A man with dark, wavy hair and a mustache is shown in profile, wearing a brown cable-knit sweater. He is holding a large, green cannabis plant with serrated leaves and budding flowers in a rustic, perforated terracotta pot. He is leaning in and smelling the plant. The background is a textured, grey-blue wall.

THE CANNA- QUANTUM REALM

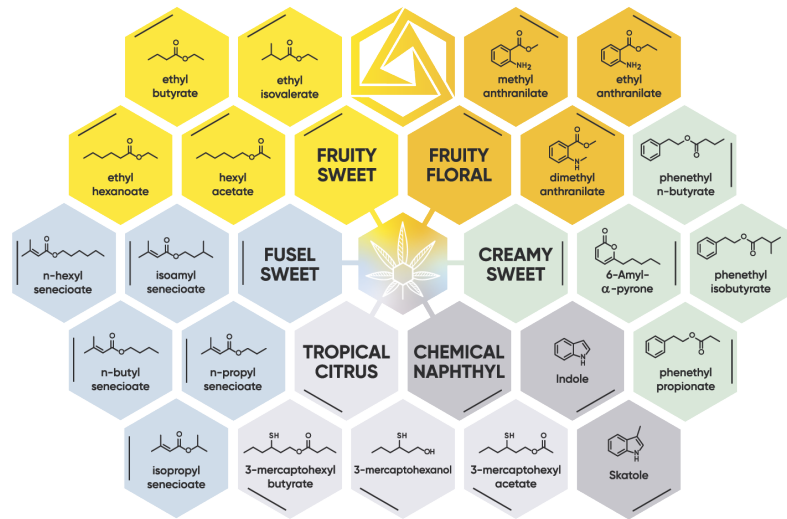

Abstrax and the research team see this as a partial response to the modern pushback to the classic indica, sativa, and hybrid classification system we've leaned on up to this point. As the cannabis industry develops more modern ways of labeling and portraying the different varieties of cannabis, it's looking for new terms to replace indica and sativa, and smell has emerged as a dowsing rod as competitions divide strains between candy, citrus, and gas. Much of the marketing focus on educating base-level consumers past sativa and indica has shifted toward trying to describe to shoppers what these aromatic compounds mean concerning the taste, smell, and psychoactive effects of a strain. It makes sense since, as the research points out, they appear in high amounts, making them a seemingly perfect identifier for classification.

Contrastingly, the research asserts that we might be trading one generalization for another in our use of terpenes, pointing to an additional study—"The phytochemical diversity of commercial cannabis in the United States," published in *PLoS One* in May 2022—which concluded that in the United States, all cannabis falls into one of three terpene-dominant categories: terpinolene/ β -myrcene, D-(+)-limonene/ β -caryophyllene, or β -myrcene/pinene.

The authors point out that through this system, strains with very different smells ended up in the same groups together. With its skunky, woody aroma, Dogwalker OG wound up next to Tropicana Cookies and Purple Punch, two cultivars with very contrasting smells. Meaning that you can't always assume something will smell a certain way due to high percentages of certain terpenes.

"Taken together, these results strongly suggest that while aroma is a key property in differentiating cannabis varieties and user preferences, the importance of terpenes appears to be overstated," researchers wrote.

The team concluded that terpenes had less of a correlation with the sought-after attributes of a lot of "exotic" cannabis strains and that it must be these alternate classes of compounds at work.

The study identified a wide variety of aroma classes, each with diverse functionality, that are responsible for some of the most desirable aromatic qualities found in modern cannabis. Two such classes include tropical volatile sulfur compounds (VSCs), which are responsible for the citrus notes in Tropicana Cookies or Tangie, and heterocyclic compounds like indole and skatole, which produce the rich, intense scent in strains like GMO. They also identified a class of chemicals called flavorants that includes alcohols, ketones, and esters, that go beyond terpenes in affecting the smells and tastes of cannabis. Though found in small amounts, they believe these compounds play a major role by combining to create many of the diverse tastes in modern "exotic" strains like Apple Fritter or Zkittlez.

"The discovery of these compounds will play a crucial role in validating cannabis's authenticity and accurately classifying cannabis varieties in the future," says Max Koby, CEO and co-founder of Abstrax.

Koby also said that utilizing these previously undiscovered cannabis compounds would allow Abstrax to create "the most flavorful and authentic cannabis flavors," which will elevate the level of the terpene blends and isolate it sells, but also benefit everyone in the space. Consumers can finally have a better toolkit to identify what flavors and feelings they enjoy most. Cultivators, breeders, and brands could someday use this knowledge to better understand which plant components drive these sweet fruit flavors versus the savory ones.

"This research helps us better understand flavor in the cannabis experience, allowing us to better educate our customers and select phenos for our genetic library," says research co-author Brad Melshenker, co-CEO of 710 Labs.

One of the more exciting benefits that Abstrax identified for this research was its ability to provide a jumping-off point for researchers and packagers to discover the best way of preserving these specific compounds and provide cannabis with a better shelf life.

With additional research planned, Abstrax has announced a partnership to create educational content that helps tell the story of the revelations brought about by its discoveries. Somebody reach out to Paul Rudd. Just like *Antman* explored and expanded upon the understanding of the microscopic quantum realm the technology employed here shows us there's so much more happening inside the plant than we've ever imagined.

Abstrax believes "we stand at the dawn of a new era in cannabis understanding" and that the microcosm of additional compounds inside these plants is part of a secret roadmap researchers are just now learning to draw. This new research will allow us to look for and provide solutions to many of the problems that have arisen from the swift evolution of cannabis from evil weed to essential service. Maybe someday, in a galaxy far, far, away, an android will extend a glass jar to smell the nugs instead of watching an image spin on a budtender's holopad. **HT**
