

# Igf 1 Des Hypertrophy | Buy IGF1 DES 1mg | 99% Purity (USA Made) | Peptide Sciences

Naturally found in the brain, breast milk, and uterine tissue, IGF-1 DES stimulates hypertrophy and hyperplasia of a number of different cell lines. Research has shown this version of the protein to be more potent than standard IGF-1, mostly as a result of its enhanced bioavailability. IGF-1 DES is a peptide, simple of insulin-like development factor 1 accessible as a peptide. IGF-1 DES is entirely different compared to other products because of its strength, the subordinate of decreased authoritative of human Des [1-3]IGF-I compared to the vast majority of the IGF restricting proteins, which alters the live actions of IGF-I.

## **IGF-1 DES Introduction - Giant Lab igf-1 des 1mg USA ...**

Naturally found in the brain, breast milk, and uterine tissue, IGF-1 DES stimulates hypertrophy and hyperplasia of a number of different cell lines. Research has shown this version of the protein to be more potent than standard IGF-1, mostly as a result of its enhanced bioavailability. The form of DES is a shortened version of an IGF chain. potent as compared to LR3 and can provide ten times the power compared to the main IGF-1. DES has a half-life of about half an hour, which is due to the thinness of this chain. So, you should be injected in the area you want to grow! DES is the best choice for long-term injections.

## **IGF-1 DES - Humapeptide**

IGF-1 DES is 10 times more potent than IGF-1 in stimulating hypertrophy and proliferation of cells because it is not affected by IGF-1 binding proteins and therefore is more bioavailable. There is interest in using the peptide to induce anabolism in catabolic conditions (e.g. chronic illness) and in the treatment of inflammatory bowel disease.

Accordingly, the hypertrophic effect of IGF-1 was greater in the myostatin null background [25]. Myostatin signaling is mediated by activin type II receptors (ActRIIA and ActRIIB) and activin type I receptors (ALK4 and ALK5), leading to phosphorylation of Smad proteins (Smad2 and -3). ## Mechanisms of IGF-1-Mediated Regulation of Skeletal Muscle ...

The most important factor to consider is IGF-1's ability to achieve hyperplasia. When you use steroids, they will help the body through hypertrophy, which means you are increasing the size of the existing muscle cells. On the other hand, IGF-1 will cause hyperplasia, which means you are actually increasing the number of cells in the muscle tissue.

Regardless, here are some of the most well-understood benefits of IGF-1. Helps build muscles. The main reason that most people are interested in using IGF-1 is that it helps to build muscle by enhancing hypertrophy (muscle growth). IGF-1 helps the body activate a number of processes that also encourage other growth factor hormones to flourish. [here are the findings](#)
