

# Tailored Tapwater™ Quick Install Guide

(Video At [www.hydroviv.com/installation](http://www.hydroviv.com/installation))

1. Identify the cold water shutoff valve by turning on the faucet cold water, and seeing which shutoff valve makes the water flow stop (usually on the right). Keep the water off during installation.
2. Hold the valve securely with your hand while using the wrench to loosen the nut on the faucet cold water line.

3. Slide the plastic ring on included plastic tube so it is 1/4 inch from the brass-reinforced end of the tube. Connect this end of the tube to the cold water shutoff valve with the metal nut. Tighten the nut to "finger tight" plus an additional full turn with a wrench.
4. Find a location in the cabinet where the hoses will easily reach Tailored Tapwater without crimping or tight bends in the tube. A good place to put the system is often on the cabinet sidewall closest to the cold water shutoff valve.

5. Connect the faucet cold water line to the brass fitting on Tailored Tapwater. The nut should be tightened to "finger tight," plus an additional turn with a wrench.
6. Firmly insert the plastic tube into the white fitting until the tube bottoms out. Tug the plastic tube to set the connection.
7. Restore the cold water flow by turning the cold water valve counter-clockwise. When the water is turned on the first time, it is normal to hear a "whooshing" noise as air goes through, and for the first bit of water to be dark.
8. Run water through the system for 3 minutes to properly flush the cartridge. For the first day or two, the water may appear cloudy from tiny air bubbles as they are expelled from the cartridge. This is temporary, and the water is safe to drink!
9. Check the system periodically for leaks. We also recommend using a leak detector to be on the safe side.
10. Do not worry if the flow rate is a little bit slower initially, because it increases over the first week as the filter breaks in.
