

# FACTS AND FALLACIES ABOUT INHALED CORTICOSTEROIDS

## What Are Corticosteroids?

Corticosteroids, e.g. cortisone, are part of a family of substances which are produced by the body to help it function normally. They are natural agents that prevent inflammation. The corticosteroids used to treat asthma are similar to your own naturally occurring cortisone.

Corticosteroids are not the same as the anabolic steroids that some athletes and bodybuilders use to enhance their muscles and gain strength. Anabolic steroids can have serious side effects.

#### Why Should I Use Corticosteroids?

The symptoms you may experience with asthma (such as difficulty in breathing, wheezing, coughing and waking up at night) occur when the small tubes that carry air into your lungs become over sensitive to a variety of "triggers" and react by becoming narrower. This makes it harder for air to move in and out of your lungs, so that breathing gets more difficult.

Your breathing tubes narrow because they become inflamed (swollen and red like the effects you see with a joint sprain) and the muscles tighten around your tubes with excess mucus being produced.

Corticosteroids (brown/orange inhalers) are preventers. They are the most effective agents for treating the swelling and inflammation in your breathing tubes. In the long term, this will help to reduce the number of problems you have with asthma, decrease the amount of medication you need and help prevent your asthma from interfering with your enjoyment of life. The important thing is to take your preventer regularly.

Relievers (blue inhalers) have only short-term benefits. They help to relieve your symptoms by relaxing the muscles around your breathing tubes. Use them when you need instant relief. Relievers do not affect the swelling and inflammation, which are the underlying problems. If you don't get rid of the inflammation, you will continue to have the symptoms (like painting over rust without removing the rust first). You may even make your asthma worse.

### Fallacies

I have heard that corticosteroids may cause unpleasant side effects like stunting growth, making bones brittle and causing a "moon face" look. Will this happen to me?

Will inhaled corticosteroids give me big ugly muscles?

*Will I get addicted to my inhaled corticosteroids?* 

I've just started using inhaled corticosteroids and I don't feel any better, so does that mean they aren't working?

My inhaled corticosteroid medication makes me cough when I use it. Is it making my asthma worse?

When I don't have any asthma symptoms do I still need to take my inhaled corticosteroids?

# If you have any concerns always see your doctor

#### **Facts**

These effects are related to the use of oral forms of corticosteroids. Now the majority of asthma patients use inhaled asthma medications. Although high doses of inhaled corticosteroids may have side effects, they should not occur with the doses normally used.

Inhaled corticosteroids are not the same as the anabolic steroids used by bodybuilders. They do not have this muscle building effect.

No, the inhaled corticosteroids work by replacing a defense mechanism which is missing in your body. Therefore, when you use the inhaled corticosteroids your lungs work normally, much the same as a diabetic patient lives normally when taking insulin regularly.

Inhaled corticosteroids need to be taken for a week or two before you will notice a difference in your symptoms. They don't work immediately, the way relievers do.

Not necessarily. Some people cough because they react to the additives in their inhaler. This may make it difficult to get the medication into your airways and you may not get the desired benefit. Try an additive free inhaler.

Yes, you still do. Inhaled corticosteroids are preventative medications and need to be taken every day to stop asthma attacks occurring. You might not feel ill today, but if you don't take your inhaled corticosteroids you may feel ill tomorrow.
