC sessions without including the policy sessions.

- TPM_CAP_COMMANDS – Returns a list of the command attributes for all of the commands implemented in the TPM, starting with the TPM_CC indicated by the *property* parameter. If vendor specific commands are implemented, the vendor-specific command attribute with the lowest *commandIndex*, is returned after the non-vendor-specific (base) command.

NOTE 6 The type of the property parameter is a TPM_CC while the type of the returned list is TPML_CCA.

- TPM_CAP_PP_COMMANDS – Returns a list of all of the commands currently requiring Physical Presence for confirmation of platform authorization. The list will start with the TPM_CC indicated by *property*.
- TPM_CAP_AUDIT_COMMANDS – Returns a list of all of the commands currently set for command audit.
- TPM_CAP_PCRS – Returns the current allocation of PCR in a TPML_PCR_SELECTION. The *property* parameter shall be zero. The TPM will always respond to this command with the full PCR allocation and *moreData* will be NO.

  The TPML_PCR_SELECTION must include a TPMS_PCR_SELECTION for each PCR bank in which there is at least one allocated PCR. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented PCR bank. The TPML_PCR_SELECTION may return a TPMS_PCR_SELECTION for each implemented hash algorithm.
- TPM_CAP_TPM_PROPERTIES – Returns a list of tagged properties. The tag is a TPM_PT and the property is a 32-bit value. The properties are returned in groups. Each property group is on a 256-value boundary (that is, the boundary occurs when the TPM_PT is evenly divisible by 256). The TPM will only return values in the same group as the *property* parameter in the command.
- TPM_CAP_PCR_PROPERTIES – Returns a list of tagged PCR properties. The tag is a TPM_PT_PCR and the property is a TPMS_PCR_SELECT.

  The input command property is a TPM_PT_PCR (see TPM 2.0 Part 2 for PCR properties to be requested) that specifies the first property to be returned. If propertyCount is greater than 1, the list of properties begins with that property and proceeds in TPM_PT_PCR sequence.

  Each item in the list is a TPMS_PCR_SELECT structure that contains a bitmap of all PCR.

NOTE 7 A PCR index in all banks (all hash algorithms) has the same properties, so the hash algorithm is not specified here.

 Copyright © TCG 2006-2020

- TPM_CAP_TPM_ECC_CURVES – Returns a list of ECC curve identifiers currently available for use in the TPM.
- TPM_CAP_AUTH_POLICIES - Returns a list of tagged policies reporting the authorization policies for the permanent handles.
- TPM_CAP_ACT – Returns a list of TPMS_ACT_DATA, each of which contains the handle for the ACT, the remaining time before it expires, and the ACT attributes.

The *moreData* parameter will have a value of YES if there are more values of the requested type that were not returned.

If no next capability exists, the TPM will return a zero-length list and *moreData* will have a value of NO.

30.2.2 Command and Response

Table 208 — TPM2_GetCapability Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_GetCapability
TPM_CAP	capability	group selection; determines the format of the response
UINT32	property	further definition of information
UINT32	propertyCount	number of properties of the indicated type to return

Table 209 — TPM2_GetCapability Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	
TPMI_YES_NO	moreData	flag to indicate if there are more values of this type
TPMS_CAPABILITY_DATA	capabilityData	the capability data

30.3 TPM2_TestParms

30.3.1 General Description

This command is used to check to see if specific combinations of algorithm parameters are supported.

The TPM will unmarshal the provided TPMT_PUBLIC_PARMS. If the parameters unmarshal correctly, then the TPM will return TPM_RC_SUCCESS, indicating that the parameters are valid for the TPM. The TPM will return the appropriate unmarshaling error if a parameter is not valid.

31 Non-volatile Storage

31.1 Introduction

The NV commands are used to create, update, read, and delete allocations of space in NV memory. Before an Index may be used, it must be defined (TPM2_NV_DefineSpace()).

An Index may be modified if the proper write authorization is provided or read if the proper read authorization is provided. Different controls are available for reading and writing.

An Index may have an Index-specific *authValue* and *authPolicy*. The *authValue* may be used to authorize reading if TPMA_NV_AUTHREAD is SET and writing if TPMA_NV_AUTHWRITE is SET. The *authPolicy* may be used to authorize reading if TPMA_NV_POLICYREAD is SET and writing if TPMA_NV_POLICYWRITE is SET.

For commands that have both *authHandle* and *nvIndex* parameters, *authHandle* can be an NV Index, Platform Authorization, or Owner Authorization. If *authHandle* is an NV Index, it must be the same as *nvIndex* (TPM_RC_NV_AUTHORIZATION).

TPMA_NV_PPREAD and TPMA_NV_PPWRITE indicate if reading or writing of the NV Index may be authorized by *platformAuth* or *platformPolicy*.

TPMA_NV_OWNERREAD and TPMA_NV_OWNERWRITE indicate if reading or writing of the NV Index may be authorized by *ownerAuth* or *ownerPolicy*.

If an operation on an NV index requires authorization, and the authHandle parameter is the handle of an NV Index, then the nvIndex parameter must have the same value or the TPM will return TPM_RC_NV_AUTHORIZATION.

NOTE 1 This check ensures that the authorization that was provided is associated with the NV Index being authorized.

For creating an Index, Owner Authorization may not be used if *shEnable* is CLEAR and Platform Authorization may not be used if *phEnableNV* is CLEAR.

If an Index was defined using Platform Authorization, then that Index is not accessible when *phEnableNV* is CLEAR. If an Index was defined using Owner Authorization, then that Index is not accessible when *shEnable* is CLEAR.

For read access control, any combination of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD is allowed as long as at least one is SET.

For write access control, any combination of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE is allowed as long as at least one is SET.

If an Index has been defined and not written, then any operation on the NV Index that requires read authorization will fail (TPM_RC_NV_INITIALIZED). This check may be made before or after other authorization checks but shall be performed before checking the NV Index *authValue*. An authorization failure due to the NV Index not having been written shall not be logged by the dictionary attack logic.

If TPMA_NV_CLEAR_STCLEAR is SET, then the TPMA_NV_WRITTEN will be CLEAR on each TPM2_Startup(TPM_SU_CLEAR). TPMA_NV_CLEAR_STCLEAR shall not be SET if the *nvIndexType* is TPM_NT_COUNTER.

The code in the “Detailed Actions” clause of each command is written to interface with an implementation-dependent library that allows access to NV memory. The actions assume no specific layout of the structure of the NV data.

Only one NV Index may be directly referenced in a command.

NOTE 2 This means that, if *authHandle* references an NV Index, then *nvIndex* will have the same value. However, this does not limit the number of changes that may occur as side effects. For example, any number of NV Indexes might be relocated as a result of deleting or adding a NV Index.

31.2 NV Counters

When an Index has the TPM_NT_COUNTER attribute, it behaves as a monotonic counter and may only be updated using TPM2_NV_Increment().

When an NV counter is created, the TPM shall initialize the 8-octet counter value with a number that is greater than any count value for any NV counter on the TPM since the time of TPM manufacture.

An NV counter may be defined with the TPMA_NV_ORDERLY attribute to indicate that the NV Index is expected to be modified at a high frequency and that the data is only required to persist when the TPM goes through an orderly shutdown process. The TPM may update the counter value in RAM and occasionally update the non-volatile version of the counter. An orderly shutdown is one occasion to update the non-volatile count. If the difference between the volatile and non-volatile version of the counter becomes as large as MAX_ORDERLY_COUNT, this shall be another occasion for updating the non-volatile count.

Before an NV counter can be used, the TPM shall validate that the count is not less than a previously reported value. If the TPMA_NV_ORDERLY attribute is not SET, or if the TPM experienced an orderly shutdown, then the count is assumed to be correct. If the TPMA_NV_ORDERLY attribute is SET, and the TPM shutdown was not orderly, then the TPM shall OR MAX_ORDERLY_COUNT to the contents of the non-volatile counter and set that as the current count.

NOTE 1 Because the TPM would have updated the NV Index if the difference between the count values was equal to MAX_ORDERLY_COUNT + 1, the highest value that could have been in the NV Index is MAX_ORDERLY_COUNT so it is safe to restore that value.

NOTE 2 The TPM may implement the RAM portion of the counter such that the effective value of the NV counter is the sum of both the volatile and non-volatile parts. If so, then the TPM may initialize the RAM version of the counter to MAX_ORDERLY_COUNT and no update of NV is necessary.

NOTE 3 When a new NV counter is created, the TPM may search all the counters to determine which has the highest value. In this search, the TPM would use the sum of the non-volatile and RAM portions of the counter. The RAM portion of the counter shall be properly initialized to reflect shutdown process (orderly or not) of the TPM.

31.3 TPM2_NV_DefineSpace

31.3.1 General Description

This command defines the attributes of an NV Index and causes the TPM to reserve space to hold the data associated with the NV Index. If a definition already exists at the NV Index, the TPM will return TPM_RC_NV_DEFINED.

The TPM will return TPM_RC_ATTRIBUTES if *nvIndexType* has a reserved value in *publicInfo.*

NOTE 1 It is not required that any of these three attributes be set.

The TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_WRITTEN, TPMA_NV_READLOCKED, or TPMA_NV_WRITELOCKED is SET.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS, TPM_NT_PIN_FAIL, or TPM_NT_PIN_PASS, then *publicInfo→dataSize* shall be set to eight (8) or the TPM shall return TPM_RC_SIZE.

If *nvIndexType* is TPM_NT_EXTEND, then *publicInfo→dataSize* shall match the digest size of the *publicInfo.nameAlg* or the TPM shall return TPM_RC_SIZE.

NOTE 2 TPM_RC_ATTRIBUTES could be returned by a TPM that is based on the reference code of older versions of the specification but the correct response for this error is TPM_RC_SIZE.

If the NV Index is an ordinary Index and *publicInfo→dataSize* is larger than supported by the TPM implementation then the TPM shall return TPM_RC_SIZE.

NOTE 3 The limit for the data size may vary according to the type of the index. For example, if the index has TPMA_NV_ORDERLY SET, then the maximum size of an ordinary NV Index may be less than the size of an ordinary NV Index that has TPMA_NV_ORDERLY CLEAR.

At least one of TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, or TPMA_NV_POLICYREAD shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

At least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_CLEAR_STCLEAR is SET, then *nvIndexType* shall not be TPM_NT_COUNTER or the TPM shall return TPM_RC_ATTRIBUTES.

If *platformAuth/platformPolicy* is used for authorization, then TPMA_NV_PLATFORMCREATE shall be SET in *publicInfo*. If *ownerAuth/ownerPolicy* is used for authorization, TPMA_NV_PLATFORMCREATE shall be CLEAR in *publicInfo.* If TPMA_NV_PLATFORMCREATE is not set correctly for the authorization, the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_POLICY_DELETE is SET, then the authorization shall be with Platform Authorization or the TPM shall return TPM_RC_ATTRIBUTES.

If *nvIndexType* is TPM_NT_PIN_FAIL, then TPMA_NV_NO_DA shall be SET. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 4 The intent of a PIN Fail index is that its DA protection is on a per-index basis, not based on the global DA protection. This avoids conflict over which type of dictionary attack protection is in use.

If *nvIndexType* is TPM_NT_PIN_FAIL or TPM_NT_PIN_PASS, then at least one of TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, or TPMA_NV_POLICYWRITE shall be SET or the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_AUTHWRITE shall be CLEAR. Otherwise, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 5 If TPMA_NV_AUTHWRITE was SET for a PIN Pass index, a user knowing the authorization value could decrease pinCount or increase pinLimit, defeating the purpose of a PIN Pass index. The requirement is also enforced for a PIN Fail index for consistency.

 Copyright © TCG 2006-2020

If the implementation does not support TPM2_NV_Increment(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_COUNTER.

If the implementation does not support TPM2_NV_SetBits(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_BITS.

If the implementation does not support TPM2_NV_Extend(), the TPM shall return TPM_RC_ATTRIBUTES if *nvIndexType* is TPM_NT_EXTEND.

If the implementation does not support TPM2_NV_UndefineSpaceSpecial(), the TPM shall return TPM_RC_ATTRIBUTES if TPMA_NV_POLICY_DELETE is SET.

After the successful completion of this command, the NV Index exists but TPMA_NV_WRITTEN will be CLEAR. Any access of the NV data will return TPM_RC_NV_UNINITIALIZED.

In some implementations, an NV Index with the TPM_NT_COUNTER attribute may require special TPM resources that provide higher endurance than regular NV. For those implementations, if this command fails because of lack of resources, the TPM will return TPM_RC_NV_SPACE.

The value of *auth* is saved in the created structure. The size of *auth* is limited to be no larger than the size of the digest produced by the NV Index's *nameAlg* (TPM_RC_SIZE).

31.4 TPM2_NV_UndefineSpace

31.4.1 General Description

This command removes an Index from the TPM.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE attribute SET, the TPM shall return TPM_RC_NV_AUTHORIZATION unless Platform Authorization is provided.

If *nvIndex* references an Index that has its TPMA_NV_POLICY_DELETE attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR may be deleted with Platform Authorization as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

31.5 TPM2_NV_UndefineSpaceSpecial

31.5.1 General Description

This command allows removal of a platform-created NV Index that has TPMA_NV_POLICY_DELETE SET.

This command requires that the policy of the NV Index be satisfied before the NV Index may be deleted. Because administrative role is required, the policy must contain a command that sets the policy command code to TPM_CC_NV_UndefineSpaceSpecial. This indicates that the policy that is being used is a policy that is for this command, and not a policy that would approve another use. That is, authority to use an entity does not grant authority to undefine the entity.

Since the index is deleted, the Empty Buffer is used as the authValue when generating the response HMAC.

If *nvIndex* is not defined, the TPM shall return TPM_RC_HANDLE.

If *nvIndex* references an Index that has its TPMA_NV_PLATFORMCREATE or TPMA_NV_POLICY_DELETE attribute CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE An Index with TPMA_NV_PLATFORMCREATE CLEAR may be deleted with TPM2_UndefineSpace()as long as shEnable is SET. If shEnable is CLEAR, indexes created using Owner Authorization are not accessible even for deletion by the platform.

31.7 TPM2_NV_Write

31.7.1 General Description

This command writes a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPWRITE; TPMA_NV_OWNERWRITE; TPMA_NV_AUTHWRITE; and, if TPMA_NV_POLICY_WRITE is SET, the *authPolicy* of the NV Index.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 1 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

If *nvIndexType* is TPM_NT_COUNTER, TPM_NT_BITS or TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

If the TPMA_NV_WRITEALL attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_RANGE if the size of the *data* parameter of the command is not the same as the *data* field of the NV Index.

If all checks succeed, the TPM will merge the *data.size* octets of *data.buffer* value into the *nvIndex→data* starting at *nvIndex→data[offset].* If the NV memory is implemented with a technology that has endurance limitations, the TPM shall check that the merged data is different from the current contents of the NV Index and only perform a write to NV memory if they differ.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 2 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined or the NV Index is cleared.

31.8 TPM2_NV_Increment

31.8.1 General Description

This command is used to increment the value in an NV Index that has the TPM_NT_COUNTER attribute. The data value of the NV Index is incremented by one.

NOTE 1 The NV Index counter is an unsigned value.

If *nvIndexType* is not TPM_NT_COUNTER in the indicated NV Index, the TPM shall return TPM_RC_ATTRIBUTES.

If TPMA_NV_WRITELOCKED is SET, the TPM shall return TPM_RC_NV_LOCKED.

If TPMA_NV_WRITTEN is CLEAR, it will be SET.

If TPMA_NV_ORDERLY is SET, and the difference between the volatile and non-volatile versions of this field is greater than MAX_ORDERLY_COUNT, then the non-volatile version of the counter is updated.

NOTE 2 If a TPM implements TPMA_NV_ORDERLY and an Index is defined with TPMA_NV_ORDERLY and TPM_NT_COUNTER both SET, then in the Event of a non-orderly shutdown, the non-volatile value for the counter Index will be advanced by MAX_ORDERLY_COUNT at the next TPM2_Startup().

NOTE 3 An allowed implementation would keep a counter value in NV and a resettable counter in RAM. The reported value of the NV Index would be the sum of the two values. When the RAM count increments past the maximum allowed value (MAX_ORDERLY_COUNT), the non-volatile version of the count is updated with the sum of the values and the RAM count is reset to zero.

```

31.9 TPM2_NV_Extend

31.9.1 General Description

This command extends a value to an area in NV memory that was previously defined by TPM2_NV_DefineSpace.

If *nvIndexType* is not TPM_NT_EXTEND, then the TPM shall return TPM_RC_ATTRIBUTES.

Proper write authorizations are required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and the *authPolicy* of the NV Index.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE 1 Once SET, TPMA_NV_WRITTEN remains SET until the NV Index is undefined, unless the TPMA_NV_CLEAR_STCLEAR attribute is SET and a TPM Reset or TPM Restart occurs.

If the TPMA_NV_WRITELOCKED attribute of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

NOTE 2 If authorization sessions are present, they are checked before checks to see if writes to the NV Index are locked.

The *data.buffer* parameter may be larger than the defined size of the NV Index.

The Index will be updated by:

$$nvIndex{\rightarrow}data_{new} \coloneqq \mathbf{H}_{nameAkg}(nvIndex{\rightarrow}data_{old} \mid\mid data.buffer) \qquad (41)$$

where

$nvIndex{\rightarrow}data_{new}$	the value of the data field in the NV Index after the command returns
$\mathbf{H}_{nameAkg}()$	the hash algorithm indicated in *nvIndex→nameAlg*
$nvIndex{\rightarrow}data_{old}$	the value of the data field in the NV Index before the command is called
$data.buffer$	the data buffer of the command parameter

NOTE 3 If TPMA_NV_WRITTEN is CLEAR, then $nvIndex{\rightarrow}data_{old}$ is a Zero Digest.

```

31.10 TPM2_NV_SetBits

31.10.1 General Description

This command is used to SET bits in an NV Index that was created as a bit field. Any number of bits from 0 to 64 may be SET. The contents of *bits* are ORed with the current contents of the NV Index.

If TPMA_NV_WRITTEN is not SET, then, for the purposes of this command, the NV Index is considered to contain all zero bits and *data* is ORed with that value.

If TPM_NT_BITS is not SET, then the TPM shall return TPM_RC_ATTRIBUTES.

After successful completion of this command, TPMA_NV_WRITTEN for the NV Index will be SET.

NOTE TPMA_NV_WRITTEN will be SET even if no bits were SET.

31.11 TPM2_NV_WriteLock

31.11.1 General Description

If the TPMA_NV_WRITEDEFINE or TPMA_NV_WRITE_STCLEAR attributes of an NV location are SET, then this command may be used to inhibit further writes of the NV Index.

Proper write authorization is required for this command as determined by TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE, TPMA_NV_AUTHWRITE, and the *authPolicy* of the NV Index.

It is not an error if TPMA_NV_WRITELOCKED for the NV Index is already SET.

If neither TPMA_NV_WRITEDEFINE nor TPMA_NV_WRITE_STCLEAR of the NV Index is SET, then the TPM shall return TPM_RC_ATTRIBUTES.

If the command is properly authorized and TPMA_NV_WRITE_STCLEAR or TPMA_NV_WRITEDEFINE is SET, then the TPM shall SET TPMA_NV_WRITELOCKED for the NV Index. TPMA_NV_WRITELOCKED will be clear on the next TPM2_Startup(TPM_SU_CLEAR) if either TPMA_NV_WRITEDEFINE is CLEAR or TPMA_NV_WRITTEN is CLEAR.

31.12 TPM2_NV_GlobalWriteLock

31.12.1 General Description

The command will SET TPMA_NV_WRITELOCKED for all indexes that have their TPMA_NV_GLOBALLOCK attribute SET.

If an Index has both TPMA_NV_GLOBALLOCK and TPMA_NV_WRITEDEFINE SET, then this command will permanently lock the NV Index for writing unless TPMA_NV_WRITTEN is CLEAR.

NOTE If an Index is defined with TPMA_NV_GLOBALLOCK SET, then the global lock does not apply until the next time this command is executed.

This command requires either platformAuth/platformPolicy or ownerAuth/ownerPolicy.

31.13 TPM2_NV_Read

31.13.1 General Description

This command reads a value from an area in NV memory previously defined by TPM2_NV_DefineSpace().

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and the *authPolicy* of the NV Index.

If TPMA_NV_READLOCKED of the NV Index is SET, then the TPM shall return TPM_RC_NV_LOCKED.

If *offset* and the *size* field of *data* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

NOTE 1 If authorization sessions are present, they are checked before the read-lock status of the NV Index is checked.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

The *data* parameter in the response may be encrypted using parameter encryption.

31.14 TPM2_NV_ReadLock

31.14.1 General Description

If TPMA_NV_READ_STCLEAR is SET in an Index, then this command may be used to prevent further reads of the NV Index until the next TPM2_Startup (TPM_SU_CLEAR).

Proper authorizations are required for this command as determined by TPMA_NV_PPREAD, TPMA_NV_OWNERREAD, TPMA_NV_AUTHREAD, and the *authPolicy* of the NV Index.

NOTE Only an entity that may read an Index is allowed to lock the NV Index for read.

If the command is properly authorized and TPMA_NV_READ_STCLEAR of the NV Index is SET, then the TPM shall SET TPMA_NV_READLOCKED for the NV Index. If TPMA_NV_READ_STCLEAR of the NV Index is CLEAR, then the TPM shall return TPM_RC_ATTRIBUTES. TPMA_NV_READLOCKED will be CLEAR by the next TPM2_Startup(TPM_SU_CLEAR).

It is not an error to use this command for an Index that is already locked for reading.

An Index that had not been written may be locked for reading.

31.15 TPM2_NV_ChangeAuth

31.15.1 General Description

This command allows the authorization secret for an NV Index to be changed.

If successful, the authorization secret (*authValue*) of the NV Index associated with *nvIndex* is changed.

This command requires that a policy session be used for authorization of *nvIndex* so that the ADMIN role may be asserted and that *commandCode* in the policy session context shall be TPM_CC_NV_ChangeAuth. That is, the policy must contain a specific authorization for changing the authorization value of the referenced entity.

NOTE The reason for this restriction is to ensure that the administrative actions on *nvIndex* require explicit approval while other commands may use policy that is not command-dependent.

The size of the *newAuth* value may be no larger than the size of the digest produced by the *nameAlg* of the NV Index.

Since the NV Index authorization is changed before the response HMAC is calculated, the newAuth value is used when generating the response HMAC key if required. See TPM 2.0 Part 4 ComputeResponseHMAC().

31.16 TPM2_NV_Certify

31.16.1 General Description

The purpose of this command is to certify the contents of an NV Index or portion of an NV Index.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

If the NV Index has been defined but the TPMA_NV_WRITTEN attribute is CLEAR, then this command shall return TPM_RC_NV_UNINITIALIZED even if *size* is zero.

If proper authorization for reading the NV Index is provided, the portion of the NV Index selected by *size* and *offset* are included in an attestation block and signed using the key indicated by *signHandle*. The attestation includes *size* and *offset* so that the range of the data can be determined. It also includes the NV index Name.

For an NV Index with the TPM_NT_COUNTER or TPM_NT_BITS attribute SET, the TPM may ignore the *offset* parameter and use an offset of 0. Therefore, it is recommended that the caller set the *offset* parameter to 0 for interoperability.

If *offset* and *size* add to a value that is greater than the *dataSize* field of the NV Index referenced by *nvIndex*, the TPM shall return an error (TPM_RC_NV_RANGE). The implementation may return an error (TPM_RC_VALUE) if it performs an additional check and determines that *offset* is greater than the *dataSize* field of the NV Index, or if *size* is greater than MAX_NV_BUFFER_SIZE.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

If *size* and *offset* are both zero (0), then *certifyInfo* in the response will contain a TPMS_NV_DIGEST_CERTIFY_INFO, otherwise, it will contain a TPMS_NV_CERTIFY_INFO. The digest in the TPMS_NV_DIGEST_CERTIFY_INFO is created using the digest of the selected signing scheme.

NOTE 3 TPMS_NV_DIGEST_CERTIFY_INFO was added in revision 01.53. It permits TPM2_NV_Certify() to certify NV Index contents that are larger than MAX_NV_BUFFER_SIZE.

32 Attached Components

32.1 Introduction

This section contains commands that allow interaction with an Attached Component (AC).

NOTE The Attached Component feature was added in revision 01.40.

 Copyright © TCG 2006-2020

32.2 TPM2_AC_GetCapability

32.2.1 General Description

The purpose of this command is to obtain information about an Attached Component referenced by an AC handle.

The returned list contains 0 or more values starting at the first tagged value that is equal to or greater than *capability*.

The list returned in *capabilitiesData* contains tagged values that indicate the type of the value.

The TPM will return the lesser of a) the available values, b) the number requested in *count,* or c) the number that will fit within the available response buffer. If additional values with higher *capability* numbers are available, *moreData* will be YES.

NOTE TPM2_AC_GetCapability() was added in revision 01.40.

32.3 TPM2_AC_Send

32.3.1 General Description

The purpose of this command is to send (copy) a loaded object from the TPM to an Attached Component.

The Object referenced by *sendObject* is required to have *fixedTpm, fixedParent,* and *encryptedDuplication* attributes CLEAR (TPM_RC_ATTRIBUTES). Authorization for *sendObject* is required to be a policy session. The *policySession→commandCode* of the policy session context is required to be TPM_CC_AC_Send (TPM_RC_POLICY_FAIL) to demonstrate that the policy is specific for this command.

Authorization to send to the *ac* is provided by the session associated with *authHandle*.

If an NV Alias is not defined for *ac,* then *authHandle* is required to be either TPM_RH_OWNER or TPM_RH_PLATFORM (TPM_RC_HANDLE).

If an NV Alias is defined for *ac*, then the authorization for *authHandle* is required to be compatible with the write authorization attributes (TPMA_NV_PPWRITE, TPMA_NV_OWNERWRITE TPMA_NV_AUTHWRITE, and TPMA_NV_POLICYWRITE) in the NV Alias (TPM_RC_NV_AUTHORIZATION).

NOTE 1 If authorization for *authHandle* is the handle of an NV Index, then it is required to be the NV Alias value for *ac* (TPM_RC_NV_AUTHORIZATION).

If authorization succeeds, the TPM will attempt to send *acDataIn* and relevant portions of *sendObject* to the AC referenced by *ac*.

The TPM will return TPM_RC_SUCCESS if it succeeds in performing all the required authorizations and validations. If problems occur in the process of sending the object from the TPM to the AC, the response code will be TPM_RC_SUCCESS with the AC-dependent error reported in acDataOut.

NOTE 2 TPM2_AC_Send() was added in revision 01.40.

32.4 TPM2_Policy_AC_SendSelect

32.4.1 General Description

This command allows qualification of the sending (copying) of an Object to an Attached Component (AC). Qualification includes selection of the receiving AC and the method of authentication for the AC, and, in certain circumstances, the Object to be sent may be specified.

If this command is not used in conjunction with TPM2_PolicyAuthorize(), then only the *authHandleName* and *acName* are selected and *includeObject* should be CLEAR.

NOTE 1 In the absence of TPM2_PolicyAuthorize(), a policy session cannot create a *policyDigest* that simultaneously equals the *authPolicy* in an Object and names that Object. This is because the *authPolicy* recorded in an Object is unable to include the Name of the Object as the Name of an Object depends on the Object's *authPolicy*.

NOTE 2 An object's *authPolicy* can incorporate the use of TPM2_PolicyAuthorize(). If the authorizing entity for the TPM2_PolicyAuthorize() command specifies only the *ac* and the *authHandle*, then the resultant *policyDigest* may be applied to the sending of any number of Objects. If the authorizing entity for the TPM2_PolicyAuthorize() specifies also the Name of the Object to be sent, then the resultant *policyDigest* applies only to that specific Object.

If either policySession→cpHash or policySession→nameHash has been previously set, the TPM shall return TPM_RC_CPHASH. Otherwise, policySession→nameHash will be set to:

$$nameHash \coloneqq \mathbf{H}_{policyAlg}(objectName \mathbin{||} authHandleName \mathbin{||} acName) \quad (42)$$

NOTE 3 A policy cannot specify both *cpHash* and *nameHash* because *policySession→nameHash* and *policySession→cpHash* may share the same memory space.

If the command succeeds, *policySession→policyDigest* will be updated according to the setting of the input parameter *includeObject*. If *includeObject* is SET, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_Policy_AC_SendSelect} \mathbin{||} objectName \mathbin{||} authHandleName \mathbin{||} acName \mathbin{||} includeObject) \quad (43)$$

but if includeObject is CLEAR, *policySession→policyDigest* is updated by:

$$policyDigest_{new} \coloneqq \mathbf{H}_{policyAlg}(policyDigest_{old} \mathbin{||} \text{TPM_CC_Policy_AC_SendSelect} \mathbin{||} authHandleName \mathbin{||} acName \mathbin{||} includeObject) \quad (44)$$

NOTE 4 *policySession→nameHash* receives the digest of all Names so that the check performed in TPM2_AC_Send() may be the same regardless of which Names are included in *policySession→policyDigest*. This means that, when TPM2_Policy_AC_SendSelect() is executed, it is only valid for a specific triple of *objectName*, *authHandleName*, and *acName*.

If the command succeeds, *policySession→commandCode* is set to TPM_CC_AC_Send.

NOTE 5 The normal use of TPM2_Policy_AC_SendSelect() is before a TPM2_PolicyAuthorize(). An authorized entity would approve a *policyDigest* that allows sending to a specific Attached Component. The authorizing entity may want to limit the authorization so that the approval allows only a specific Object to be sent to the Attached Component. In that case, the authorizing entity would approve the *policyDigest* of *equation* (44).

NOTE 6 TPM2_Policy_AC_SendSelect() was added in revision 01.40.

33 Authenticated Countdown Timer

33.1 Introduction

This section contains commands that allow interaction with an Authenticated Countdown Timer (ACT).

NOTE The Authenticated Countdown Timer was added in revision 01.56.

33.2 TPM2_ACT_SetTimeout

33.2.1 General Description

This command is used to set the time remaining before an Authenticated Countdown Timer (ACT) expires.

This command sets TPMS_ACT_DATA.*timeout* (ACT Timeout) to *startTimeout*. The *startTimeout* value is an integer number of seconds and may be zero. The *startTimeout* parameter may be greater, equal, or less than the current value of ACT Timeout.

When ACT Timeout is non-zero, it will count down, once per second until it reaches zero, at which time the *signaled* attribute of the TPMA_ACT associated with *actHandle* is SET.

When ACT Timeout is zero and the *signaled* attribute is SET, writing a *startTimeout* of FF FF FF FF_{16} will clear *signaled* and stop the counting.

There are four states for ACT Timeout and *startTimeout*. The *signaled* attribute will be set as follows:

1) If ACT Timeout is zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.

2) If ACT Timeout is non-zero and *startTimeout* is non-zero, then *signaled* will be CLEAR.

3) If ACT Timeout is zero and *startTimeout* is zero, then *signaled* will be unchanged.

4) If ACT Timeout is non-zero and *startTimeout* is zero, then *signaled* will be SET.

NOTE 1 The ACT signals on a transition from non-zero to zero. The transition can occur either due to TPM2_ACT_SetTimeout() or a decrement. The effect of *signaled* is platform dependent.

NOTE 2 It may take up to one second until ACT Timeout will be set and *signaled* will be CLEAR or SET by TPM2_ACT_SetTimeout() or TPM2_Startup(STATE). This allows the counting and signaling to take place synchronously with the hardware clock tick.

NOTE 3 TPM2_ACT_SetTimeout() was added in revision 01.56.

34 Vendor Specific

34.1 Introduction

This section contains commands that are vendor specific but made public in order to prevent proliferation.

This specification does define TPM2_Vendor_TCG_Test() in order to have at least one command that can be used to ensure the proper operation of the command dispatch code when processing a vendor-specific command.

34.2 TPM2_Vendor_TCG_Test

34.2.1 General Description

This is a placeholder to allow testing of the dispatch code.

34.2.2 Command and Response

Table 248 — TPM2_Vendor_TCG_Test Command

Type	Name	Description
TPMI_ST_COMMAND_TAG	tag	TPM_ST_SESSIONS if an audit session is present; otherwise, TPM_ST_NO_SESSIONS
UINT32	commandSize	
TPM_CC	commandCode	TPM_CC_Vendor_TCG_Test
TPM2B_DATA	inputData	dummy data

Table 249 — TPM2_Vendor_TCG_Test Response

Type	Name	Description
TPM_ST	tag	see clause 6
UINT32	responseSize	
TPM_RC	responseCode	TPM_RC_SUCCESS
TPM2B_DATA	outputData	dummy data

 Copyright © TCG 2006-2020

34.2.3 Detailed Actions

```
1  #include "Tpm.h"
2  #if CC_Vendor_TCG_Test      // Conditional expansion of this file
3  #include "Vendor_TCG_Test_fp.h"
4  TPM_RC
5  TPM2_Vendor_TCG_Test(
6      Vendor_TCG_Test_In        *in,             // IN: input parameter list
7      Vendor_TCG_Test_Out       *out             // OUT: output parameter list
8      )
9  {
10     out->outputData = in->inputData;
11     return TPM_RC_SUCCESS;
12 }
13 #endif // CC_Vendor_TCG_Test
```

Trusted Platform Module Library
Part 3: Commands

1 Scope

This TPM 2.0 Part 3 of the *Trusted Platform Module Library* specification contains the definitions of the TPM commands. These commands make use of the constants, flags, structures, and union definitions defined in TPM 2.0 Part 2.

The detailed description of the operation of the commands is written in the C language with extensive comments. The behavior of the C code in this TPM 2.0 Part 3 is normative but does not fully describe the behavior of a TPM. The combination of this TPM 2.0 Part 3 and TPM 2.0 Part 4 is sufficient to fully describe the required behavior of a TPM.

The code in parts 3 and 4 is written to define the behavior of a compliant TPM. In some cases (e.g., firmware update), it is not possible to provide a compliant implementation. In those cases, any implementation provided by the vendor that meets the general description of the function provided in TPM 2.0 Part 3 would be compliant.

The code in parts 3 and 4 is not written to meet any particular level of conformance nor does this specification require that a TPM meet any particular level of conformance.

2 Terms and Definitions

For the purposes of this document, the terms and definitions given in TPM 2.0 Part 1 apply.

3 Symbols and abbreviated terms

For the purposes of this document, the symbols and abbreviated terms given in TPM 2.0 Part 1 apply.

Copyright © TCG 2006-2020

4 Notation

4.1 Introduction

For the purposes of this document, the notation given in TPM 2.0 Part 1 applies.

Command and response tables use various decorations to indicate the fields of the command and the allowed types. These decorations are described in this clause.

4.2 Table Decorations

The symbols and terms in the Notation column of Table 1 are used in the tables for the command schematics. These values indicate various qualifiers for the parameters or descriptions with which they are associated.

Table 1 — Command Modifiers and Decoration

Notation	Meaning
+	A Type decoration – When appended to a value in the Type column of a command, this symbol indicates that the parameter is allowed to use the "null" value of the data type (see in TPM 2.0 Part 2, *Conditional Types*). The null value is usually TPM_RH_NULL for a handle or TPM_ALG_NULL for an algorithm selector. NOTE This decoration is not appended to response parameters.
@	A Name decoration – When this symbol precedes a handle parameter in the "Name" column, it indicates that an authorization session is required for use of the entity associated with the handle. If a handle does not have this symbol, then an authorization session is not allowed.
+PP	A Description modifier – This modifier may follow TPM_RH_PLATFORM in the "Description" column to indicate that Physical Presence is required when *platformAuth*/*platformPolicy* is provided.
+{PP}	A Description modifier – This modifier may follow TPM_RH_PLATFORM to indicate that Physical Presence may be required when *platformAuth*/*platformPolicy* is provided. The commands with this notation may be in the *setList* or *clearList* of TPM2_PP_Commands().
{NV}	A Description modifier – This modifier may follow the *commandCode* in the "Description" column to indicate that the command may result in an update of NV memory and be subject to rate throttling by the TPM. If the command code does not have this notation, then a write to NV memory does not occur as part of the command actions. NOTE Any command that uses authorization may cause a write to NV if there is an authorization failure. A TPM may use the occasion of command execution to update the NV copy of clock.
{F}	A Description modifier – This modifier indicates that the "flushed" attribute will be SET in the TPMA_CC for the command. The modifier may follow the *commandCode* in the "Description" column to indicate that any transient handle context used by the command will be flushed from the TPM when the command completes. This may be combined with the {NV} modifier but not with the {E} modifier. EXAMPLE 1 {NV F} EXAMPLE 2 TPM2_SequenceComplete() will flush the context associated with the *sequenceHandle*.
{E}	A Description modifier – This modifier indicates that the "extensive" attribute will be SET in the TPMA_CC for the command. This modifier may follow the *commandCode* in the "Description" column to indicate that the command may flush many objects and re-enumeration of the loaded context likely will be required. This may be combined with the {NV} modifier but not with the {F} modifier. EXAMPLE 1 {NV E} EXAMPLE 2 TPM2_Clear() will flush all contexts associated with the Storage hierarchy and the Endorsement hierarchy.

 Copyright © TCG 2006-2020

Notation	Meaning
Auth Index:	A Description modifier – When a handle has a “@” decoration, the “Description” column will contain an “Auth Index:” entry for the handle. This entry indicates the number of the authorization session. The authorization sessions associated with handles will occur in the session area in the order of the handles with the “@” modifier. Sessions used only for encryption/decryption or only for audit will follow the handles used for authorization.
Auth Role:	A Description modifier – This will be in the “Description” column of a handle with the “@” decoration. It may have a value of USER, ADMIN or DUP. If the handle has the Auth Role of USER and the handle is an Object, the type of authorization is determined by the setting of *userWithAuth* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *userWithAuth* is SET. If the handle references an NV Index, then the allowed authorizations are determined by the settings of the attributes of the NV Index as described in TPM 2.0 Part 2, "TPMA_NV (NV Index Attributes)." If the Auth Role is ADMIN and the handle is an Object, the type of authorization is determined by the setting of *adminWithPolicy* in the Object's attributes. If the handle is TPM_RH_OWNER, TPM_RH_ENDORSEMENT, or TPM_RH_PLATFORM, operation is as if *adminWithPolicy* is SET. If the handle is an NV index, operation is as if *adminWithPolicy* is SET (see 5.6 e)2)). If the DUP role is selected, authorization may only be with a policy session (DUP role only applies to Objects). When either ADMIN or DUP role is selected, a policy command that selects the command being authorized is required to be part of the policy. EXAMPLE TPM2_Certify requires the ADMIN role for the first handle (*objectHandle*). The policy authorization for objectHandle is required to contain TPM2_PolicyCommandCode(*commandCode* == TPM_CC_Certify). This sets the state of the policy so that it can be used for ADMIN role authorization in TPM2_Certify().

4.3 Handle and Parameter Demarcation

The demarcations between the header, handle, and parameter parts are indicated by:

Table 2 — Separators

Separator	Meaning
(dashed line)	the values immediately following are in the handle area
(double line)	the values immediately following are in the parameter area

4.4 AuthorizationSize and ParameterSize

Authorization sessions are not shown in the command or response schematics. When the tag of a command or response is TPM_ST_SESSIONS, then a 32-bit value will be present in the command/response buffer to indicate the size of the authorization field or the parameter field. This value shall immediately follow the handle area (which may contain no handles). For a command, this value (*authorizationSize*) indicates the size of the Authorization Area and shall have a value of 9 or more. For a response, this value (*parameterSize*) indicates the size of the parameter area and may have a value of zero.

If the *authorizationSize* field is present in the command, *parameterSize* will be present in the response, but only if the *responseCode* is TPM_RC_SUCCESS.

When authorization is required to use the TPM entity associated with a handle, then at least one session will be present. To indicate this, the command *tag* Description field contains TPM_ST_SESSIONS. Addional sessions for audit, encrypt, and decrypt may be present.

 Copyright © TCG 2006-2020

When the command *tag* Description field contains TPM_ST_NO_SESSIONS, then no sessions are allowed and the *authorizationSize* field is not present.

When a command allows use of sessions when not required, the command *tag* Description field will indicate the types of sessions that may be used with the command.

4.5 Return Code Alias

For the RC_FMT1 return codes that may add a parameter, handle, or session number, the prefix TPM_RCS_ is an alias for TPM_RC_.

TPM_RC_n is added, where n is the parameter, handle, or session number. In addition, TPM_RC_H is added for handle, TPM_RC_P for parameter, and TPM_RC_S for session errors.

NOTE TPM_RCS_ is a programming convention. Programmers should only add numbers to TPM_RCS_ return codes, never TPM_RC_ return codes. Only return codes that can have a number added have the TPM_RCS_ alias defined. Attempting to use a TPM_RCS_ return code that does not have the TPM_RCS_ alias will cause a compiler error.

EXAMPLE 1 Since TPM_RC_VALUE can have a number added, TPM_RCS_VALUE is defined. A program can use the construct "TPM_RCS_VALUE + number". Since TPM_RC_SIGNATURE cannot have a number added, TPM_RCS_SIGNATURE is not defined. A program using the construct "TPM_RCS_SIGNATURE + number" will not compile, alerting the programmer that the construct is incorrect.

By convention, the number to be added is of the form RC_CommandName_ParameterName where CommmandName is the name of the command with the TPM2_ prefix removed. The parameter name alone is insufficient because the same parameter name could be in a different position in different commands.

EXAMPLE 2 TPM2_HMAC_Start with parameters that result in TPM_ALG_NULL as the hash algorithm will returns TPM_RC_VALUE plus the parameter number. Since *hashAlg* is the second parameter, This code results:

```
#define RC_HMAC_Start_hashAlg          (TPM_RC_P + TPM_RC_2)

return TPM_RCS_VALUE + RC_HMAC_Start_hashAlg;
```

5 Command Processing

5.1 Introduction

This clause defines the command validations that are required of any implementation and the response code returned if the indicated check fails. Unless stated otherwise, the order of the checks is not normative and different TPM may give different responses when a command has multiple errors.

In the description below, some statements that describe a check may be followed by a response code in parentheses. This is the normative response code should the indicated check fail. A normative response code may also be included in the statement.

5.2 Command Header Validation

Before a TPM may begin the actions associated with a command, a set of command format and consistency checks shall be performed. These checks are listed below and should be performed in the indicated order.

a) The TPM shall successfully unmarshal a TPMI_ST_COMMAND_TAG and verify that it is either TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS (TPM_RC_BAD_TAG).

 Copyright © TCG 2006-2020

b) The TPM shall successfully unmarshal a UINT32 as the *commandSize*. If the TPM has an interface buffer that is loaded by some hardware process, the number of octets in the input buffer for the command reported by the hardware process shall exactly match the value in *commandSize* (TPM_RC_COMMAND_SIZE).

NOTE A TPM may have direct access to system memory and unmarshal directly from that memory.

c) The TPM shall successfully unmarshal a TPM_CC and verify that the command is implemented (TPM_RC_COMMAND_CODE).

5.3 Mode Checks

The following mode checks shall be performed in the order listed:

a) If the TPM is in Failure mode, then the *commandCode* is TPM_CC_GetTestResult or TPM_CC_GetCapability (TPM_RC_FAILURE) and the command *tag* is TPM_ST_NO_SESSIONS (TPM_RC_FAILURE).

NOTE 1 In Failure mode, the TPM has no cryptographic capability and processing of sessions is not supported.

b) The TPM is in Field Upgrade mode (FUM), the *commandCode* is TPM_CC_FieldUpgradeData (TPM_RC_UPGRADE).

c) If the TPM has not been initialized (TPM2_Startup()), then the *commandCode* is TPM_CC_Startup (TPM_RC_INITIALIZE).

NOTE 2 The TPM may enter Failure mode during _TPM_Init processing, before TPM2_Startup(). Since the platform firmware cannot know that the TPM is in Failure mode without accessing it, and since the first command is required to be TPM2_Startup(), the expected sequence will be that platform firmware (the CRTM) will issue TPM2_Startup() and receive TPM_RC_FAILURE indicating that the TPM is in Failure mode.

There may be failures where a TPM cannot record that it received TPM2_Startup(). In those cases, a TPM in failure mode may process TPM2_GetTestResult(), TPM2_GetCapability(), or the field upgrade commands. As a side effect, that TPM may process TPM2_GetTestResult(), TPM2_GetCapability() or the field upgrade commands before TPM2_Startup().

This is a corner case exception to the rule that TPM2_Startup() must be the first command.

The mode checks may be performed before or after the command header validation.

5.4 Handle Area Validation

After successfully unmarshaling and validating the command header, the TPM shall perform the following checks on the handles and sessions. These checks may be performed in any order.

NOTE 1 A TPM is required to perform the handle area validation before the authorization checks because an authorization cannot be performed unless the authorization values and attributes for the referenced entity are known by the TPM. For them to be known, the referenced entity must be in the TPM and accessible.

a) The TPM shall successfully unmarshal the number of handles required by the command and validate that the value of the handle is consistent with the command syntax. If not, the TPM shall return TPM_RC_VALUE.

NOTE 2 The TPM may unmarshal a handle and validate that it references an entity on the TPM before unmarshaling a subsequent handle.

NOTE 3 If the submitted command contains fewer handles than required by the syntax of the command, the TPM may continue to read into the next area and attempt to interpret the data as a handle.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

b) For all handles in the handle area of the command, the TPM will validate that the referenced entity is present in the TPM.

1) If the handle references a transient object, the handle shall reference a loaded object (TPM_RC_REFERENCE_H0 + N where N is the number of the handle in the command).

NOTE 4 If the hierarchy for a transient object is disabled, then the transient objects will be flushed so this check will fail.

2) If the handle references a persistent object, then

i) the hierarchy associated with the object (platform or storage, based on the handle value) is enabled (TPM_RC_HANDLE);

ii) the handle shall reference a persistent object that is currently in TPM non-volatile memory (TPM_RC_HANDLE);

iii) if the handle references a persistent object that is associated with the endorsement hierarchy, that the endorsement hierarchy is not disabled (TPM_RC_HANDLE); and

NOTE 5 The reference implementation keeps an internal attribute, passed down from a primary key to its descendents, indicating the object's hierarchy.

iv) if the TPM implementation moves a persistent object to RAM for command processing then sufficient RAM space is available (TPM_RC_OBJECT_MEMORY).

3) If the handle references an NV Index, then

i) an Index exists that corresponds to the handle (TPM_RC_HANDLE); and

ii) the hierarchy associated with the existing NV Index is not disabled (TPM_RC_HANDLE).

iii) If the command requires write access to the index data then TPMA_NV_WRITELOCKED is not SET (TPM_RC_NV_LOCKED)

iv) If the command requires read access to the index data then TPMA_NV_READLOCKED is not SET (TPM_RC_NV_LOCKED)

4) If the handle references a session, then the session context shall be present in TPM memory (TPM_RC_REFERENCE_H0 + N).

5) If the handle references a primary seed for a hierarchy (TPM_RH_ENDORSEMENT, TPM_RH_OWNER, or TPM_RH_PLATFORM) then the enable for the hierarchy is SET (TPM_RC_HIERARCHY).

6) If the handle references a PCR, then the value is within the range of PCR supported by the TPM (TPM_RC_VALUE)

NOTE 6 In the reference implementation, this TPM_RC_VALUE is returned by the unmarshaling code for a TPMI_DH_PCR.

5.5 Session Area Validation

a) If the tag is TPM_ST_SESSIONS and the command requires TPM_ST_NO_SESSIONS, the TPM will return TPM_RC_AUTH_CONTEXT.

b) If the tag is TPM_ST_NO_SESSIONS and the command requires TPM_ST_SESSIONS, the TPM will return TPM_RC_AUTH_MISSING.

c) If the tag is TPM_ST_SESSIONS, the TPM will attempt to unmarshal an *authorizationSize* and return TPM_RC_AUTHSIZE if the value is not within an acceptable range.

1) The minimum value is (sizeof(TPM_HANDLE) + sizeof(UINT16) + sizeof(TPMA_SESSION) + sizeof(UINT16)).

 Copyright © TCG 2006-2020

2) The maximum value of authorizationSize is equal to commandSize – (sizeof(TPM_ST) + sizeof(UINT32) + sizeof(TPM_CC) + (N * sizeof(TPM_HANDLE)) + sizeof(UINT32)) where N is the number of handles associated with the *commandCode* and may be zero.

NOTE 1 (sizeof(TPM_ST) + sizeof(UINT32) + sizeof(TPM_CC)) is the size of a command header. The last UINT32 contains the authorizationSize octets, which are not counted as being in the authorization session area.

d) The TPM will unmarshal the authorization sessions and perform the following validations:

1) If the session handle is not a handle for an HMAC session, a handle for a policy session, or, TPM_RS_PW then the TPM shall return TPM_RC_HANDLE.

2) If the session is not loaded, the TPM will return the warning TPM_RC_REFERENCE_S0 + N where N is the number of the session. The first session is session zero, N = 0.

NOTE 2 If the HMAC and policy session contexts use the same memory, the type of the context must match the type of the handle.

3) If the maximum allowed number of sessions have been unmarshaled and fewer octets than indicated in *authorizationSize* were unmarshaled (that is, *authorizationSize* is too large), the TPM shall return TPM_RC_AUTHSIZE.

4) The consistency of the authorization session attributes is checked.

i) Only one session is allowed for:

(a) session auditing (TPM_RC_ATTRIBUTES) – this session may be used for encrypt or decrypt but may not be a session that is also used for authorization;

(b) decrypting a command parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session, or a session may be added for the single purpose of decrypting a command parameter, as long as the total number of sessions does not exceed three; and

(c) encrypting a response parameter (TPM_RC_ATTRIBUTES) – this may be any of the authorization sessions, or the audit session if present, ora session may be added for the single purpose of encrypting a response parameter, as long as the total number of sessions does not exceed three.

NOTE 3 A session used for decrypting a command parameter may also be used for encrypting a response parameter.

ii) If a session is not being used for authorization, at least one of decrypt, encrypt, or audit must be SET. (TPM_RC_ATTRIBUTES).

5) An authorization session is present for each of the handles with the “@” decoration (TPM_RC_AUTH_MISSING).

5.6 Authorization Checks

After unmarshaling and validating the handles and the consistency of the authorization sessions, the authorizations shall be checked. Authorization checks only apply to handles if the handle in the command schematic has the “@” decoration. Authorization checks must be performed in this order.

a) The public and sensitive portions of the object shall be present on the TPM (TPM_RC_AUTH_UNAVAILABLE).

b) If the associated handle is TPM_RH_PLATFORM, and the command requires confirmation with physical presence, then physical presence is asserted (TPM_RC_PP).

c) If the object or NV Index is subject to DA protection, and the authorization is with an HMAC or password, then the TPM is not in lockout (TPM_RC_LOCKOUT).

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

NOTE 1 An object is subject to DA protection if its *noDA* attribute is CLEAR. An NV Index is subject to DA protection if its TPMA_NV_NO_DA attribute is CLEAR.

NOTE 2 An HMAC or password is required in a policy session when the policy contains TPM2_PolicyAuthValue() or TPM2_PolicyPassword().

d) If the command requires a handle to have DUP role authorization, then the associated authorization session is a policy session (TPM_RC_AUTH_TYPE).

e) If the command requires a handle to have ADMIN role authorization:

1) If the entity being authorized is an object and its *adminWithPolicy* attribute is SET, or a hierarchy, then the authorization session is a policy session (TPM_RC_AUTH_TYPE).

NOTE 3 If adminWithPolicy is CLEAR, then any type of authorization session is allowed.

2) If the entity being authorized is an NV Index, then the associated authorization session is a policy session.

NOTE 4 The only commands that are currently defined that require use of ADMIN role authorization are commands that operate on objects and NV Indices.

f) If the command requires a handle to have USER role authorization:

1) If the entity being authorized is an object and its *userWithAuth* attribute is CLEAR, then the associated authorization session is a policy session (TPM_RC_POLICY_FAIL).

NOTE 5 There is no check for a hierarchy, because a hierarchy operates as if userWithAuth is SET.

2) If the entity being authorized is an NV Index;

i) if the authorization session is a policy session;

(a) the TPMA_NV_POLICYWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

(b) the TPMA_NV_POLICYREAD attribute of the NV Index is SET if the command reads the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

ii) if the authorization is an HMAC session or a password;

(a) the TPMA_NV_AUTHWRITE attribute of the NV Index is SET if the command modifies the NV Index data (TPM_RC_AUTH_UNAVAILABLE);

(b) the TPMA_NV_AUTHREAD attribute of the NV Index is SET if the command reads the NV Index data (TPM_RC_AUTH_UNAVAILABLE).

g) If the authorization is provided by a policy session, then:

1) if *policySession→timeOut* has been set, the session shall not have expired (TPM_RC_EXPIRED);

2) if *policySession→cpHash* has been set, it shall match the *cpHash* of the command (TPM_RC_POLICY_FAIL);

3) if *policySession→commandCode* has been set, then *commandCode* of the command shall match (TPM_RC_POLICY_CC);

4) *policySession→policyDigest* shall match the *authPolicy* associated with the handle (TPM_RC_POLICY_FAIL);

5) if *policySession→pcrUpdateCounter* has been set, then it shall match the value of *pcrUpdateCounter* (TPM_RC_PCR_CHANGED);

6) if *policySession→commandLocality* has been set, it shall match the locality of the command (TPM_RC_LOCALITY),

November 8, 2019 Copyright © TCG 2006-2020 Level 00 Revision 01.59

7) if *policySession→cpHash* contains a template, and the command is TPM2_Create(), TPM2_CreatePrimary(), or TPM2_CreateLoaded(), then the *inPublic* parmeter matches the contents of *policySession→cpHash;* and

8) if the policy requires that an authValue be provided in order to satisfy the policy, then *session.hmac* is not an Empty Buffer.

h) If the authorization uses an HMAC, then the HMAC is properly constructed using the *authValue* associated with the handle and/or the session secret (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

NOTE 6 A policy session may require proof of knowledge of the authValue of the object being authorized.

i) If the authorization uses a password, then the password matches the *authValue* associated with the handle (TPM_RC_AUTH_FAIL or TPM_RC_BAD_AUTH).

If the TPM returns an error other than TPM_RC_AUTH_FAIL then the TPM shall not alter any TPM state. If the TPM return TPM_RC_AUTH_FAIL, then the TPM shall not alter any TPM state other than *lockoutCount*.

NOTE 7 The TPM may decrease failedTries regardless of any other processing performed by the TPM. That is, the TPM may exit Lockout mode, regardless of the return code.

5.7 Parameter Decryption

If an authorization session has the TPMA_SESSION.*decrypt* attribute SET, and the command does not allow a command parameter to be encrypted, then the TPM will return TPM_RC_ATTRIBUTES. Otherwise, the TPM will decrypt the parameter using the values associated with the session before parsing parameters.

NOTE The size of the parameter to be encrypted can be zero.

5.8 Parameter Unmarshaling

5.8.1 Introduction

The detailed actions for each command assume that the input parameters of the command have been unmarshaled into a command-specific structure with the structure defined by the command schematic. Additionally, a response-specific output structure is assumed which will receive the values produced by the detailed actions.

NOTE An implementation is not required to process parameters in this manner or to separate the parameter parsing from the command actions. This method was chosen for the specification so that the normative behavior described by the detailed actions would be clear and unencumbered.

Unmarshaling is the process of processing the parameters in the input buffer and preparing the parameters for use by the command-specific action code. No data movement need take place but it is required that the TPM validate that the parameters meet the requirements of the expected data type as defined in TPM 2.0 Part 2.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

5.8.2 Unmarshaling Errors

When an error is encountered while unmarshaling a command parameter, an error response code is returned and no command processing occurs. A table defining a data type may have response codes embedded in the table to indicate the error returned when the input value does not match the parameters of the table.

NOTE In the reference implementation, a parameter number is added to the response code so that the offending parameter can be isolated. This is optional.

In many cases, the table contains no specific response code value and the return code will be determined as defined in Table 3.

Table 3 — Unmarshaling Errors

Response Code	Meaning
TPM_RC_ASYMMETRIC	a parameter that should be an asymmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_BAD_TAG	a parameter that should be a command tag selection has a value that is not supported by the TPM
TPM_RC_COMMAND_CODE	a parameter that should be a command code does not have a value that is supported by the TPM
TPM_RC_HASH	a parameter that should be a hash algorithm selection does not have a value that is supported by the TPM
TPM_RC_INSUFFICIENT	the input buffer did not contain enough octets to allow unmarshaling of the expected data type;
TPM_RC_KDF	a parameter that should be a key derivation scheme (KDF) selection does not have a value that is supported by the TPM
TPM_RC_KEY_SIZE	a parameter that is a key size has a value that is not supported by the TPM
TPM_RC_MODE	a parameter that should be a symmetric encryption mode selection does not have a value that is supported by the TPM
TPM_RC_RESERVED	a non-zero value was found in a reserved field of an attribute structure (TPMA_)
TPM_RC_SCHEME	a parameter that should be signing or encryption scheme selection does not have a value that is supported by the TPM
TPM_RC_SIZE	the value of a size parameter is larger or smaller than allowed
TPM_RC_SYMMETRIC	a parameter that should be a symmetric algorithm selection does not have a value that is supported by the TPM
TPM_RC_TAG	a parameter that should be a structure tag has a value that is not supported by the TPM
TPM_RC_TYPE	The type parameter of a TPMT_PUBLIC or TPMT_SENSITIVE has a value that is not supported by the TPM
TPM_RC_VALUE	a parameter does not have one of its allowed values

In some commands, a parameter may not be used because of various options of that command. However, the unmarshaling code is required to validate that all parameters have values that are allowed by the TPM 2.0 Part 2 definition of the parameter type even if that parameter is not used in the command actions.

 Copyright © TCG 2006-2020

5.9 Command Post Processing

When the code that implements the detailed actions of the command completes, it returns a response code. If that code is not TPM_RC_SUCCESS, the post processing code will not update any session or audit data and will return a 10-octet response packet.

If the command completes successfully, the tag of the command determines if any authorization sessions will be in the response. If so, the TPM will encrypt the first parameter of the response if indicated by the authorization attributes. The TPM will then generate a new nonce value for each session and, if appropriate, generate an HMAC.

If authorization HMAC computations are performed on the response, the HMAC keys used in the response will be the same as the HMAC keys used in processing the HMAC in the command.

NOTE 1 This primarily affects authorizations associated with a first write to an NV Index using a bound session. The computation of the HMAC in the response is performed as if the Name of the Index did not change as a consequence of the command actions. The session binding to the NV Index will not persist to any subsequent command.

NOTE 2 The authorization attributes were validated during the session area validation to ensure that only one session was used for parameter encryption of the response and that the command allowed encryption in the response.

NOTE 3 No session nonce value is used for a password authorization but the session data is present.

Additionally, if the command is being audited by Command Audit, the audit digest is updated with the *cpHash* of the command and *rpHash* of the response.

 Copyright © TCG 2006-2020

6 Response Values

6.1 Tag

When a command completes successfully, the *tag* parameter in the response shall have the same value as the *tag* parameter in the command (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). When a command fails (the responseCode is not TPM_RC_SUCCESS), then the *tag* parameter in the response shall be TPM_ST_NO_SESSIONS.

A special case exists when the command *tag* parameter is not an allowed value (TPM_ST_SESSIONS or TPM_ST_NO_SESSIONS). For this case, it is assumed that the system software is attempting to send a command formatted for a TPM 1.2 but the TPM is not capable of executing TPM 1.2 commands. So that the TPM 1.2 compatible software will have a recognizable response, the TPM sets *tag* to TPM_ST_RSP_COMMAND, *responseSize* to 00 00 00 $0A_{16}$ and *responseCode* to TPM_RC_BAD_TAG. This is the same response as the TPM 1.2 fatal error for TPM_BADTAG.

6.2 Response Codes

The normal response for any command is TPM_RC_SUCCESS. Any other value indicates that the command did not complete and the state of the TPM is unchanged. An exception to this general rule is that the logic associated with dictionary attack protection is allowed to be modified when an authorization failure occurs.

Commands have response codes that are specific to that command, and those response codes are enumerated in the detailed actions of each command. The codes associated with the unmarshaling of parameters are documented Table 3. Another set of response code values are not command specific and indicate a problem that is not specific to the command. That is, if the indicated problem is remedied, the same command could be resubmitted and may complete normally.

The response codes that are not command specific are listed and described in

Table 4.

The reference code for the command actions may have code that generates specific response codes associated with a specific check but the listing of responses may not have that response code listed.

 Copyright © TCG 2006-2020

Table 4 — Command-Independent Response Codes

Response Code	Meaning
TPM_RC_CANCELED	This response code may be returned by a TPM that supports command cancel. When the TPM receives an indication that the current command should be cancelled, the TPM may complete the command or return this code. If this code is returned, then the TPM state is not changed and the same command may be retried.
TPM_RC_CONTEXT_GAP	This response code can be returned for commands that manage session contexts. It indicates that the gap between the lowest numbered active session and the highest numbered session is at the limits of the session tracking logic. The remedy is to load the session context with the lowest number so that its tracking number can be updated.
TPM_RC_LOCKOUT	This response indicates that authorizations for objects subject to DA protection are not allowed at this time because the TPM is in DA lockout mode. The remedy is to wait or to exeucte TPM2_DictionaryAttackLockoutReset().
TPM_RC_MEMORY	A TPM may use a common pool of memory for objects, sessions, and other purposes. When the TPM does not have enough memory available to perform the actions of the command, it may return TPM_RC_MEMORY. This indicates that the TPM resource manager may flush either sessions or objects in order to make memory available for the command execution. A TPM may choose to return TPM_RC_OBJECT_MEMORY or TPM_RC_SESSION_MEMORY if it needs contexts of a particular type to be flushed.
TPM_RC_NV_RATE	This response code indicates that the TPM is rate-limiting writes to the NV memory in order to prevent wearout. This response is possible for any command that explicity writes to NV or commands that incidentally use NV such as a command that uses authorization session that may need to update the dictionary attack logic.
TPM_RC_NV_UNAVAILABLE	This response code is similar to TPM_RC_NV_RATE but indicates that access to NV memory is currently not available and the command is not allowed to proceed until it is. This would occur in a system where the NV memory used by the TPM is not exclusive to the TPM and is a shared system resource.
TPM_RC_OBJECT_HANDLES	This response code indicates that the TPM has exhausted its handle space and no new objects can be loaded unless the TPM is rebooted. This does not occur in the reference implementation because of the way that object handles are allocated. However, other implementations are allowed to assign each object a unique handle each time the object is loaded. A TPM using this implementation would be able to load 2^{24} objects before the object space is exhausted.
TPM_RC_OBJECT_MEMORY	This response code can be returned by any command that causes the TPM to need an object 'slot'. The most common case where this might be returned is when an object is loaded (TPM2_Load, TPM2_CreatePrimary(), or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other reasons. In the reference implementation, the TPM copies a referenced persistent object into RAM for the duration of the commannd. If all the slots are previously occupied, the TPM may return this value. A TPM is allowed to use object slots for other purposes and return this value. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_REFERENCE_Hx	This response code indicates that a handle in the handle area of the command is not associated with a loaded object. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1st handle and 6 representing the 7th. Upper values are provided for future use. The TPM resource manager needs to find the correct object and load it. It may then adjust the handle and retry the command. NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

Response Code	Meaning
TPM_RC_REFERENCE_Sx	This response code indicates that a handle in the session area of the command is not associated with a loaded session. The value of 'x' is in the range 0 to 6 with a value of 0 indicating the 1st session handle and 6 representing the 7th. Upper values are provided for future use. The TPM resource manager needs to find the correct session and load it. It may then retry the command. NOTE Usually, this error indicates that the TPM resource manager has a corrupted database.
TPM_RC_RETRY	the TPM was not able to start the command
TPM_RC_SESSION_HANDLES	This response code indicates that the TPM does not have a handle to assign to a new session. This respose is only returned by TPM2_StartAuthSession(). It is listed here because the command is not in error and the TPM resource manager can remedy the situation by flushing a session (TPM2_FlushContext().
TPM_RC_SESSION_MEMORY	This response code can be returned by any command that causes the TPM to need a session 'slot'. The most common case where this might be returned is when a session is loaded (TPM2_StartAuthSession() or TPM2_ContextLoad()). However, the TPM implementation is allowed to use object slots for other purposes. The remedy when this response is returned is for the TPM resource manager to flush a transient object.
TPM_RC_SUCCESS	Normal completion for any command. If the responseCode is TPM_RC_SUCCESS, then the rest of the response has the format indicated in the response schematic. Otherwise, the response is a 10 octet value indicating an error.
TPM_RC_TESTING	This response code indicates that the TPM is performing tests and cannot respond to the request at this time. The command may be retried.
TPM_RC_YIELDED	the TPM has suspended operation on the command; forward progress was made and the command may be retried. See TPM 2.0 Part 1, “Multi-tasking.” NOTE This cannot occur on the reference implementation.

7 Implementation Dependent

The actions code for each command makes assumptions about the behavior of various sub-systems. There are many possible implementations of the subsystems that would achieve equivalent results. The actions code is not written to anticipate all possible implementations of the sub-systems. Therefore, it is the responsibility of the implementer to ensure that the necessary changes are made to the actions code when the sub-system behavior changes.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

8 Detailed Actions Assumptions

8.1 Introduction

The C code in the Detailed Actions for each command is written with a set of assumptions about the processing performed before the action code is called and the processing that will be done after the action code completes.

8.2 Pre-processing

Before calling the command actions code, the following actions have occurred.

- Verification that the handles in the handle area reference entities that are resident on the TPM.
- NOTE If a handle is in the parameter portion of the command, the associated entity does not have to be loaded, but the handle is required to be the correct type.
- If use of a handle requires authorization, the Password, HMAC, or Policy session associated with the handle has been verified.
- If a command parameter was encrypted using parameter encryption, it was decrypted before being unmarshaled.
- If the command uses handles or parameters, the calling stack contains a pointer to a data structure (*in*) that holds the unmarshaled values for the handles and command parameters. If the response has handles or parameters, the calling stack contains a pointer to a data structure (*out*) to hold the handles and response parameters generated by the command.
- All parameters of the *in* structure have been validated and meet the requirements of the parameter type as defined in TPM 2.0 Part 2.
- Space set aside for the out structure is sufficient to hold the largest *out* structure that could be produced by the command

8.3 Post Processing

When the function implementing the command actions completes,

- response parameters that require parameter encryption will be encrypted after the command actions complete;
- audit and session contexts will be updated if the command response is TPM_RC_SUCCESS; and
- the command header and command response parameters will be marshaled to the response buffer.

9 Start-up

9.1 Introduction

This clause contains the commands used to manage the startup and restart state of a TPM.

9.2 _TPM_Init

9.2.1 General Description

_TPM_Init initializes a TPM.

Initialization actions include testing code required to execute the next expected command. If the TPM is in FUM, the next expected command is TPM2_FieldUpgradeData(); otherwise, the next expected command is TPM2_Startup().

NOTE 1 If the TPM performs self-tests after receiving _TPM_Init() and the TPM enters Failure mode before receiving TPM2_Startup() or TPM2_FieldUpgradeData(), then the TPM may be able to accept TPM2_GetTestResult() or TPM2_GetCapability().

The means of signaling _TPM_Init shall be defined in the platform-specific specifications that define the physical interface to the TPM. The platform shall send this indication whenever the platform starts its boot process and only when the platform starts its boot process.

There shall be no software method of generating this indication that does not also reset the platform and begin execution of the CRTM.

NOTE 2 In the reference implementation, this signal causes an internal flag (*s_initialized*) to be CLEAR. While this flag is CLEAR, the TPM will only accept the next expected command described above.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

9.2.2 Detailed Actions

[[_TPM_Init]]

9.3 TPM2_Startup

9.3.1 General Description

TPM2_Startup() is always preceded by _TPM_Init, which is the physical indication that TPM initialization is necessary because of a system-wide reset. TPM2_Startup() is only valid after _TPM_Init. Additional TPM2_Startup() commands are not allowed after it has completed successfully. If a TPM requires TPM2_Startup() and another command is received, or if the TPM receives TPM2_Startup() when it is not required, the TPM shall return TPM_RC_INITIALIZE.

NOTE 1 See 9.2.1 for other command options for a TPM supporting field upgrade mode.

NOTE 2 _TPM_Hash_Start, _TPM_Hash_Data, and _TPM_Hash_End are not commands and a platform-specific specification may allow these indications between _TPM_Init and TPM2_Startup().

If in Failure mode, the TPM shall accept TPM2_GetTestResult() and TPM2_GetCapability() even if TPM2_Startup() is not completed successfully or processed at all.

A platform-specific specification may restrict the localities at which TPM2_Startup() may be received.

A Shutdown/Startup sequence determines the way in which the TPM will operate in response to TPM2_Startup(). The three sequences are:

1) TPM Reset – This is a Startup(CLEAR) preceded by either Shutdown(CLEAR) or no TPM2_Shutdown(). On TPM Reset, all variables go back to their default initialization state.

   NOTE 3 Only those values that are specified as having a default initialization state are changed by TPM Reset. Persistent values that have no default initialization state are not changed by this command. Values such as seeds have no default initialization state and only change due to specific commands.

2) TPM Restart – This is a Startup(CLEAR) preceded by Shutdown(STATE). This preserves much of the previous state of the TPM except that PCR and the controls associated with the Platform hierarchy are all returned to their default initialization state;

3) TPM Resume – This is a Startup(STATE) preceded by Shutdown(STATE). This preserves the previous state of the TPM including the static Root of Trust for Measurement (S-RTM) PCR and the platform controls other than the *phEnable*.

If a TPM receives Startup(STATE) and that was not preceded by Shutdown(STATE), the TPM shall return TPM_RC_VALUE.

If, during TPM Restart or TPM Resume, the TPM fails to restore the state saved at the last Shutdown(STATE), the TPM shall enter Failure Mode and return TPM_RC_FAILURE.

On any TPM2_Startup(),

- *phEnable* shall be SET;
- all transient contexts (objects, sessions, and sequences) shall be flushed from TPM memory;

NOTE 4 See Part 1 Time for a description of the TPMS_TIME_INFO.*time* behaviour.

- use of *lockoutAuth* shall be enabled if *lockoutRecovery* is zero.

Additional actions are performed based on the Shutdown/Startup sequence.

 Copyright © TCG 2006-2020

On TPM Reset:

- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- For each NV Index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV Index with TPMA_NV_ORDERLY SET, TPMA_NV_WRITTEN shall be CLEAR unless the type is TPM_NT_COUNTER,
- On a disorderly reset, advance the orderly counters,
- For each NV Index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR,
- tracking data for saved session contexts shall be set to its initial value,
- the object context sequence number is reset to zero,
- a new context encryption key shall be generated,
- TPMS_CLOCK_INFO.*restartCount* shall be reset to zero,
- TPMS_CLOCK_INFO.*resetCount* shall be incremented,
- the PCR Update Counter shall be clear to zero,

  NOTE 5 Because the PCR update counter may be incremented when a PCR is reset, the PCR resets performed as part of this command can result in the PCR update counter being non-zero at the end of this command.

- *phEnableNV, shEnable* and *ehEnable* shall be SET, and
- PCR in all banks are reset to their default initial conditions as determined by the relevant platform-specific specification and the H-CRTM state (for exceptions, see TPM 2.0 Part 1*, H-CRTM before TPM2_Startup() and TPM2_Startup without H-CRTM*),
- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR (if *preserveSignaled* is CLEAR), and the *authPolicy* is set to the Empty Buffer and its hashAlg is set to TPM_ALG_NULL.

  NOTE 6 PCR may be initialized any time between _TPM_Init and the end of TPM2_Startup(). PCR that are preserved by TPM Resume will need to be restored during TPM2_Startup().

  NOTE 7 See "Initializing PCR" in TPM 2.0 Part 1 for a description of the default initial conditions for a PCR.

 Copyright © TCG 2006-2020

On TPM Restart:

- TPMS_CLOCK_INFO.*restartCount* shall be incremented,
- *phEnableNV, shEnable* and *ehEnable* shall be SET,
- *platformAuth* and *platformPolicy* shall be set to the Empty Buffer,
- For each NV index with TPMA_NV_WRITEDEFINE CLEAR or TPMA_NV_WRITTEN CLEAR, TPMA_NV_WRITELOCKED shall be CLEAR,
- For each NV index with TPMA_NV_CLEAR_STCLEAR SET, TPMA_NV_WRITTEN shall be CLEAR, and
- PCR in all banks are reset to their default initial conditions.
- If an H-CRTM Event Sequence is active, extend the PCR designated by the platform-specific specification.
- For each ACT the timeout is reset to zero, the *signaled* attribute is set to CLEAR (if *preserveSignaled* is CLEAR), and the *authPolicy* is set to the Empty Buffer and its hashAlg is set to TPM_ALG_NULL.

On TPM Resume:

- the H-CRTM startup method is the same for this TPM2_Startup() as for the previous TPM2_Startup(); (TPM_RC_LOCALITY)
- TPMS_CLOCK_INFO.*restartCount* shall be incremented; and
- PCR that are specified in a platform-specific specification to be preserved on TPM Resume are restored to their saved state and other PCR are set to their initial value as determined by a platform-specific specification. For constraints, see TPM 2.0 Part 1, *H-CRTM before TPM2_Startup() and TPM2_Startup without H-CRTM.*
- The ACT timeout, the ACT *signaled* attribute and the ACT specific *authPolicy* values are preserved.

Other TPM state may change as required to meet the needs of the implementation.

If the *startupType* is TPM_SU_STATE and the TPM requires TPM_SU_CLEAR, then the TPM shall return TPM_RC_VALUE.

NOTE 8 The TPM will require TPM_SU_CLEAR when no shutdown was performed or after Shutdown(CLEAR).

NOTE 9 If *startupType* is neither TPM_SU_STATE nor TPM_SU_CLEAR, then the unmarshaling code returns TPM_RC_VALUE.

9.4 TPM2_Shutdown

9.4.1 General Description

This command is used to prepare the TPM for a power cycle. The *shutdownType* parameter indicates how the subsequent TPM2_Startup() will be processed.

For a *shutdownType* of any type, the volatile portion of Clock is saved to NV memory and the orderly shutdown indication is SET. NV Indexes with the TPMA_NV_ORDERLY attribute will be updated.

For a *shutdownType* of TPM_SU_STATE, the following additional items are saved:

- tracking information for saved session contexts;
- the session context counter;
- PCR that are designated as being preserved by TPM2_Shutdown(TPM_SU_STATE);
- the PCR Update Counter;
- flags associated with supporting the TPMA_NV_WRITESTCLEAR and TPMA_NV_READSTCLEAR attributes;
- the counter value and authPolicy for each ACT; and

  NOTE If a counter has not been updated since the last TPM2_Startup(), then the saved value will be one half of the current counter value.

- the command audit digest and count.

The following items shall not be saved and will not be in TPM memory after the next TPM2_Startup:

- TPM-memory-resident session contexts;
- TPM-memory-resident transient objects; or
- TPM-memory-resident hash contexts created by TPM2_HashSequenceStart().

Some values may be either derived from other values or saved to NV memory.

This command saves TPM state but does not change the state other than the internal indication that the context has been saved. The TPM shall continue to accept commands. If a subsequent command changes TPM state saved by this command, then the effect of this command is nullified. The TPM MAY nullify this command for any subsequent command rather than check whether the command changed state saved by this command. If this command is nullified. and if no TPM2_Shutdown() occurs before the next TPM2_Startup(), then the next TPM2_Startup() shall be TPM2_Startup(CLEAR).

[[Shutdown]]

10 Testing

10.1 Introduction

Compliance to standards for hardware security modules may require that the TPM test its functions before the results that depend on those functions may be returned. The TPM may perform operations using testable functions before those functions have been tested as long as the TPM returns no value that depends on the correctness of the testable function.

EXAMPLE TPM2_PCR_Extend() may be executed before the hash algorithms have been tested. However, until the hash algorithms have been tested, the contents of a PCR may not be used in any command if that command may result in a value being returned to the TPM user. This means that TPM2_PCR_Read() or TPM2_PolicyPCR() could not complete until the hashes have been checked but other TPM2_PCR_Extend() commands may be executed even though the operation uses previous PCR values.

If a command is received that requires return of a value that depends on untested functions, the TPM shall test the required functions before completing the command.

Once the TPM has received TPM2_SelfTest() and before completion of all tests, the TPM is required to return TPM_RC_TESTING for any command that uses a function that requires a test.

If a self-test fails at any time, the TPM will enter Failure mode. While in Failure mode, the TPM will return TPM_RC_FAILURE for any command other than TPM2_GetTestResult() and TPM2_GetCapability(). The TPM will remain in Failure mode until the next _TPM_Init.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

10.2 TPM2_SelfTest

10.2.1 General Description

This command causes the TPM to perform a test of its capabilities. If the *fullTest* is YES, the TPM will test all functions. If *fullTest* = NO, the TPM will only test those functions that have not previously been tested.

If any tests are required, the TPM shall either

- return TPM_RC_TESTING and begin self-test of the required functions, or

  NOTE 1 If *fullTest* is NO, and all functions have been tested, the TPM shall return TPM_RC_SUCCESS.

- perform the tests and return the test result when complete. On failure, the TPM shall return TPM_RC_FAILURE.

If the TPM uses option a), the TPM shall return TPM_RC_TESTING for any command that requires use of a testable function, even if the functions required for completion of the command have already been tested.

NOTE 2 This command may cause the TPM to continue processing after it has returned the response. So that software can be notified of the completion of the testing, the interface may include controls that would allow the TPM to generate an interrupt when the "background" processing is complete. This would be in addition to the interrupt that may be available for signaling normal command completion. It is not necessary that there be two interrupts, but the interface should provide a way to indicate the nature of the interrupt (normal command or deferred command).

NOTE 3 The PC Client platform specific TPM, in response to *fullTest* YES, will not return TPM_RC_TESTING. It will block until all tests are complete.

10.2.3 Detailed Actions

[[SelfTest]]

10.3 TPM2_IncrementalSelfTest

10.3.1 General Description

This command causes the TPM to perform a test of the selected algorithms.

NOTE 1 The *toTest* list indicates the algorithms that software would like the TPM to test in anticipation of future use. This allows tests to be done so that a future commands will not be delayed due to testing.

The implementation may treat algorithms on the *toTest* list as either 'test each completely' or 'test this combination.'

EXAMPLE If the *toTest* list includes AES and CTR mode, it may be interpreted as a request to test only AES in CTR mode. Alternatively, it may be interpreted as a request to test AES in all modes and CTR mode for all symmetric algorithms.

If *toTest* contains an algorithm that has already been tested, it will not be tested again.

NOTE 2 The only way to force retesting of an algorithm is with TPM2_SelfTest(*fullTest* = YES).

The TPM will return in *toDoList* a list of algorithms that are yet to be tested. This list is not the list of algorithms that are scheduled to be tested but the algorithms/functions that have not been tested. Only the algorithms on the *toTest* list are scheduled to be tested by this command.

NOTE 3 An algorithm remains on the *toDoList* while any part of it remains untested.

EXAMPLE A symmetric algorithm remains untested until it is tested with all its modes.

Making *toTest* an empty list allows the determination of the algorithms that remain untested without triggering any testing.

If *toTest* is not an empty list, the TPM shall return TPM_RC_SUCCESS for this command and then return TPM_RC_TESTING for any subsequent command (including TPM2_IncrementalSelfTest()) until the requested testing is complete.

NOTE 4 If *toDoList* is empty, then no additional tests are required and TPM_RC_TESTING will not be returned in subsequent commands and no additional delay will occur in a command due to testing.

NOTE 5 If none of the algorithms listed in *toTest* is in the *toDoList*, then no tests will be performed.

NOTE 6 The TPM cannot return TPM_RC_TESTING for the first call to this command even when testing is not complete, because response parameters can only returned with the TPM_RC_SUCCESS return code.

If all the parameters in this command are valid, the TPM returns TPM_RC_SUCCESS and the *toDoList* (which may be empty).

NOTE 7 An implementation may perform all requested tests before returning TPM_RC_SUCCESS, or it may return TPM_RC_SUCCESS for this command and then return TPM_RC_TESTING for all subsequence commands (including TPM2_IncrementatSelfTest()) until the requested tests are complete.

10.3.3 Detailed Actions

[[IncrementalSelfTest]]

10.4 TPM2_GetTestResult

10.4.1 General Description

This command returns manufacturer-specific information regarding the results of a self-test and an indication of the test status.

If TPM2_SelfTest() has not been executed and a testable function has not been tested, *testResult* will be TPM_RC_NEEDS_TEST. If TPM2_SelfTest() has been received and the tests are not complete, *testResult* will be TPM_RC_TESTING.

If testing of all functions is complete without functional failures, *testResult* will be TPM_RC_SUCCESS. If any test failed, *testResult* will be TPM_RC_FAILURE.

This command will operate when the TPM is in Failure mode so that software can determine the test status of the TPM and so that diagnostic information can be obtained for use in failure analysis. If the TPM is in Failure mode, then *tag* is required to be TPM_ST_NO_SESSIONS or the TPM shall return TPM_RC_FAILURE.

NOTE The reference implementation may return a 32-bit value *s_failFunction*. This simply gives a unique value to each of the possible places where a failure could occur. It is not intended to provide a pointer to the function. __func__ is a pointer to a character string but the failure mode code can only return 32-bit values. It is expected that the manufacturer can disambiguate this value if a customer's TPM goes into failure mode.

10.4.3 Detailed Actions

[[GetTestResult]]

11 Session Commands

11.1 TPM2_StartAuthSession

11.1.1 General Description

This command is used to start an authorization session using alternative methods of establishing the session key (*sessionKey*). The session key is then used to derive values used for authorization and for encrypting parameters.

This command allows injection of a secret into the TPM using either asymmetric or symmetric encryption. The type of *tpmKey* determines how the value in *encryptedSalt* is encrypted. The decrypted secret value is used to compute the *sessionKey*.

NOTE 1 If *tpmKey* Is TPM_RH_NULL, then *encryptedSalt* is required to be an Empty Buffer.

The label value of “SECRET” (see “Terms and Definitions” in TPM 2.0 Part 1) is used in the recovery of the secret value.

The TPM generates the *sessionKey* from the recovered secret value.

No authorization is required for *tpmKey* or *bind*.

NOTE 2 The justification for using *tpmKey* without providing authorization is that the result of using the key is not available to the caller, except indirectly through the *sessionKey*. This does not represent a point of attack on the value of the key. If the caller attempts to use the session without knowing the *sessionKey* value, it is an authorization failure that will trigger the dictionary attack logic.

The entity referenced with the *bind* parameter contributes an authorization value to the *sessionKey* generation process.

If both *tpmKey* and *bind* are TPM_RH_NULL, then *sessionKey* is set to the Empty Buffer. If *tpmKey* is not TPM_RH_NULL, then *encryptedSalt* is used in the computation of *sessionKey*. If *bind* is not TPM_RH_NULL, the *authValue* of *bind* is used in the *sessionKey* computation.

If *symmetric* specifies a block cipher, then TPM_ALG_CFB is the only allowed value for the *mode* field in the *symmetric* parameter (TPM_RC_MODE).

This command starts an authorization session and returns the session handle along with an initial *nonceTPM* in the response.

If the TPM does not have a free slot for an authorization session, it shall return TPM_RC_SESSION_HANDLES.

If the TPM implements a “gap” scheme for assigning *contextID* values, then the TPM shall return TPM_RC_CONTEXT_GAP if creating the session would prevent recycling of old saved contexts (See “Context Management” in TPM 2.0 Part 1).

If *tpmKey* is not TPM_ALG_NULL then *encryptedSalt* shall be a TPM2B_ENCRYPTED_SECRET of the proper type for *tpmKey*. The TPM shall return TPM_RC_HANDLE if the sensitive portion of *tpmKey* is not loaded. The TPM shall return TPM_RC_VALUE if:

a) *tpmKey* references an RSA key and
   1) the size of *encryptedSalt* is not the same as the size of the public modulus of *tpmKey*,
   2) *encryptedSalt* has a value that is greater than the public modulus of *tpmKey*,
   3) *encryptedSalt* is not a properly encoded OAEP value, or
   4) the decrypted *salt* value is larger than the size of the digest produced by the *nameAlg* of *tpmKey*; or

 Copyright © TCG 2006-2020

NOTE 3 The asymScheme of the key object is ignored in this case and TPM_ALG_OAEP is used, even if asymScheme is set to TPM_ALG_NULL.

b) *tpmKey* references an ECC key and *encryptedSalt*

1) does not contain a TPMS_ECC_POINT or

2) is not a point on the curve of *tpmKey*;

NOTE 4 When ECC is used, the point multiply process produces a value (Z) that is used in a KDF to produce the final secret value. The size of the secret value is an input parameter to the KDF and the result will be set to be the size of the digest produced by the *nameAlg* of *tpmKey*.

The TPM shall return TPM_RC_KEY if *tpmkey* does not reference an asymmetric key. The TPM shall return TPM_RC_VALUE if the scheme of the key is not TPM_ALG_OAEP or TPM_ALG_NULL. The TPM shall return TPM_RC_ATTRIBUTES if tpmKey does not have the *decrypt* attribute SET.

NOTE While TPM_RC_VALUE is preferred, TPM_RC_SCHEME is acceptable.

If *bind* references a transient object, then the TPM shall return TPM_RC_HANDLE if the sensitive portion of the object is not loaded.

For all session types, this command will cause initialization of the *sessionKey* and may establish binding between the session and an object (the *bind* object). If *sessionType* is TPM_SE_POLICY or TPM_SE_TRIAL, the additional session initialization is:

- set *policySession→policyDigest* to a Zero Digest (the digest size for *policySession→policyDigest* is the size of the digest produced by *authHash*);
- authorization may be given at any locality;
- authorization may apply to any command code;
- authorization may apply to any command parameters or handles;
- the authorization has no time limit;
- an authValue is not needed when the authorization is used;
- the session is not bound;
- the session is not an audit session; and
- the time at which the policy session was created is recorded.

Additionally, if *sessionType* is TPM_SE_TRIAL, the session will not be usable for authorization but can be used to compute the *authPolicy* for an object.

NOTE 5 Although this command changes the session allocation information in the TPM, it does not invalidate a saved context. That is, TPM2_Shutdown() is not required after this command in order to re-establish the orderly state of the TPM. This is because the created context will occupy an available slot in the TPM and sessions in the TPM do not survive any TPM2_Startup(). However, if a created session is context saved, the orderly state does change.

The TPM shall return TPM_RC_SIZE if *nonceCaller* is less than 16 octets or is greater than the size of the digest produced by *authHash*.

11.1.3 Detailed Actions

[[StartAuthSession]]

11.2 TPM2_PolicyRestart

11.2.1 General Description

This command allows a policy authorization session to be returned to its initial state. This command is used after the TPM returns TPM_RC_PCR_CHANGED. That response code indicates that a policy will fail because the PCR have changed after TPM2_PolicyPCR() was executed. Restarting the session allows the authorizations to be replayed because the session restarts with the same *nonceTPM*. If the PCR are valid for the policy, the policy may then succeed.

This command does not reset the policy ID or the policy start time.

12 Object Commands

12.1 TPM2_Create

12.1.1 General Description

This command is used to create an object that can be loaded into a TPM using TPM2_Load(). If the command completes successfully, the TPM will create the new object and return the object's creation data (*creationData*), its public area (*outPublic*), and its encrypted sensitive area (*outPrivate*). Preservation of the returned data is the responsibility of the caller. The object will need to be loaded (TPM2_Load()) before it may be used. The only difference between the *inPublic* TPMT_PUBLIC template and the *outPublic* TPMT_PUBLIC object is in the *unique* field.

NOTE 1 This command may require temporary use of a transient resource, even though the object does not remain loaded after the command. See Part 1 Transient Resources.

TPM2B_PUBLIC template (*inPublic*) contains all of the fields necessary to define the properties of the new object. The setting for these fields is defined in "Public Area Template" in Part 1 of this specification and in "TPMA_OBJECT" in Part 2 of this specification. The size of the *unique* field shall not be checked for consistency with the other object parameters.

NOTE 2 For interoperability, the *unique* field should not be set to a value that is larger than allowed by object parameters, so that the unmarshaling will not fail. A size of zero is recommended. After unmarshaling, the TPM does not use the input *unique* field. It is, however, used in TPM2_CreatePrimary() and TPM2_CreateLoaded.

EXAMPLE 1 A TPM_ALG_RSA object with a *keyBits* of 2048 in the object's parameters should have a *unique* field that is no larger than 256 bytes.

EXAMPLE 2 TPM_ALG_KEYEDHASH or a TPM_ALG_SYMCIPHER object should have a *unique* field that is no larger than the digest produced by the object's *nameAlg*.

The *parentHandle* parameter shall reference a loaded decryption key that has both the public and sensitive area loaded.

When defining the object, the caller provides a template structure for the object in a TPM2B_PUBLIC structure (*inPublic*), an initial value for the object's *authValue (inSensitive.userAuth),* and, if the object is a symmetric object, an optional initial data value (*inSensitive.data*). The TPM shall validate the consistency of the attributes of *inPublic* according to the Creation rules in "TPMA_OBJECT" in TPM 2.0 Part 2.

The *inSensitive* parameter may be encrypted using parameter encryption.

The methods in this clause are used by both TPM2_Create() and TPM2_CreatePrimary(). When a value is indicated as being TPM-generated, the value is filled in by bits from the RNG if the command is TPM2_Create() and with values from **KDFa**() if the command is TPM2_CreatePrimary(). The parameters of each creation value are specified in TPM 2.0 Part 1.

The *sensitiveDataOrigin* attribute of *inPublic* shall be SET if *inSensitive.data* is an Empty Buffer and CLEAR if *inSensitive.data* is not an Empty Buffer or the TPM shall return TPM_RC_ATTRIBUTES.

If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

The TPM will create new data for the sensitive area and compute a TPMT_PUBLIC.*unique* from the sensitive area based on the object type:

a) For a symmetric key:

 Copyright © TCG 2006-2020

1) If *inSensitive*.sensitive.*data* is the Empty Buffer, a TPM-generated key value is placed in the new object's TPMT_SENSITIVE.*sensitive.sym*. The size of the key will be determined by *inPublic.publicArea.parameters*.

2) If *inSensitive*.sensitive.*data* is not the Empty Buffer, the TPM will validate that the size of *inSensitive.data* is no larger than the key size indicated in the *inPublic template* (TPM_RC_SIZE) and copy the *inSensitive.data* to TPMT_SENSITIVE.*sensitive.sym* of the new object.

3) A TPM-generated obfuscation value is placed in TPMT_SENSITIVE.*sensitive.seedValue*. The size of the obfuscation value is the size of the digest produced by the nameAlg in *inPublic*. This value prevents the public *unique* value from leaking information about the *sensitive* area.

4) The TPMT_PUBLIC.*unique.sym* value for the new object is then generated, as shown in equation (1) below, by hashing the key and obfuscation values in the TPMT_SENSITIVE with the *nameAlg* of the object.

$$unique \coloneqq \mathbf{H}_{nameAlg}(sensitive.seedValue.buffer \mid\mid sensitive.any.buffer) \quad (1)$$

b) If the Object is an asymmetric key:

1) If *inSensitive.sensitive.data* is not the Empty Buffer, then the TPM shall return TPM_RC_VALUE.

2) A TPM-generated private key value is created with the size determined by the parameters of inPublic.publicArea.parameters.

3) If the key is a Storage Key, a TPM-generated TPMT_SENSITIVE.*seedValue* value is created; otherwise, TPMT_SENSITIVE.*seedValue.size* is set to zero.

NOTE 3 An Object that is not a storage key has no child Objects to encrypt, so it does not need a symmetric key.

4) The public *unique* value is computed from the private key according to the methods of the key type.

5) If the key is an ECC key and the scheme required by the curveID is not the same as *scheme* in the public area of the template, then the TPM shall return TPM_RC_SCHEME.

6) If the key is an ECC key and the KDF required by the curveID is not the same as *kdf* in the pubic area of the template, then the TPM shall return TPM_RC_KDF.

NOTE 4 There is currently no command in which the caller may specify the KDF to be used with an ECC decryption key. Since there is no use for this capability, the reference implementation requires that the *kdf* in the template be set to TPM_ALG_NULL or TPM_RC_KDF is returned.

c) If the Object is a *keyedHash* object:

1) If *inSensitive.sensitive.data* is an Empty Buffer, and both *sign* and *decrypt* are CLEAR in the attributes of *inPublic*, the TPM shall return TPM_RC_ATTRIBUTES. This would be a data object with no data.

NOTE 5 Revisions 134 and earlier reference code did not check the error case of *sensitiveDataOrigin* SET and an Empty Buffer. Thus, some TPM implementations may also not have included this error check.

2) If *sign* and *decrypt* are both CLEAR, or if *sign* and *decrypt* are both SET and the *scheme* in the public area of the template is not TPM_ALG_NULL, the TPM shall return TPM_RC_SCHEME.

NOTE 6 Revisions 138 and earlier did not enforce this error case.

3) If *inSensitive.sensitive.data* is not an Empty Buffer, the TPM will copy the *inSensitive.sensitive.data* to TPMT_SENSITIVE.*sensitive.bits* of the new object.

NOTE 7 The size of inSensitive.sensitive.data is limited to be no larger than MAX_SYM_DATA.

 Copyright © TCG 2006-2020

4) If *inSensitive.sensitive.data* is an Empty Buffer, a TPM-generated key value that is the size of the digest produced by the *nameAlg* in *inPublic* is placed in TPMT_SENSITIVE.*sensitive.bits*.
5) A TPM-generated obfuscation value that is the size of the digest produced by the *nameAlg* of *inPublic* is placed in TPMT_SENSITIVE.*seedValue*.
6) The TPMT_PUBLIC.*unique.keyedHash* value for the new object is then generated, as shown in equation (1) above, by hashing the key and obfuscation values in the TPMT_SENSITIVE with the *nameAlg* of the object.

For TPM2_Load(), the TPM will apply normal symmetric protections to the created TPMT_SENSITIVE to create *outPublic*.

NOTE 8 The encryption key is derived from the symmetric seed in the sensitive area of the parent.

In addition to *outPublic* and *outPrivate*, the TPM will build a TPMS_CREATION_DATA structure for the object. TPMS_CREATION_DATA.*outsideInfo* is set to *outsideInfo*. This structure is returned in *creationData*. Additionally, the digest of this structure is returned in *creationHash*, and, finally, a TPMT_TK_CREATION is created so that the association between the creation data and the object may be validated by TPM2_CertifyCreation().

If the object being created is a Storage Key and *fixedParent* is SET in the attributes of *inPublic*, then the symmetric algorithms and parameters of *inPublic* are required to match those of the parent. The algorithms that must match are *inPublic.nameAlg*, and the values in *inPublic.parameters* that select the symmetric scheme. If *inPublic.nameAlg* does not match, the TPM shall return TPM_RC_HASH.If the symmetric scheme of the key does not match, the parent, the TPM shall return TPM_RC_SYMMETRIC. The TPM shall not use different response code to differentiate between mismatches of the components of *inPublic.parameters*. However, after this verification, when using the scheme to encrypt child objects, the TPM ignores the symmetric mode and uses TPM_ALG_CFB.

NOTE 9 The symmetric scheme is a TPMT_SYM_DEF_OBJECT. In a symmetric block ciphier, it is at *inPublic.parameters.symDetail.sym* and in an asymmetric object is at *inPublic.parameters.asymDetail.symmetric*.

NOTE 10 Prior to revision 01.34, the parent asymmetric algorithms were also checked for *fixedParent* storage keys.

12.1.3 Detailed Actions

[[Create]]

12.2 TPM2_Load

12.2.1 General Description

This command is used to load objects into the TPM. This command is used when both a TPM2B_PUBLIC and TPM2B_PRIVATE are to be loaded. If only a TPM2B_PUBLIC is to be loaded, the TPM2_LoadExternal command is used.

NOTE 1 Loading an object is not the same as restoring a saved object context.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2 of this specification. If the Object is a not a *keyedHash* object, and the *sign* and *encrypt* attributes are CLEAR, the TPM shall return TPM_RC_ATTRIBUTES.

Objects loaded using this command will have a Name. The Name is the concatenation of *nameAlg* and the digest of the public area using the *nameAlg.*

NOTE 2 *nameAlg* is a parameter in the public area of the inPublic structure.

If *inPrivate.size* is zero, the load will fail.

After *inPrivate.buffer* is decrypted using the symmetric key of the parent, the integrity value shall be checked before the sensitive area is used, or unmarshaled.

NOTE 3 Checking the integrity before the data is used prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the digest of the TPMT_PUBLIC structure in *inPublic*).

NOTE 4 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithms specified in the *nameAlg* of the object.

NOTE 5 The returned handle is associated with the object until the object is flushed (TPM2_FlushContext) or until the next TPM2_Startup.

For all objects, the size of the key in the sensitive area shall be consistent with the key size indicated in the public area or the TPM shall return TPM_RC_KEY_SIZE.

Before use, a loaded object shall be checked to validate that the public and sensitive portions are properly linked, cryptographically. Use of an object includes use in any policy command. If the parts of the object are not properly linked, the TPM shall return TPM_RC_BINDING. If a weak symmetric key is in the sensitive portion, the TPM shall return TPM_RC_KEY.

EXAMPLE 1 For a symmetric object, the unique value in the public area shall be the digest of the sensitive key and the obfuscation value.

EXAMPLE 2 For a two-prime RSA key, the remainder when dividing the public modulus by the private key shall be zero and it shall be possible to form a private exponent from the two prime factors of the public modulus.

EXAMPLE 3 For an ECC key, the public point shall be f(x) where x is the private key.

12.2.3 Detailed Actions

[[Load]]

12.3 TPM2_LoadExternal

12.3.1 General Description

This command is used to load an object that is not a Protected Object into the TPM. The command allows loading of a public area or both a public and sensitive area.

NOTE 1 Typical use for loading a public area is to allow the TPM to validate an asymmetric signature. Typical use for loading both a public and sensitive area is to allow the TPM to be used as a crypto accelerator.

Load of a public external object area allows the object to be associated with a hierarchy so that the correct algorithms may be used when creating tickets. The *hierarchy* parameter provides this association. If the public and sensitive portions of the object are loaded, *hierarchy* is required to be TPM_RH_NULL.

NOTE 2 If both the public and private portions of an object are loaded, the object is not allowed to appear to be part of a hierarchy.

The object's TPMA_OBJECT attributes will be checked according to the rules defined in "TPMA_OBJECT" in TPM 2.0 Part 2. In particular, *fixedTPM*, *fixedParent*, and *restricted* shall be CLEAR if *inPrivate* is not the Empty Buffer.

NOTE 3 The duplication status of a public key needs to be able to be the same as the full key which may be resident on a different TPM. If both the public and private parts of the key are loaded, then it is not possible for the key to be either *fixedTPM* or *fixedParent*, since, its private area would not be available in the clear to load.

Objects loaded using this command will have a Name. The Name is the *nameAlg* of the object concatenated with the digest of the public area using the *nameAlg.* The Qualified Name for the object will be the same as its Name. The TPM will validate that the *authPolicy* is either the size of the digest produced by *nameAlg* or the Empty Buffer.

NOTE 4 If *nameAlg* is TPM_ALG_NULL, then the Name is the Empty Buffer. When the authorization value for an object with no Name is computed, no Name value is included in the HMAC. To ensure that these unnamed entities are not substituted, they should have an *authValue* that is statistically unique.

NOTE 5 The digest size for TPM_ALG_NULL is zero.

If the *nameAlg* is TPM_ALG_NULL, the TPM shall not verify the cryptographic binding between the public and sensitive areas, but the TPM will validate that the size of the key in the sensitive area is consistent with the size indicated in the public area. If it is not, the TPM shall return TPM_RC_KEY_SIZE.

NOTE 6 For an ECC object, the TPM will verify that the public key is on the curve of the key before the public area is used.

If *nameAlg* is not TPM_ALG_NULL, then the same consistency checks between *inPublic* and *inPrivate* are made as for TPM2_Load().

NOTE 7 Consistency checks are necessary because an object with a Name needs to have the public and sensitive portions cryptographically bound so that an attacker cannot mix pubic and sensitive areas.

The command returns a handle for the loaded object and the Name that the TPM computed for *inPublic.public* (that is, the TPMT_PUBLIC structure in *inPublic*).

NOTE 8 The TPM-computed Name is provided as a convenience to the caller for those cases where the caller does not implement the hash algorithm specified in the *nameAlg* of the object.

 Copyright © TCG 2006-2020

The *hierarchy* parameter associates the external object with a hierarchy. External objects are flushed when their associated hierarchy is disabled. If *hierarchy* is TPM_RH_NULL, the object is part of no hierarchy, and there is no implicit flush.

If *hierarchy* is TPM_RH_NULL or *nameAlg* is TPM_ALG_NULL, a ticket produced using the object shall be a NULL Ticket.

EXAMPLE If a key is loaded with hierarchy set to TPM_RH_NULL, then TPM2_VerifySignature() will produce a NULL Ticket of the required type.

External objects are Temporary Objects. The saved external object contexts shall be invalidated at the next TPM Reset.

If a weak symmetric key is in the sensitive area, the TPM shall return TPM_RC_KEY.

For an RSA key, the private exponent is computed using the two prime factors of the public modulus. One of the primes is P, and the second prime (Q) is found by dividing the public modulus by P. A TPM may return an error (TPM_RC_BINDING) if the bit size of P and Q are not the same."

12.3.3 Detailed Actions

[[LoadExternal]]

12.4 TPM2_ReadPublic

12.4.1 General Description

This command allows access to the public area of a loaded object.

Use of the *objectHandle* does not require authorization.

NOTE Since the caller is not likely to know the public area of the object associated with *objectHandle*, it would not be possible to include the Name associated with *objectHandle* in the *cpHash* computation.

If *objectHandle* references a sequence object, the TPM shall return TPM_RC_SEQUENCE.

12.4.3 Detailed Actions

[[ReadPublic]]

12.5 TPM2_ActivateCredential

12.5.1 General Description

This command enables the association of a credential with an object in a way that ensures that the TPM has validated the parameters of the credentialed object.

If both the public and private portions of *activateHandle* and *keyHandle* are not loaded, then the TPM shall return TPM_RC_AUTH_UNAVAILABLE.

If *keyHandle* is not a Storage Key, then the TPM shall return TPM_RC_TYPE.

Authorization for *activateHandle* requires the ADMIN role.

The key associated with *keyHandle* is used to recover a seed from secret, which is the encrypted seed. The Name of the object associated with activateHandle and the recovered seed are used in a KDF to recover the symmetric key. The recovered seed (but not the Name) is used in a KDF to recover the HMAC key.

The HMAC is used to validate that the *credentialBlob* is associated with *activateHandle* and that the data in *credentialBlob* has not been modified. The linkage to the object associated with activateHandle is achieved by including the Name in the HMAC calculation.

If the integrity checks succeed, *credentialBlob* is decrypted and returned as *certInfo*.

NOTE The output *certInfo* parameter is an application defined value. It is typically a symmetric key or seed that is used to decrypt a certificate. See the TPM2_MakeCredential *credential* input parameter.

12.6 TPM2_MakeCredential

12.6.1 General Description

This command allows the TPM to perform the actions required of a Certificate Authority (CA) in creating a TPM2B_ID_OBJECT containing an activation credential.

NOTE The input *credential* parameter is an application defined value. It is typically a symmetric key or seed that is used to encrypt a certificate. See the TPM2_ActivateCredential *certInfo* output parameter.

The TPM will produce a TPM2B_ID_OBJECT according to the methods in "Credential Protection" in TPM 2.0 Part 1.

The loaded public area referenced by *handle* is required to be the public area of a Storage key, otherwise, the credential cannot be properly sealed.

This command does not use any TPM secrets nor does it require authorization. It is a convenience function, using the TPM to perform cryptographic calculations that could be done externally.

[[MakeCredential]]

12.7 TPM2_Unseal

12.7.1 General Description

This command returns the data in a loaded Sealed Data Object.

NOTE 1 A random, TPM-generated, Sealed Data Object may be created by the TPM with TPM2_Create() or TPM2_CreatePrimary() using the template for a Sealed Data Object.

NOTE 2 TPM 1.2 hard coded PCR authorization. TPM 2.0 PCR authorization requires a policy.

The returned value may be encrypted using authorization session encryption.

If either *restricted*, *decrypt,* or *sign* is SET in the attributes of *itemHandle,* then the TPM shall return TPM_RC_ATTRIBUTES. If the *type* of *itemHandle* is not TPM_ALG_KEYEDHASH, then the TPM shall return TPM_RC_TYPE.

12.8 TPM2_ObjectChangeAuth

12.8.1 General Description

This command is used to change the authorization secret for a TPM-resident object.

If successful, a new private area for the TPM-resident object associated with *objectHandle* is returned, which includes the new authorization value.

This command does not change the authorization of the TPM-resident object on which it operates. Therefore, the old authValue (of the TPM-resident object) is used when generating the response HMAC key if required.

NOTE 1 The returned *outPrivate* will need to be loaded before the new authorization will apply.

NOTE 2 The TPM-resident object may be persistent and changing the authorization value of the persistent object could prevent other users from accessing the object. This is why this command does not change the TPM-resident object.

EXAMPLE If a persistent key is being used as a Storage Root Key and the authorization of the key is a well-known value so that the key can be used generally, then changing the authorization value in the persistent key would deny access to other users.

This command may not be used to change the authorization value for an NV Index or a Primary Object.

NOTE 3 If an NV Index is to have a new authorization, it is done with TPM2_NV_ChangeAuth().

NOTE 4 If a Primary Object is to have a new authorization, it needs to be recreated (TPM2_CreatePrimary()).

12.8.3 Detailed Actions

[[ObjectChangeAuth]]

12.9 TPM2_CreateLoaded

12.9.1 General Description

This command creates an object and loads it in the TPM. This command allows creation of any type of object (Primary, Ordinary, or Derived) depending on the type of *parentHandle.* If *parentHandle* references a Primary Seed, then a Primary Object is created; if *parentHandle* references a Storage Parent, then an Ordinary Object is created; and if *parentHandle* references a Derivation Parent, then a Derived Object is generated.

The input validation is the same as for TPM2_Create() and TPM2_CreatePrimary() with one exception: when *parentHandle* references a Derivation Parent, then *sensitiveDataOrigin* in *inPublic* is required to be CLEAR.

Note 1 In the general descriptions of TPM2_Create() and TPM2_CreatePrimary() the validations refer to a TPMT_PUBLIC structure that is in *inPublic.* For TPM2_CreateLoaded(), *inPublic* is a TPM2B_TEMPLATE that may contain a TPMT_PUBLIC that is used for object creation. For object derivation, the *unique* field can contain a *label* and *context* that are used in the derivation process. To allow both the TPMT_PUBLIC and the derivation variation, a TPM2B_TEMPLATE is used. When referring to the checks in TPM2_Create() and TPM2_CreatePrimary(), TPM2B_TEMPLATE should be assumed to contain a TPMT_PUBLIC.

If *parentHandle* references a Derivation Parent, then the TPM may return TPM_RC_TYPE if the key type to be generated is an RSA key.

If *parentHandle* references a Derivation Parent or a Primary Seed, then *outPrivate* will be an Empty Buffer.

NOTE 2 Returning outPrivate would imply that the returned primary or derived object can be loaded and it cannot. It can only be re-derived.

A primary key cannot be loaded is because loading a key is a way to attack the protections of a key (e.g. using DPA). A saved context for a primary object is protected. The TPM will go into failure mode if the integrity of a saved context is good but the fingerprint doesn't decrypt. It is not possible to have these protections on loaded objects because this would be a simple way for an attacker to put the TPM into failure mode Saved contexts are assumed to be under control of the driver but loaded objects are not.

If all objects were derived from their parents then, load could not be used as an attack. However, that would preclude importation of objects and key hierarchies.

NOTE 3 Unlike TPM2_Create() and TPM2_CreatePrimary(), this command does not return creation data. If creation data is needed, then TPM2_Create() or TPM2_CreatePrimary() should be used.

13 Duplication Commands

13.1 TPM2_Duplicate

13.1.1 General Description

This command duplicates a loaded object so that it may be used in a different hierarchy. The new parent key for the duplicate may be on the same or different TPM or TPM_RH_NULL. Only the public area of *newParentHandle* is required to be loaded.

NOTE 1 Since the new parent may only be extant on a different TPM, it is likely that the new parent's sensitive area could not be loaded in the TPM from which *objectHandle* is being duplicated.

If *encryptedDuplication* is SET in the object being duplicated, then the TPM shall return TPM_RC_SYMMETRIC if *symmetricAlg.algorithm* is TPM_ALG_NULL or TPM_RC_HIERARCHY if *newParentHandle* is TPM_RH_NULL.

The authorization for this command shall be with a policy session.

If *fixedParent* of *objectHandle→attributes* is SET, the TPM shall return TPM_RC_ATTRIBUTES. If *objectHandle→nameAlg* is TPM_ALG_NULL, the TPM shall return TPM_RC_TYPE.

The *policySession→commandCode* parameter in the policy session is required to be TPM_CC_Duplicate to indicate that authorization for duplication has been provided. This indicates that the policy that is being used is a policy that is for duplication, and not a policy that would approve another use. That is, authority to use an object does not grant authority to duplicate the object.

The policy is likely to include cpHash in order to restrict where duplication can occur. If TPM2_PolicyCpHash() has been executed as part of the policy, the *policySession→cpHash* is compared to the cpHash of the command.

If TPM2_PolicyDuplicationSelect() has been executed as part of the policy, the *policySession→nameHash* is compared to

$$\mathbf{H}_{policyAlg}(objectHandle{\rightarrow}Name \mid\mid newParentHandle{\rightarrow}Name) \quad (2)$$

If the compared hashes are not the same, then the TPM shall return TPM_RC_POLICY_FAIL.

NOTE 2 It is allowed that policySesion→nameHash and policySession→cpHash share the same memory space.

NOTE 3 A duplication policy is not required to have either TPM2_PolicyDuplicationSelect() or TPM2_PolicyCpHash() as part of the policy. If neither is present, then the duplication policy may be satisfied with a policy that only contains TPM2_PolicyCommandCode(*code* = TPM_CC_Duplicate).

The TPM shall follow the process of encryption defined in the "Duplication" subclause of "Protected Storage Hierarchy" in TPM 2.0 Part 1.

 Copyright © TCG 2006-2020

13.1.3 Detailed Actions

[[Duplicate]]

13.2 TPM2_Rewrap

13.2.1 General Description

This command allows the TPM to serve in the role as a Duplication Authority. If proper authorization for use of the *oldParent* is provided, then an HMAC key and a symmetric key are recovered from *inSymSeed* and used to integrity check and decrypt *inDuplicate.* A new protection seed value is generated according to the methods appropriate for *newParent* and the blob is re-encrypted and a new integrity value is computed. The re-encrypted blob is returned in *outDuplicate* and the symmetric key returned in *outSymKey*.

In the rewrap process, L is "DUPLICATE" (see TPM 2.0 Part 1, *Terms and Definitions*).

If *inSymSeed* has a zero length, then *oldParent* is required to be TPM_RH_NULL and no decryption of *inDuplicate* takes place.

If *newParent* is TPM_RH_NULL, then no encryption is performed on *outDuplicate. outSymSeed* will have a zero length. See TPM 2.0 Part 2 *encryptedDuplication*.

13.3 TPM2_Import

13.3.1 General Description

This command allows an object to be encrypted using the symmetric encryption values of a Storage Key. After encryption, the object may be loaded and used in the new hierarchy. The imported object (*duplicate*) may be singly encrypted, multiply encrypted, or unencrypted.

If *fixedTPM* or *fixedParent* is SET in *objectPublic*, the TPM shall return TPM_RC_ATTRIBUTES.

If *encryptedDuplication* is SET in the object referenced by *parentHandle* and *encryptedDuplication* is CLEAR in *objectPublic,* the TPM may return TPM_RC_ATTRIBUTES.

If encryptedDuplication is SET in objectPublic, then *inSymSeed* and *encryptionKey* shall not be Empty buffers (TPM_RC_ATTRIBUTES). Recovery of the sensitive data of the object occurs in the TPM in a multi--step process in the following order:

a) If *inSymSeed* has a non-zero size:

1) The asymmetric parameters and private key of *parentHandle* are used to recover the seed used in the creation of the HMAC key and encryption keys used to protect the duplication blob.

NOTE 1 When recovering the seed from *inSymSeed*, *L* is "DUPLICATE".

2) The integrity value in *duplicate.buffer.integrityOuter* is used to verify the integrity of the data blob, which is the remainder of *duplicate.buffer* (TPM_RC_INTEGRITY).

NOTE 2 The data blob will contain a TPMT_SENSITIVE and may contain a TPM2B_DIGEST for the *innerIntegrity.*

3) The symmetric key recovered in 1) is used to decrypt the data blob.

NOTE 3 Checking the integrity before the data is used prevents attacks on the sensitive area by fuzzing the data and looking at the differences in the response codes.

b) If *encryptionKey* is not an Empty Buffer:

1) Use *encryptionKey* to decrypt the inner blob.

2) Use the TPM2B_DIGEST at the start of the inner blob to verify the integrity of the inner blob (TPM_RC_INTEGRITY).

c) Unmarshal the sensitive area

NOTE 4 It is not necessary to validate that the sensitive area data is cryptographically bound to the public area other than that the Name of the public area is included in the HMAC. However, if the binding is not validated by this command, the binding must be checked each time the object is loaded. For an object that is imported under a parent with *fixedTPM* SET, binding need only be checked at import. If the parent has *fixedTPM* CLEAR, then the binding needs to be checked each time the object is loaded, or before the TPM performs an operation for which the binding affects the outcome of the operation (for example, TPM2_PolicySigned() or TPM2_Certify()).

Similarly, if the new parent's *fixedTPM* is set, the *encryptedDuplication* state need only be checked at import.

If the new parent is not *fixedTPM*, then that object will be loadable on any TPM (including SW versions) on which the new parent exists. This means that, each time an object is loaded under a parent that is not *fixedTPM*, it is necessary to validate all of the properties of that object. If the parent is *fixedTPM*, then the new private blob is integrity protected by the TPM that "owns" the parent. So, it is sufficient to validate the object's properties (attribute and public-private binding) on import and not again.

If a weak symmetric key is being imported, the TPM shall return TPM_RC_KEY.

After integrity checks and decryption, the TPM will create a new symmetrically encrypted private area using the encryption key of the parent.

NOTE 5 The symmetric re-encryption is the normal integrity generation and symmetric encryption applied to a child object.

NOTE 6 Revision 01.16 of this specification required the ECC private key in *duplicate* to be padded.

13.3.3 Detailed Actions

[[Import]]

14 Asymmetric Primitives

14.1 Introduction

The commands in this clause provide low-level primitives for access to the asymmetric algorithms implemented in the TPM. Many of these commands are only allowed if the asymmetric key is an unrestricted key.

14.2 TPM2_RSA_Encrypt

14.2.1 General Description

This command performs RSA encryption using the indicated padding scheme according to IETF RFC 8017. If the *scheme* of *keyHandle* is TPM_ALG_NULL, then the caller may use *inScheme* to specify the padding scheme. If *scheme* of keyHandle is not TPM_ALG_NULL, then *inScheme* shall either be TPM_ALG_NULL or be the same as *scheme* (TPM_RC_SCHEME).

The key referenced by *keyHandle* is required to be an RSA key (TPM_RC_KEY).

The three types of allowed padding are:

1) TPM_ALG_OAEP – Data is OAEP padded as described in 7.1 of IETF RFC 8017 (PKCS#1). The only supported mask generation is MGF1.

2) TPM_ALG_RSAES – Data is padded as described in 7.2 of IETF RFC 8017 (PKCS#1).

3) TPM_ALG_NULL – Data is not padded by the TPM and the TPM will treat *message* as an unsigned integer and perform a modular exponentiation of *message* using the public exponent of the key referenced by *keyHandle*. This scheme is only used if both the *scheme* in the key referenced by *keyHandle* is TPM_ALG_NULL, and the *inScheme* parameter of the command is TPM_ALG_NULL. The input value cannot be larger than the public modulus of the key referenced by *keyHandle*.

Table 43 — Padding Scheme Selection

<table>
<tr><th>keyHandle→scheme</th><th>inScheme</th><th>padding scheme used</th></tr>
<tr><td rowspan="3">TPM_ALG_NULL</td><td>TPM_ALG_NULL</td><td>none</td></tr>
<tr><td>TPM_ALG_RSAES</td><td>RSAES</td></tr>
<tr><td>TPM_ALG_OAEP</td><td>OAEP</td></tr>
<tr><td rowspan="3">TPM_ALG_RSAES</td><td>TPM_ALG_NULL</td><td>RSAES</td></tr>
<tr><td>TPM_ALG_RSAES</td><td>RSAES</td></tr>
<tr><td>TPM_ALG_OAEP</td><td>error (TPM_RC_SCHEME)</td></tr>
<tr><td rowspan="3">TPM_ALG_OAEP</td><td>TPM_ALG_NULL</td><td>OAEP</td></tr>
<tr><td>TPM_ALG_RSAES</td><td>error (TPM_RC_SCHEME)</td></tr>
<tr><td>TPM_ALG_OAEP</td><td>OAEP</td></tr>
</table>

After padding, the data is RSAEP encrypted according to 5.1.1 of IETF RFC 8017 (PKCS#1).

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

NOTE 1 Because only the public portion of the key needs to be loaded for this command, the caller can manipulate the attributes of the key in any way desired. As a result, the TPM shall not check the consistency of the attributes. The only property checking is that the key is an RSA key and that the padding scheme is supported.

The *message* parameter is limited in size by the padding scheme according to the following table:

Table 44 — Message Size Limits Based on Padding

Scheme	Maximum Message Length (*mLen*) in Octets	Comments
TPM_ALG_OAEP	$mLen \leq k - 2hLen - 2$	
TPM_ALG_RSAES	$mLen \leq k - 11$	
TPM_ALG_NULL	$mLen \leq k$	The numeric value of the message must be less than the numeric value of the public modulus (n).
NOTES 1) k ≔ the number of byes in the public modulus 2) $hLen$ ≔ the number of octets in the digest produced by the hash algorithm used in the process		

The *label* parameter is optional. If provided (*label.size* != 0) then the TPM shall return TPM_RC_VALUE if the last octet in *label* is not zero. The terminating octet of zero is included in the *label* used in the padding scheme.

NOTE 2 If the scheme does not use a label, the TPM will still verify that label is properly formatted if label is present.

NOTE 3 Specifications before version 1.54 stated that *label* is truncated after the first zero octet. Applications should not include embedded zero bytes for compatibility.

The function returns padded and encrypted value *outData*.

The *message* parameter in the command may be encrypted using parameter encryption.

NOTE 4 Only the public area of *keyHandle* is required to be loaded. A public key may be loaded with any desired scheme. If the scheme is to be changed, a different public area must be loaded.

14.3 TPM2_RSA_Decrypt

14.3.1 General Description

This command performs RSA decryption using the indicated padding scheme according to IETF RFC 8017 ((PKCS#1).

The scheme selection for this command is the same as for TPM2_RSA_Encrypt() and is shown in Table 43.

The key referenced by *keyHandle* shall be an RSA key (TPM_RC_KEY) with *restricted* CLEAR and *decrypt* SET (TPM_RC_ATTRIBUTES).

This command uses the private key of *keyHandle* for this operation and authorization is required.

The TPM will perform a modular exponentiation of ciphertext using the private exponent associated with *keyHandle* (this is described in IETF RFC 8017 (PKCS#1), clause 5.1.2). It will then validate the padding according to the selected scheme. If the padding checks fail, TPM_RC_VALUE is returned. Otherwise, the data is returned with the padding removed. If no padding is used, the returned value is an unsigned integer value that is the result of the modular exponentiation of *cipherText* using the private exponent of *keyHandle*. The returned value may include leading octets zeros so that it is the same size as the public modulus. For the other padding schemes, the returned value will be smaller than the public modulus but will contain all the data remaining after padding is removed and this may include leading zeros if the original encrypted value contained leading zeros.

If a label is used in the padding process of the scheme during encryption, the *label* parameter is required to be present in the decryption process and *label* is required to be the same in both cases. If label is not the same, the decrypt operation is very likely to fail ((TPM_RC_VALUE). If *label* is present (*label.size* != 0), it shall be a byte stream whose last byte is zero or the TPM will return TPM_RC_VALUE.

NOTE 1 The size of *label* includes the terminating null.

The *message* parameter in the response may be encrypted using parameter encryption.

If *inScheme* is used, and the scheme requires a hash algorithm it may not be TPM_ALG_NULL.

If the scheme does not require a label, the value in *label* is not used but the size of the label field is checked for consistency with the indicated data type (TPM2B_DATA). That is, the field may not be larger than allowed for a TPM2B_DATA.

14.4 TPM2_ECDH_KeyGen

14.4.1 General Description

This command uses the TPM to generate an ephemeral key pair (d_e, Q_e where $Q_e \coloneqq [d_e]G$). It uses the private ephemeral key and a loaded public key (Q_S) to compute the shared secret value ($P \coloneqq [hd_e]Q_S$).

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY). The sensitive portion of this key need not be loaded.

The curve parameters of the loaded ECC key are used to generate the ephemeral key.

NOTE This function is the equivalent of encrypting data to another object's public key. The *seed* value is used in a KDF to generate a symmetric key and that key is used to encrypt the data. Once the data is encrypted and the symmetric key discarded, only the object with the private portion of the *keyHandle* will be able to decrypt it.

The *zPoint* in the response may be encrypted using parameter encryption.

14.4.3 Detailed Actions

[[ECDH_KeyGen]]

14.5 TPM2_ECDH_ZGen

14.5.1 General Description

This command uses the TPM to recover the *Z* value from a public point (Q_B) and a private key (d_s). It will perform the multiplication of the provided *inPoint* (Q_B) with the private key (d_s) and return the coordinates of the resultant point ($Z = (x_Z, y_Z) \coloneqq [hd_s]Q_B$; where h is the cofactor of the curve).

keyHandle shall refer to a loaded, ECC key (TPM_RC_KEY) with the *restricted* attribute CLEAR and the *decrypt* attribute SET (TPM_RC_ATTRIBUTES).

NOTE While TPM_RC_ATTRIBUTES is preferred, TPM_RC_KEY is acceptable.

The *scheme* of the key referenced by *keyHandle* is required to be either TPM_ALG_ECDH or TPM_ALG_NULL (TPM_RC_SCHEME).

inPoint is required to be on the curve of the key referenced by *keyHandle* (TPM_RC_ECC_POINT).

The parameters of the key referenced by *keyHandle* are used to perform the point multiplication.

14.6 TPM2_ECC_Parameters

14.6.1 General Description

This command returns the parameters of an ECC curve identified by its TCG-assigned *curveID*.

The value returned is the same as that from the TCG Algorithm Registry, but may not be the same size.

EXAMPLE The value 01 may be returned as 00000001.

14.7 TPM2_ZGen_2Phase

14.7.1 General Description

This command supports two-phase key exchange protocols. The command is used in combination with TPM2_EC_Ephemeral(). TPM2_EC_Ephemeral() generates an ephemeral key and returns the public point of that ephemeral key along with a numeric value that allows the TPM to regenerate the associated private key.

The input parameters for this command are a static public key (*inQsU*), an ephemeral key (*inQeU*) from party B, and the *commitCounter* returned by TPM2_EC_Ephemeral(). The TPM uses the counter value to regenerate the ephemeral private key ($d_{e,V}$) and the associated public key ($Q_{e,V}$). *keyA* provides the static ephemeral elements $d_{s,V}$ and $Q_{s,V}$. This provides the two pairs of ephemeral and static keys that are required for the schemes supported by this command.

The TPM will compute $Z\ or\ Z_s$ and Z_e according to the selected scheme. If the scheme is not a two-phase key exchange scheme or if the scheme is not supported, the TPM will return TPM_RC_SCHEME.

It is an error if *inQsB* or *inQeB* are not on the curve of *keyA* (TPM_RC_ECC_POINT).

The two-phase key schemes that were assigned an algorithm ID as of the time of the publication of this specification are TPM_ALG_ECDH, TPM_ALG_ECMQV, and TPM_ALG_SM2.

If this command is supported, then support for TPM_ALG_ECDH is required. Support for TPM_ALG_ECMQV or TPM_ALG_SM2 is optional.

NOTE 1 If SM2 is supported and this command is supported, then the implementation is required to support the key exchange protocol of SM2, part 3.

For TPM_ALG_ECDH *outZ1* will be Zs and *outZ2* will Ze as defined in 6.1.1.2 of SP800-56A.

NOTE 2 An unrestricted decryption key using ECDH may be used in either TPM2_ECDH_ZGen() or TPM2_ZGen_2Phase as the computation done with the private part of *keyA* is the same in both cases.

For TPM_ALG_ECMQV or TPM_ALG_SM2 *outZ1* will be Z and *outZ2* will be an Empty Point.

NOTE 3 An Empty Point has two Empty Buffers as coordinates meaning the minimum *size* value for *outZ2* will be four.

If the input scheme is TPM_ALG_ECDH, then *outZ1* will be Z_s and outZ2 will be Z_e. For schemes like MQV (including SM2), *outZ1* will contain the computed value and *outZ2* will be an Empty Point.

NOTE 4 The Z values returned by the TPM are a full point and not just an x-coordinate.

If a computation of either Z produces the point at infinity, then the corresponding Z value will be an Empty Point.

14.7.3 Detailed Actions

[[ZGen_2Phase]]

15 Symmetric Primitives

15.1 Introduction

The commands in this clause provide low-level primitives for access to the symmetric algorithms implemented in the TPM that operate on blocks of data. These include symmetric encryption and decryption as well as hash and HMAC. All of the commands in this group are stateless. That is, they have no persistent state that is retained in the TPM when the command is complete.

For hashing, HMAC, and Events that require large blocks of data with retained state, the sequence commands are provided (see clause 17).

Some of the symmetric encryption/decryption modes use an IV. When an IV is used, it may be an initiation value or a chained value from a previous stage. The chaining for each mode is:

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

Table 57 — Symmetric Chaining Process

Mode	Chaining process
TPM_ALG_CTR	The TPM will increment the entire IV provided by the caller. The next count value will be returned to the caller as *ivOut*. This can be the input value to the next encrypt or decrypt operation. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. EXAMPLE 1 AES requires that *ivIn* be 128 bits (16 octets). *ivOut* will be the size of a cipher block and not the size of the last encrypted block. NOTE *ivOut* will be the value of the counter after the last block is encrypted. EXAMPLE 2 If *ivIn* were 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00_{16} and four data blocks were encrypted, *ivOut* will have a value of 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 04_{16}. All the bits of the IV are incremented as if it were an unsigned integer.
TPM_ALG_OFB	In Output Feedback (OFB), the output of the pseudo-random function (the block encryption algorithm) is XORed with a plaintext block to produce a ciphertext block. *ivOut* will be the value that was XORed with the last plaintext block. That value can be used as the *ivIn* for a next buffer. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *ivOut* will be the size of a cipher block and not the size of the last encrypted block.
TPM_ALG_CBC	For Cipher Block Chaining (CBC), a block of ciphertext is XORed with the next plaintext block and that block is encrypted. The encrypted block is then input to the encryption of the next block. The last ciphertext block then is used as an IV for the next buffer. Even though the last ciphertext block is evident in the encrypted data, it is also returned in *ivOut*. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *inData* is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of *inData* is not correct, the TPM shall return TPM_RC_SIZE.
TPM_ALG_CFB	Similar to CBC in that the last ciphertext block is an input to the encryption of the next block. *ivOut* will be the value that was XORed with the last plaintext block. That value can be used as the *ivIn* for a next buffer. *ivIn* is required to be the size of a block encrypted by the selected algorithm and key combination. If the size of *ivIn* is not correct, the TPM shall return TPM_RC_SIZE. *ivOut* will be the size of a cipher block and not the size of the last encrypted block.
TPM_ALG_ECB	Electronic Codebook (ECB) has no chaining. Each block of plaintext is encrypted using the key. ECB does not support chaining and *ivIn* shall be the Empty Buffer. *ivOut* will be the Empty Buffer. *inData* is required to be an even multiple of the block encrypted by the selected algorithm and key combination. If the size of *inData* is not correct, the TPM shall return TPM_RC_SIZE.

15.2 TPM2_EncryptDecrypt

15.2.1 General Description

NOTE 1 This command is deprecated, and TPM2_EncryptDecrypt2() is preferred. This should be reflected in platform-specific specifications.

This command performs symmetric encryption or decryption using the symmetric key referenced by keyHandle and the selected mode.

keyHandle shall reference a symmetric cipher object (TPM_RC_KEY) with the *restricted* attribute CLEAR (TPM_RC_ATTRIBUTES).

If the *decrypt* parameter of the command is TRUE, then the *decrypt* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES). If the *decrypt* parameter of the command is FALSE, then the *sign* attribute of the key is required to be SET (TPM_RC_ATTRIBUTES).

NOTE 2 A key may have both *decrypt* and *sign* SET.

If the mode of the key is not TPM_ALG_NULL, then that is the only mode that can be used with the key and the caller is required to set *mode* either to TPM_ALG_NULL or to the same mode as the key (TPM_RC_MODE). If the mode of the key is TPM_ALG_NULL, then the caller may set *mode* to any valid symmetric encryption/decryption mode but may not select TPM_ALG_NULL (TPM_RC_MODE).

If the TPM allows this command to be canceled before completion, then the TPM may produce incremental results and return TPM_RC_SUCCESS rather than TPM_RC_CANCELED. In such case, *outData* may be less than *inData*.

NOTE 3 If all the data is encrypted/decrypted, the size of outData will be the same as inData.

[[EncryptDecrypt2]]

15.4 TPM2_Hash

15.4.1 General Description

This command performs a hash operation on a data buffer and returns the results.

NOTE If the data buffer to be hashed is larger than will fit into the TPM's input buffer, then the sequence hash commands will need to be used.

If the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign.

If the digest is not safe to sign, then the TPM will return a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

15.5 TPM2_HMAC

15.5.1 General Description

This command performs an HMAC on the supplied data using the indicated hash algorithm.

NOTE 1 A TPM may implement either TPM2_HMAC() or TPM2_MAC() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC(), but a TPM that supports TPM2_HMAC() will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then hashAlg is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see hash selection matrix in

Table 72).

NOTE 3 A key may only have both sign and decrypt SET if the key is unrestricted. When both sign and decrypt are set, there is no default scheme for the key and the hash algorithm must be specified.

[[HMAC]]

15.6 TPM2_MAC

15.6.1 General Description

This command performs an HMAC or a block cipher MAC on the supplied data using the indicated algorithm.

NOTE 1 A TPM may implement either TPM2_HMAC() or TPM2_MAC() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC() will support any code that was written to use TPM2_HMAC() but a TPM that supports TPM2_HMAC () will not support a MAC based on symmetric block ciphers.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is neither TPM_ALG_KEYEDHASH nor TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme or mode of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE).

If the default scheme of an HMAC key is TPM_ALG_NULL, then *inScheme* is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE) (see algorithm selection matrix in

Table 75).

If the default mode of a symmetric cipher key is TPM_ALG_NULL, then *inScheme* is required to be a valid block cipher mode for authentication and not TPM_ALG_NULL (TPM_RC_VALUE)

NOTE 3 A key may only have both sign and decrypt SET if the key is unrestricted. When both sign and decrypt are set, there is no default scheme for the key and *inScheme* may not be TPM_ALG_NULL.

NOTE 4 TPM2_MAC() was added in revision 01.43.

16 Random Number Generator

16.1 TPM2_GetRandom

16.1.1 General Description

This command returns the next *bytesRequested* octets from the random number generator (RNG).

NOTE 1 It is recommended that a TPM implement the RNG in a manner that would allow it to return RNG octets such that, as long as the value of *bytesRequested* is not greater than the maximum digest size, the frequency of *bytesRequested* being more than the number of octets available is an infrequent occurrence.

If *bytesRequested* is more than will fit into a TPM2B_DIGEST on the TPM, no error is returned but the TPM will only return as much data as will fit into a TPM2B_DIGEST buffer for the TPM.

NOTE 2 TPM2B_DIGEST is large enough to hold the largest digest that may be produced by the TPM. Because that digest size changes according to the implemented hashes, the maximum amount of data returned by this command is TPM implementation-dependent.

17 Hash/HMAC/Event Sequences

17.1 Introduction

All of the commands in this group are to support sequences for which an intermediate state must be maintained. For a description of sequences, see “Hash, MAC, and Event Sequences” in TPM 2.0 Part 1.

A TPM may implement either TPM2_HMAC_Start() or TPM2_MAC_Start() but not both as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC_Start() but a TPM that supports TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

17.2 TPM2_HMAC_Start

17.2.1 General Description

This command starts an HMAC sequence. The TPM will create and initialize an HMAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *hashAlg* parameter is required to be either the same as the key’s default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then hashAlg is required to be a valid hash and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 72 — Hash Selection Matrix

handle→restricted **(key's restricted attribute)**	***handle→scheme*** **(hash algorithm from key's *scheme*)**	***hashAlg***	**hash used**
CLEAR (unrestricted)	TPM_ALG_NULL[(1)]	TPM_ALG_NULL	error[(1)] (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash	*hashAlg*
CLEAR	valid hash	TPM_ALG_NULL or same as *handle→scheme*	*handle→scheme*
CLEAR	valid hash	valid hash	error (TPM_RC_VALUE) if *hashAlg* != *handle->scheme*
SET (restricted)	don't care	don't care	TPM_RC_ATTRIBUTES
NOTES: 1) A hash algorithm is required for the HMAC.			

NOTE 1 A TPM may implement either TPM2_HMAC_Start() or TPM2_MAC_Start() but not both, as they have the same command code and there is no way to distinguish them. A TPM that supports TPM2_MAC_Start() will support any code that was written to use TPM2_HMAC_Start(), but a TPM that supports TPM2_HMAC_Start() will not support a MAC based on symmetric block ciphers.

[[HMAC_Start]]

17.3 TPM2_MAC_Start

17.3.1 General Description

This command starts a MAC sequence. The TPM will create and initialize a MAC sequence structure, assign a handle to the sequence, and set the *authValue* of the sequence object to the value in *auth*.

NOTE 1 The structure of a sequence object is vendor-dependent.

The caller shall provide proper authorization for use of *handle*.

If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY. If the key type is not TPM_ALG_KEYEDHASH or TPM_ALG_SYMCIPHER then the TPM shall return TPM_RC_TYPE. If the key referenced by *handle* has the *restricted* attribute SET, the TPM shall return TPM_RC_ATTRIBUTES.

NOTE 2 For symmetric signing with a restricted key, see TPM2_Sign.

If the default scheme of the key referenced by *handle* is not TPM_ALG_NULL, then the *inScheme* parameter is required to be either the same as the key's default or TPM_ALG_NULL (TPM_RC_VALUE). If the default scheme of the key is TPM_ALG_NULL, then *inScheme*is required to be a valid hash or symmetric MAC scheme and not TPM_ALG_NULL (TPM_RC_VALUE).

Table 75 — Algorithm Selection Matrix

handle→restricted **(key's restricted attribute)**	***handle→scheme*** **(algorithm from key's *scheme*)**	***inScheme***	**algorithm used**
CLEAR (unrestricted)	TPM_ALG_NULL(1)	TPM_ALG_NULL	error(1) (TPM_RC_VALUE)
CLEAR	TPM_ALG_NULL	valid hash or symmetric MAC	*inScheme*
CLEAR	not TPM_ALG_NULL	TPM_ALG_NULL or same as *handle→scheme*	*handle→scheme*
CLEAR	not TPM_ALG_NULL	not TPM_AGL_NULL	error (TPM_RC_VALUE) if*inScheme*!= *handle->scheme*
SET (restricted)	don't care	don't care	TPM_RC_ATTRIBUTES
NOTES: 1) A hash algorithm is required for the HMAC. 2) hashAlg shall be TPM_ALG_NULL for handle referencing a CMAC key.			

NOTE 3 For a TPM_ALG_SYMCIPHER key, the symmetric block cipher algorithm is part of the key definition.

NOTE 4 TPM2_MAC_Start() was added in revision 01.43.

[[MAC_Start]]

17.4 TPM2_HashSequenceStart

17.4.1 General Description

This command starts a hash or an Event Sequence. If *hashAlg* is an implemented hash, then a hash sequence is started. If *hashAlg* is TPM_ALG_NULL, then an Event Sequence is started. If *hashAlg* is neither an implemented algorithm nor TPM_ALG_NULL, then the TPM shall return TPM_RC_HASH.

Depending on *hashAlg*, the TPM will create and initialize a Hash Sequence context or an Event Sequence context. Additionally, it will assign a handle to the context and set the *authValue* of the context to the value in *auth*. A sequence context for an Event (*hashAlg* = TPM_ALG_NULL) contains a hash context for each of the PCR banks implemented on the TPM.

17.5 TPM2_SequenceUpdate

17.5.1 General Description

This command is used to add data to a hash or HMAC sequence. The amount of data in buffer may be any size up to the limits of the TPM.

NOTE 1 In all TPM, a *buffer* size of 1,024 octets is allowed.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If the command does not return TPM_RC_SUCCESS, the state of the sequence is unmodified.

If the sequence is intended to produce a digest that will be signed by a restricted signing key, then the first block of data shall contain sizeof(TPM_GENERATED) octets and the first octets shall not be TPM_GENERATED_VALUE.

NOTE 2 This requirement allows the TPM to validate that the first block is safe to sign without having to accumulate octets over multiple calls.

17.6 TPM2_SequenceComplete

17.6.1 General Description

This command adds the last part of data, if any, to a hash/HMAC sequence and returns the result.

NOTE 1 This command is not used to complete an Event Sequence. TPM2_EventSequenceComplete() is used for that purpose.

For a hash sequence, if the results of the hash will be used in a signing operation that uses a restricted signing key, then the ticket returned by this command can indicate that the hash is safe to sign.

If the *digest* is not safe to sign, then *validation* will be a TPMT_TK_HASHCHECK with the hierarchy set to TPM_RH_NULL and *digest* set to the Empty Buffer.

If *hierarchy* is TPM_RH_NULL, then *digest* in the ticket will be the Empty Buffer.

NOTE 2 Regardless of the contents of the first octets of the hashed message, if the first buffer sent to the TPM had fewer than sizeof(TPM_GENERATED) octets, then the TPM will operate as if *digest* is not safe to sign.

NOTE 3 The ticket is only required for a signing operation that uses a restricted signing key. It is always returned, but can be ignored if not needed.

If *sequenceHandle* references an Event Sequence, then the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

[[SequenceComplete]]

17.7 TPM2_EventSequenceComplete

17.7.1 General Description

This command adds the last part of data, if any, to an Event Sequence and returns the result in a digest list. If *pcrHandle* references a PCR and not TPM_RH_NULL, then the returned digest list is processed in the same manner as the digest list input parameter to TPM2_PCR_Extend(). That is, if a bank contains a PCR associated with *pcrHandle,* it is extended with the associated digest value from the list.

If *sequenceHandle* references a hash or HMAC sequence, the TPM shall return TPM_RC_MODE.

Proper authorization for the sequence object associated with *sequenceHandle* is required. If an authorization or audit of this command requires computation of a *cpHash* and an *rpHash*, the Name associated with *sequenceHandle* will be the Empty Buffer.

If this command completes successfully, the *sequenceHandle* object will be flushed.

NOTE: Unlike TPM2_PCR_Event(), a digest is always returned for each implemented hash algorithm. There is no option to only return digests for which *pcrHandle* is allocated.

18 Attestation Commands

18.1 Introduction

The attestation commands cause the TPM to sign an internally generated data structure. The contents of the data structure vary according to the command.

If the *sign* attribute is not SET in the key referenced by *signHandle* then the TPM shall return TPM_RC_KEY.

All signing commands include a parameter (typically *inScheme*) for the caller to specify a scheme to be used for the signing operation. This scheme will be applied only if the scheme of the key is TPM_ALG_NULL or the key handle is TPM_RH_NULL. If the scheme for *signHandle* is not TPM_ALG_NULL, then *inScheme.scheme* shall be TPM_ALG_NULL or the same as *scheme* in the public area of the key. If the scheme for *signHandle* is TPM_ALG_NULL or the key handle is TPM_RH_NULL, then *inScheme* will be used for the signing operation and may not be TPM_ALG_NULL. The TPM shall return TPM_RC_SCHEME to indicate that the scheme is not appropriate.

For a signing key that is not restricted, the caller may specify the scheme to be used as long as the scheme is compatible with the family of the key (for example, TPM_ALG_RSAPSS cannot be selected for an ECC key). If the caller sets *scheme* to TPM_ALG_NULL, then the default scheme of the key is used. For a restricted signing key, the key's scheme cannot be TPM_ALG_NULL and cannot be overridden.

If the handle for the signing key (*signHandle*) is TPM_RH_NULL, then all of the actions of the command are performed and the attestation block is “signed” with the NULL Signature.

NOTE 1 This mechanism is provided so that additional commands are not required to access the data that might be in an attestation structure.

NOTE 2 When *signHandle* is TPM_RH_NULL, *scheme* is still required to be a valid signing scheme (may be TPM_ALG_NULL), but the scheme will have no effect on the format of the signature. It will always be the NULL Signature.

TPM2_NV_Certify() is an attestation command that is documented in 31.16. The remaining attestation commands are collected in the remainder of this clause.

Each of the attestation structures contains a TPMS_CLOCK_INFO structure and a firmware version number. These values may be considered privacy-sensitive, because they would aid in the correlation of attestations by different keys. To provide improved privacy, the *resetCount*, *restartCount*, and *firmwareVersion* numbers are obfuscated when the signing key is not in the Endorsement or Platform hierarchies.

The obfuscation value is computed by:

$$obfuscation \coloneqq \mathbf{KDFa}(signHandle \rightarrow nameAlg, shProof, \text{“OBFUSCATE”}, signHandle \rightarrow QN, 0, 128) \quad (3)$$

Of the returned 128 bits, 64 bits are added to the *versionNumber* field of the attestation structure; 32 bits are added to the *clockInfo.resetCount* and 32 bits are added to the *clockInfo.restartCount*. The order in which the bits are added is implementation-dependent.

NOTE 3 The obfuscation value for each signing key will be unique to that key in a specific location. That is, each version of a duplicated signing key will have a different obfuscation value.

When the signing key is TPM_RH_NULL, the data structure is produced but not signed; and the values in the signed data structure are obfuscated. When computing the obfuscation value for TPM_RH_NULL, the hash used for context integrity is used.

NOTE 4 The QN for TPM_RH_NULL is TPM_RH_NULL.

 Copyright © TCG 2006-2020

If the signing scheme of *signHandle* is an anonymous scheme, then the attestation blocks will not contain the Qualified Name of the *signHandle*.

Each of the attestation structures allows the caller to provide some qualifying data (*qualifyingData*). For most signing schemes, this value will be placed in the TPMS_ATTEST.*extraData* parameter that is then hashed and signed. However, for some schemes such as ECDAA, the *qualifyingData* is used in a different manner (for details, see “ECDAA” in TPM 2.0 Part 1).

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

18.2 TPM2_Certify

18.2.1 General Description

The purpose of this command is to prove that an object with a specific Name is loaded in the TPM. By certifying that the object is loaded, the TPM warrants that a public area with a given Name is self-consistent and associated with a valid sensitive area. If a relying party has a public area that has the same Name as a Name certified with this command, then the values in that public area are correct.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a policySession→*commandCode* set to TPM_CC_Certify. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

The object may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary(). An object that only has its public area loaded cannot be certified.

NOTE 2 The restriction occurs because the Name is used to identify the object being certified. If the TPM has not validated that the public area is associated with a matched sensitive area, then the public area may not represent a valid object and cannot be certified.

The certification includes the Name and Qualified Name of the certified object as well as the Name and the Qualified Name of the certifying object.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

 Copyright © TCG 2006-2020

18.2.3 Detailed Actions

[[Certify]]

18.3 TPM2_CertifyCreation

18.3.1 General Description

This command is used to prove the association between an object and its creation data. The TPM will validate that the ticket was produced by the TPM and that the ticket validates the association between a loaded public area and the provided hash of the creation data (*creationHash*).

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The TPM will create a test ticket using the Name associated with *objectHandle* and *creationHash* as:

$$\mathbf{HMAC}(proof, (\text{TPM_ST_CREATION} \mid\mid objectHandle{\rightarrow}Name \mid\mid creationHash)) \tag{4}$$

This ticket is then compared to creation ticket. If the tickets are not the same, the TPM shall return TPM_RC_TICKET.

If the ticket is valid, then the TPM will create a TPMS_ATTEST structure and place *creationHash* of the command in the *creationHash* field of the structure. The Name associated with *objectHandle* will be included in the attestation data that is then signed using the key associated with *signHandle*.

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

objectHandle may be any object that is loaded with TPM2_Load() or TPM2_CreatePrimary().

[[CertifyCreation]]

18.4 TPM2_Quote

18.4.1 General Description

This command is used to quote PCR values.

The TPM will hash the list of PCR selected by *PCRselect* using the hash algorithm in the selected signing scheme. If the selected signing scheme or the scheme hash algorithm is TPM_ALG_NULL, then the TPM shall return TPM_RC_SCHEME.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The digest is computed as the hash of the concatenation of all of the digest values of the selected PCR.

The concatenation of PCR is described in TPM 2.0 Part 1, *Selecting Multiple PCR.*

NOTE 2 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

NOTE 3 A TPM may optionally return TPM_RC_SCHEME if *signHandle* is TPM_RH_NULL.

NOTE 4 Unlike TPM 1.2, TPM2_Quote does not return the PCR values. See Part 1, “Attesting to PCR” for a discussion of this issue.

18.5 TPM2_GetSessionAuditDigest

18.5.1 General Description

This command returns a digital signature of the audit session digest.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

If *sessionHandle* is not an audit session, the TPM shall return TPM_RC_TYPE.

NOTE 2 A session does not become an audit session until the successful completion of the command in which the session is first used as an audit session.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

If this command is audited, then the audit digest that is signed will not include the digest of this command because the audit digest is only updated when the command completes successfully.

This command does not cause the audit session to be closed and does not reset the digest value.

NOTE 3 If sessionHandle is used as an audit session for this command, the command is audited in the same manner as any other command.

NOTE 4 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

[[GetSessionAuditDigest]]

18.6 TPM2_GetCommandAuditDigest

18.6.1 General Description

This command returns the current value of the command audit digest, a digest of the commands being audited, and the audit hash algorithm. These values are placed in an attestation structure and signed with the key referenced by *signHandle*.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

When this command completes successfully, and *signHandle* is not TPM_RH_NULL, the audit digest is cleared. If signHandle is TPM_RH_NULL, *signature* is the Empty Buffer and the audit digest is not cleared.

NOTE 2 The way that the TPM tracks that the digest is clear is vendor-dependent. The reference implementation resets the size of the digest to zero.

If this command is being audited, then the signed digest produced by the command will not include the command. At the end of this command, the audit digest will be extended with *cpHash* and the *rpHash* of the command, which would change the command audit digest signed by the next invocation of this command.

This command requires authorization from the privacy administrator of the TPM (expressed with Endorsement Authorization) as well as authorization to use the key associated with *signHandle*.

18.6.3 Detailed Actions

[[GetCommandAuditDigest]]

18.7 TPM2_GetTime

18.7.1 General Description

This command returns the current values of *Time* and *Clock*.

NOTE 1 See 18.1 for description of how the signing scheme is selected.

The values of *Clock*, *resetCount* and *restartCount* appear in two places in *timeInfo*: once in TPMS_ATTEST.*clockInfo* and again in TPMS_ATTEST.*attested.time.clockInfo.* The firmware version number also appears in two places (TPMS_ATTEST.*firmwareVersion* and TPMS_ATTEST.*attested.time.firmwareVersion*). If *signHandle* is in the endorsement or platform hierarchies, both copies of the data will be the same. However, if *signHandle* is in the storage hierarchy or is TPM_RH_NULL, the values in TPMS_ATTEST.*clockInfo* and TPMS_ATTEST.*firmwareVersion* are obfuscated but the values in TPMS_ATTEST.*attested.time* are not.

NOTE 2 The purpose of this duplication is to allow an entity who is trusted by the privacy Administrator to correlate the obfuscated values with the clear-text values. This command requires Endorsement Authorization.

NOTE 3 If *signHandle* is TPM_RH_NULL, the TPMS_ATTEST structure is returned and *signature* is a NULL Signature.

18.8 TPM2_CertifyX509

18.8.1 General Description

The purpose of this command is to generate an X.509 certificate that proves an object with a specific public key and attributes is loaded in the TPM. In contrast to TPM2_Certify, which uses a TCG-defined data structure to convey attestation information, TPM2_CertifyX509 encodes the attestation information in a DER-encoded X.509 certificate that is compliant with RFC5280 *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile.*

As described in RFC, an X.509 certificate contains a collection of data that is hashed and signed. The full signature is the combination of the *to be signed* (TBS) data, a description of the signature algorithm, and the signature over the TBS data. The elements of the TBS data structure are DER-encoded values. They are:

1) Version [0] – integer value of 2 indicating version 3
2) Certificate Serial Number – integer value
3) Signature Algorithm Identifier – values (usually a collection of OIDs) identifying the algorithm used for the signature
4) Issuer Name – X.501 type *Name* to identify the entity that has authorized the use of *signHandle* to create the certificate.
5) Validity – two time values indicating the period during which the certificate is valid
6) Subject Name – X.501 type *Name* that identifies the entity that authorized the use of *objectHandle*
7) Subject Public Key Info – the public key associated with *objectHandle*,
8) Extensions [3] – a set of values that “provide methods for associating additional attributes with users or public keys and for managing relationships between CAs.”

NOTE 1: The numbers in square brackets (e.g., [0]) indicate application-specific tag values that are used to identify the type of the field.

NOTE 2: RFC 5280 describes two fields (issuerUniqueID and subjectUniqueID) but goes on to say: “CAs conforming to this profile MUST NOT generate certificates with unique identifiers.” The TPM does not allow them to be present.

The caller provides a partial certificate (*partialCertificate*) parameter that contains four or five of the elements enumerated above in a DER encoded SEQUENCE. They are:

1) Signature Algorithm Identifier (optional)
2) Issuer (mandatory)
3) Validity (mandatory)
4) Subject Name (mandatory)
5) Extensions (mandatory)

The fields are required to be in the order in which they are listed above.

NOTE 3: The TPM determines if the Signature Algorithm Identifier element is present by counting the elements.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

The optional Signature Algorithm Identifier may be provided by the caller. If it is not present, the TPM will generate the value based on the selected signing scheme. If the caller provides this value, then the TPM will use it in the completed TBS. The TPM will not validate that the provided values are compatible with the signing scheme. If the caller does not provide this field and the TPM does not have OID values for the signing scheme, then the TPM will return an error (TPM_RC_SCHEME).

NOTE 4: The TPM may implement signing schemes for which OIDs are not defined at the time the TPM was manufactured. Those schemes may still be used if the caller can provide the Signature Algorithm Identifier.

The Extensions element is required to contain a Key Usage extension. The TPM will extract the Key Usage values and verify that the attributes of *objectHandle* are consistent with the selected values (TPM_RC_ATTRIBUTES)(See Part 2, *TPMA_X509_KEY_USAGE*).

The Extensions element may contain a TPMA_OBJECT extension. If present, the TPM will extract the value and verify that the extension value exactly matches the TPMA_OBJECT of *objectKey* (TPM_RC_ATTRIBUTES). The element uses the TCG OID tcg-tpmaObject, 2.23.133.10.1.1.1. It is a SEQUENCE containing that OID and an OCTET STRING encapsulating a 4-byte BIT STRING holding the big endian TPMA_OBJECT.

signHandle is required to have the *sign* attribute SET (TPM_RC_KEY).

NOTE 5: See 18.1 for description of how the signing scheme is selected.

Authorization for *objectHandle* requires ADMIN role authorization. If performed with a policy session, the session shall have a policySession→*commandCode* set to TPM_CC_CertifyX509. This indicates that the policy that is being used is a policy that is for certification, and not a policy that would approve another use. That is, authority to use an object does not grant authority to certify the object.

If *objectHandle* does not have a sensitive area loaded, the TPM will return an error (TPM_RC_AUTH_UNAVAILABLE).

NOTE 6: The command requires that authorization be provided for use of *objectHandle.* An object that only has its *publicArea* loaded does not have an authorization value and the *authPolicy* has no meaning as the sensitive area is not present.

The TPM will create the Version, the Certificate Serial Number, the Subject Public Key Info, and, if not provided by the caller, the Signature Algorithm Identifier. These TPM-created values will be combined with the provided values to make a full TBSCerfificate structure (See RFC 5280, clause 4.1). The TPM will then sign the certificate using the selected signing scheme.

The TPM-created values will be returned in *addedToCertificate.* If the TPM creates the Signature Algorithm Identifier, it will be in *addedToCertificate* before the Subject Public Key Info. The TPM returns *tbsDigest* as a debugging aid.

NOTE 7: These returned fields allow the caller to unambiguously create a full RFC5280-defined TBSCertificate.

NOTE 8: This command was added in revision 01.53.

[[certifyX509]]

19 Ephemeral EC Keys

19.1 Introduction

The TPM generates keys that have different lifetimes. TPM keys in a hierarchy can be persistent for as long as the seed of the hierarchy is unchanged and these keys may be used multiple times. Other TPM-generated keys are only useful for a single operation. Some of these single-use keys are used in the command in which they are created. Examples of this use are TPM2_Duplicate() where an ephemeral key is created for a single pass key exchange with another TPM. However, there are other cases, such as anonymous attestation, where the protocol requires two passes where the public part of the ephemeral key is used outside of the TPM before the final command "consumes" the ephemeral key.

For these uses, TPM2_Commit() or TPM2_EC_Ephemeral() may be used to have the TPM create an ephemeral EC key and return the public part of the key for external use. Then in a subsequent command, the caller provides a reference to the ephemeral key so that the TPM can retrieve or recreate the associated private key.

When an ephemeral EC key is created, it is assigned a number and that number is returned to the caller as the identifier for the key. This number is not a handle. A handle is assigned to a key that may be context saved but these ephemeral EC keys may not be saved and do not have a full key context. When a subsequent command uses the ephemeral key, the caller provides the number of the ephemeral key. The TPM uses that number to either look up or recompute the associated private key. After the key is used, the TPM records the fact that the key has been used so that it cannot be used again.

As mentioned, the TPM can keep each assigned private ephemeral key in memory until it is used. However, this could consume a large amount of memory. To limit the memory size, the TPM is allowed to restrict the number of pending private keys – keys that have been allocated but not used.

NOTE The minimum number of ephemeral keys is determined by a platform specific specification

To further reduce the memory requirements for the ephemeral private keys, the TPM is allowed to use pseudo-random values for the ephemeral keys. Instead of keeping the full value of the key in memory, the TPM can use a counter as input to a KDF. Incrementing the counter will cause the TPM to generate a new pseudo-random value.

Using the counter to generate pseudo-random private ephemeral keys greatly simplifies tracking of key usage. When a counter value is used to create a key, a bit in an array may be set to indicate that the key use is pending. When the ephemeral key is consumed, the bit is cleared. This prevents the key from being used more than once.

Since the TPM is allowed to restrict the number of pending ephemeral keys, the array size can be limited. For example, a 128 bit array would allow 128 keys to be "pending".

The management of the array is described in greater detail in the *Split Operations* clause in Annex C of TPM 2.0 Part 1.

Level 00 Revision 01.59 **Copyright © TCG** 2006-2020 November 8, 2019

19.2 TPM2_Commit

19.2.1 General Description

TPM2_Commit() performs the first part of an ECC anonymous signing operation. The TPM will perform the point multiplications on the provided points and return intermediate signing values. The *signHandle* parameter shall refer to an ECC key and the signing scheme must be anonymous (TPM_RC_SCHEME).

NOTE 1 Currently, TPM_ALG_ECDAA is the only defined anonymous scheme.

NOTE 2 This command cannot be used with a sign+decrypt key because that type of key is required to have a scheme of TPM_ALG_NULL.

For this command, *p1*, *s2* and *y2* are optional parameters. If *s2* is an Empty Buffer, then the TPM shall return TPM_RC_SIZE if *y2* is not an Empty Buffer.

The algorithm is specified in the TPM 2.0 Part 1 Annex for ECC, TPM2_Commit().

19.3 TPM2_EC_Ephemeral

19.3.1 General Description

TPM2_EC_Ephemeral() creates an ephemeral key for use in a two-phase key exchange protocol.

The TPM will use the commit mechanism to assign an ephemeral key r and compute a public point $Q \coloneqq [r]G$ where G is the generator point associated with *curveID*.

20 Signing and Signature Verification

20.1 TPM2_VerifySignature

20.1.1 General Description

This command uses loaded keys to validate a signature on a message with the message digest passed to the TPM.

If the signature check succeeds, then the TPM will produce a TPMT_TK_VERIFIED. Otherwise, the TPM shall return TPM_RC_SIGNATURE.

If the key is in the NULL hierarchy, then *digest* in the ticket will be the Empty Buffer.

NOTE 1 A valid ticket may be used in subsequent commands to provide proof to the TPM that the TPM has validated the signature over the message using the key referenced by *keyHandle*.

If *keyHandle* references an asymmetric key, only the public portion of the key needs to be loaded. If *keyHandle* references a symmetric key, both the public and private portions need to be loaded.

NOTE 2 The sensitive area of the symmetric object is required to allow verification of the symmetric signature (the HMAC).

20.1.2 Command and Response

20.1.3 Detailed Actions

[[VerifySignature]]

20.2 TPM2_Sign

20.2.1 General Description

This command causes the TPM to sign an externally provided hash with the specified symmetric or asymmetric signing key.

NOTE 1 If *keyhandle* references an unrestricted signing key, a digest can be signed using either this command or an HMAC command.

If *keyHandle* references a restricted signing key, then *validation* shall be provided, indicating that the TPM performed the hash of the data and *validation* shall indicate that hashed data did not start with TPM_GENERATED_VALUE.

NOTE 2 If the hashed data did start with TPM_GENERATED_VALUE, then the validation will be a NULL ticket.

The *x509sign* attribute of keyHandle may not be SET (TPM_RC_ATTRIBUTES).

If the scheme of *keyHandle* is not TPM_ALG_NULL, then *inScheme* shall either be the same scheme as *keyHandle* or TPM_ALG_NULL. If the *sign* attribute is not SET in the key referenced by *handle* then the TPM shall return TPM_RC_KEY.

If the scheme of *keyHandle* is TPM_ALG_NULL, the TPM will sign using *inScheme*; otherwise, it will sign using the scheme of *keyHandle*.

NOTE 3 When the signing scheme uses a hash algorithm, the algorithm is defined in the qualifying data of the scheme. This is the same algorithm that is required to be used in producing *digest*. The size of *digest* must match that of the hash algorithm in the scheme.

If *inScheme* is not a valid signing scheme for the type of keyHandle (or TPM_ALG_NULL), then the TPM shall return TPM_RC_SCHEME.

If the scheme of *keyHandle* is an anonymous *scheme*, then *inScheme* shall have the same scheme algorithm as *keyHandle* and *inScheme* will contain a counter value that will be used in the signing process.

EXAMPLE For ECDAA, *inScheme.details.ecdaa.count* will contain the count value.

If *validation* is provided, then the hash algorithm used in computing the digest is required to be the hash algorithm specified in the scheme of *keyHandle* (TPM_RC_TICKET).

If the *validation* parameter is not the Empty Buffer*,* then it will be checked even if the key referenced by *keyHandle* is not a restricted signing key.

NOTE 4 If *keyHandle* is both a sign and decrypt key, *keyHandle* will have a scheme of TPM_ALG_NULL. If *validation* is provided, then it must be a NULL validation ticket or the ticket validation will fail.

20.2.3 Detailed Actions

[[Sign]]

21 Command Audit

21.1 Introduction

If a command has been selected for command audit, the command audit status will be updated when that command completes successfully. The digest is updated as:

$$commandAuditDigest_{new} \coloneqq \mathbf{H}_{auditAlg}(commandAuditDigest_{old} \mathbin{||} cpHash \mathbin{||} rpHash) \quad (5)$$

where

$\boldsymbol{H}_{auditAlg}$	hash function using the algorithm of the audit sequence
$commandAuditDigest$	accumulated digest
$cpHash$	the command parameter hash
$rpHash$	the response parameter hash

auditAlg, the hash algorithm, is set using TPM2_SetCommandCodeAuditStatus().

TPM2_Shutdown() cannot be audited but TPM2_Startup() can be audited. If the *cpHash* of the TPM2_Startup() is TPM_SU_STATE, that would indicate that a TPM2_Shutdown() had been successfully executed.

TPM2_SetCommandCodeAuditStatus() is always audited, except when it is used to change *auditAlg*.

If the TPM is in Failure mode, command audit is not functional.

 Copyright © TCG 2006-2020

21.2 TPM2_SetCommandCodeAuditStatus

21.2.1 General Description

This command may be used by the Privacy Administrator or platform to change the audit status of a command or to set the hash algorithm used for the audit digest, but not both at the same time.

If the *auditAlg* parameter is a supported hash algorithm and not the same as the current algorithm, then the TPM will check both *setList* and *clearList* are empty (zero length). If so, then the algorithm is changed, and the audit digest is cleared. If *auditAlg* is TPM_ALG_NULL or the same as the current algorithm, then the algorithm and audit digest are unchanged and the *setList* and *clearList* will be processed.

NOTE 1 Because the audit digest is cleared, the audit counter will increment the next time that an audited command is executed.
