**Warning:**

Do no drill any holes in the aircraft or aircraft structure that will result in less than recommended edge or fastener spacing distances. Reference your aircraft's structural repair manual or Advisory Circular 43.13 for more information. If the installation requires less than recommended distances, do not proceed with the installation and contact Trutrak Flight Systems for further instruction.

2. Controller Installation

2.1. Mounting Considerations

The Vizion controller unit is designed to mount in the aircraft instrument panel within view and reach of the pilot. Maximum recommended viewing angle should be no more than 20 deg. The maximum mounting angle the Vizion can accommodate is 10 degrees longitudinal (pitch) axis and 0 degrees lateral (roll or yaw) axis. The location should be such that the controller unit is not blocked by the glare shield on top, or by the throttles, control yoke, etc. on the bottom. Use appropriate aircraft installation standards for mounting and support of the autopilot controller. *After completion of mechanical installation, apply torque seal (Cross Check A498M or equivalent) to all servo and servo linkage fasteners.*

2.2. Wiring Considerations

Use AWG #24 or larger wire for all connections unless otherwise specified. The standard crimp pin contacts supplied in the connector kit are compatible with up to AWG #20 wire. AWG #20 shall be used for all power and ground connections. Do not attach any wires to the outside of the autopilot controller or route high current wires within six (6) inches of the controller. Ensure that routing of the wiring is not exposed to sources of heat, RF or EMI. Check that there is ample space for the cabling and mating connectors. Avoid sharp bends in cabling and routing near aircraft control cables. Do not route the COM antenna coax within twelve (12) inches of any autopilot components.

- Ensure that the autopilot master switch is mounted in a location that is easily accessible to the pilot / crew.

- Ensure that the autopilot circuit breaker is mounted in a location that is easily accessible to the pilot / crew.

- Ensure that the Control Wheel Steering button / emergency autopilot disconnect switch is mounted on the pilot’s yoke / stick. This button must be installed, must be red in color, and must be labeled as AP CWS or AP DISCO or AP CUTOFF.
• Ensure that the Emergency Level button is located in a clearly visible and accessible portion of the panel. This button must be accessible to both pilot and copilot.

2.3. Pitot / Static Connection
All TruTrak autopilots require connections to the pitot and static systems. The preferred method of this connection would be tee fittings near the aircraft’s altimeter. The static line for the autopilot requires due care in its construction, as excessive lag or insufficient static orifices can cause the autopilot to oscillate (hunt) in pitch. Although there is compensation within the autopilot sufficient to handle moderate amounts of lag, the importance of a good static port and line cannot be overstated. In some cases problems can be caused by having a large number of devices (including the autopilot) connected to a single, insufficient, static port. In other cases, the static line itself is adequate but there are one or more devices connected to the same line, one of which has a large static reservoir. A simple remedy for this problem if it occurs is a tee-fitting near the static port, and a dedicated line to the autopilot only. Obviously, an insufficiently-large orifice coupled with large static reservoirs can aggravate the problems associated with lag.

2.4. RFI / EMI Considerations
The autopilot controller is shielded and does not generate any appreciable level of electromagnetic interference. Moreover, the servo lines (except for power and ground) are low-current and cannot contribute to RF interference. The servo power and ground lines do have switching currents through them, but so long as there are no parallel runs of servo power and ground lines with such things as poorly shielded antenna lines or strobe light power lines, there is no need to shield the servo harnesses.

The autopilot itself has been internally protected from RF interference and has been tested under fairly extreme conditions, such as close proximity to transmitting antennas. However, it is always good practice to ensure that such antennas are properly shielded and not routed directly over or under sensitive panel-mounted electronic equipment. Most problems in this area are the result of improper RF shielding on transmitting antennas, microphone cables, and the like. The most sensitive input to the autopilot is the Control Wheel Steering switch input. This line should not be routed in parallel with transmitting antennas or other sources of known RF interference. If necessary, it can be shielded with the shield connection to pin 13 of the autopilot connector.
# 2.5 Vizion Electrical Pin Out

The table below provides a brief explanation of each pin function on the main 25-pin connector P101.

3. Controller Cut-outs and Dimensions

3.1. Flat Pack Dimensions (8000-175 / 8000-185)
3.2. Flat Pack Panel Cut-out
3.3. 2-1/4” Round Dimensions (8000-174 / 8000-183)
3.4. 3-1/8” Round Dimensions (8000-176 / 8000-184)
4. GPS Setup

For known setup and cable information to connect GPS units to the Vizion autopilot, see the document “Approved GPS List (186)” on the TruTrak website Certified Documents and Manuals page. This document provides setup information for panel mounted and handheld GPS units that have been verified to be compatible with TruTrak autopilots.

If your GPS is not included in the Approved GPS List (186), consult your GPS manual for NMEA output setup. The autopilot must have a direct RS-232 connection with the handheld GPS. To allow easy removal of the handheld GPS, a 9 pin D subminiature connector in your panel is recommended, which will also allow the use of the aircraft electrical system to power the handheld GPS.

5. Vizion Ground Checkout

Once installation and setup of the autopilot are complete, (see appropriate appendix for servo installation, wiring harness routing, and autopilot controller settings) a ground checkout is required before the first flight of the system. This procedure will verify correct servo direction and pitot / static system connection.

The following steps should be used to do a ground checkout prior to powering or engaging autopilot in flight.

1. Apply power to autopilot and servos and GPS (if equipped). If GPS equipped ensure a GPS has a position fix.
2. Verify autopilot display shows either NO FIX or GPS OK in the upper left.
3. Center both aileron and elevator control surfaces.
4. Using a calibrated PITOT / STATIC test box, connected to both PITOT and STATIC ports of the aircraft, apply an airspeed to the system within above MINIMUM AIRSPEED but below MAXIMUM AIRSPEED (These values are given in the appropriate appendix for the aircraft make / model).
5. Engage the autopilot with a PRESS of the KNOB on the face of the autopilot.
6. Verify that both roll and pitch servos have engaged and are holding aircraft controls.
7. Adjust PITOT pressure to lower the airspeed to below MINIMUM AIRSPEED.
8. Verify that autopilot display shows MIN AS within approximately 3 knots of calibrated airspeed indicator on test box.
9. Adjust PITOT pressure to increase the airspeed to above MAXIMUM AIRSPEED.
10. Verify that autopilot display shows MAX AS within approximately 3 knots of calibrated airspeed indicator on test box.
11. Return PITOT pressure to normal range between MINIMUM and MAXIMUM AIRSPEED.
12. Adjust STATIC pressure to lower altitude at a few hundred feet per minute.
13. Verify that stick or yoke moves aft.
14. Adjust STATIC pressure to increase altitude at a few hundred feet per minute.
15. Verify that stick or yoke moves forward.
16. ROTATE KNOB clockwise to command a turn to the right.
17. Verify that stick or yoke moves to roll the aircraft to the right.
18. ROTATE KNOB counter-clockwise to command a turn to the left, make sure to rotate far enough to actually command a left turn.
19. Verify that the stick or yoke moves to roll the aircraft to the left.
20. Disengage autopilot with a PRESS of the CWS button.
21. Verify that servos have disconnected, autopilot display shows AP OFF, and controls are again free.
22. Center both aileron and elevator control surfaces.
23. Engage autopilot with a PRESS of the AP LEVEL button.
24. Verify that both roll and pitch servos have engaged and are holding aircraft controls.
25. PRESS KNOB to move cursor to SVS and ROTATE KNOB clockwise to select a 300 fpm VS climb.
26. Verify that stick or yoke moves aft.
27. Apply a force to the stick or yoke to resist the aft movement
28. Verify that the center of the autopilot display shows the letters UP with an arrow pointing up above them. (this is the indication to trim the aircraft for nose up).
29. PRESS KNOB to move cursor to SVS and ROTATE KNOB counter-clockwise to select a -300 fpm VS climb.
30. Verify that stick or yoke moves forward.
31. Apply a force to the stick or yoke to resist the forward movement
32. Verify that the center of the autopilot display shows the letters DN with an arrow pointing down below them (this is the indication to trim the aircraft for nose down).
33. Disengage the autopilot with a PUSH and HOLD of the knob, release when the display shows AP OFF.
34. Verify that both servos have disconnected and controls are again free.

If steps 1-34 are all verified then the autopilot is ready for a confirmation flight.

6. Vizion First Flight Checkout
Prior to performing Vizion first flight, it is strongly recommended that the pilot be familiar with the operation of the Vizion system. Reading though both the Vizion AFMS (TruTrak Doc 176) and the Vizion Operating Manual (TruTrak Doc 167) is
recommended. It would also be beneficial to spend some time operating the Vizion autopilot system on the ground to ensure familiarity with modes and controls.

1. Apply power to autopilot and servos and GPS (if equipped). If GPS equipped ensure GPS has a position fix.
2. If GPS equipped, verify autopilot display shows TRK (if aircraft is moving at greater than 15 knots ground speed) and the current track in the upper left.
3. Synchronize autopilot altimeter to aircraft altimeter, CLICK ALT button two times and ROTATE KNOB until displayed altitude matches that of the aircraft altimeter.
4. Engage the autopilot with a CLICK of the KNOB on the face of the autopilot.
5. Verify that both roll and pitch servos have engaged and are holding aircraft controls. The autopilot should synchronize to the current track and vertical speed being flown at the time.
6. ROTATE KNOB clockwise to command a turn of about 60 degrees to the right. (If not GPS equipped, then command a 10-15 degree bank angle)
7. Verify that the aircraft follows the commands and rolls out within a few degrees of the selected track. (If not GPS equipped, the turn must be manually stopped by rotating the KNOB to zero bank)
8. ROTATE KNOB counter-clockwise to command a turn of about 60 degrees to the left.
9. Verify that the aircraft follows the commands and rolls out within a few degrees of the selected track. (If not GPS equipped, the turn must be manually stopped by rotating the KNOB to zero bank)
10. If GPS equipped, enter a flight plan or direct to into the GPS.
11. CLICK MODE button to engage either GPS NAV or GPSS.
12. Ensure that autopilot follows GPS flight plan / direct to.
13. If Aspen / G5 equipped, select Aspen / G5 ARINC source.
14. CLICK MODE button to engage ASPEN / EXT HDG, EXT ALT mode.
15. Ensure that autopilot follows heading bug and / or altitude bug.
16. Disengage autopilot with a CLICK of the CWS button.
17. Verify that servos have disconnected, autopilot display shows AP OFF, and controls are again free.
18. Engage autopilot with a CLICK of the AP LEVEL button.
19. Verify that both roll and pitch servos have engaged and are holding aircraft controls. (Display will show BANK mode for several seconds and then will transition to TRK mode if GPS equipped)
20. CLICK ALT button to enter altitude select mode.
21. ROTATE KNOB to select an altitude approximately 300 feet lower, CLICK KNOB to move cursor to VS field, ROTATE KNOB to select a climb rate of approximately -300 fpm. CLICK KNOB to enter altitude select mode.
22. Verify that aircraft descends to and levels off within 20 feet of selected altitude (If trim indication appears, trim aircraft accordingly).
23. Disengage the autopilot with a PRESS and HOLD of the knob, release when the display shows AP OFF.
24. Ensure that AEP is in STBY mode. Display should show AEP STBY, if display does not show AEP STBY, CLICK MODE button to toggle AEP mode from AEP OFF to AEP STBY.
25. Manually fly aircraft to bank angle of approximately 45 degrees, verify that AEP engages (Display shows AEP ACTIVE) and roll servo puts force into the control system moving controls in a direction to lower the bank angle.
26. Verify that AEP goes back to STBY when bank angle decreases to approximately 35 degrees.
