Introduction

Understanding the growth stages of cereals crops and how to identify them is key to successful cropping and pest management decisions.

Although there are several growth staging methods, this guide is based on the Feekes scale, which is a popular tool used in the field. It has eleven development stages with some stages having more detailed subdivisions.

The Zadoks scale is the standard scale used in research and has ten development stages, each stage having ten subdivisions. Both scales are useful to know, so this guide cross-references the Zadoks equivalents to the Feekes.

This guide uses winter wheat as an example.

However, the methods generally apply to other cereals as well and at the back of the guide are sections that showcase barley, oats, rye and triticale.

A few notes on growth staging plants:

- Select plants that represent at least 50% of the field
- Dig plants (if possible), so you can assess the entire plant
- Start at the base of plant and work your way upward
- Use a knife to split the stems and sheaths
- Look and feel for nodes

Basic wheat anatomy

This illustration shows the basic anatomy of a Feekes 2 plant; the intention of the drawing is to illustrate and annotate an ideal plant

Plants in the field are rarely ideal and are often missing leaves, tillers, etc.

During the vegetative stages, the **auricles** are often a good way to distinguish between different cereal crops

Wheat

Auricles blunt and hairy; leaf sheath and blade always hairy; ligule medium length; leaf blades twist clockwise

Feekes scale for cereal growth stages

SEEDLING GROWTH	1 One shoot, first leaf through coleoptile
TILLERING	2 Tillering begins; main shoot and one tiller
	3 Tillers formed; leaves often twisted In some varieties, plant may be prostrate in appearance
	4 Leaf sheaths lengthen; beginning pseudostem erection
	5 Leaf sheaths fully elongated to form strongly erect pseudostem
STEM EXTENSION	6 First node of stem visible at base of shoot; jointing
	7 Second node of stem formed; next-to-last leaf just visible
	8 Flag leaf visible but still rolled up
	9 Ligule of flag leaf just visible
	10 Flag leaf sheath completely grown out; booting
HEADING	10.1 First awns of head just visible
	10.2 1/4 of heading process complete
	10.3 1/2 of heading process complete
	10.4 3/4 of heading process complete
	10.5 All heads out of sheath
FLOWERING	10.5.1 Beginning of flowering
	10.5.2 Flowering complete to top of head
	10.5.3 Flowering complete at base of head
	10.5.4 Flowering complete; kernel watery ripe
RIPENING	11.1 Kernel milky ripe; milk stage
	11.2 Kernel mealy ripe; soft but dry consistency; soft dough stage
	11.3 Kernel hard; difficult to divide with thumbnail; hard dough stage
	11.4 Kernel harvest ready; straw dead

	98	Secondary dormancy induced		
	99	Secondary dormancy lost		

Germination

Germination begins when the **dry seed** imbibes water and begins to expand

Zadoks 00
Dry seed

Zadoks 01
Start of imbibition

radicle
The first root

Zadoks 05
Radicle emerged from seed

coleoptile
The round sheath that protects the first leaf

Zadoks 07
Coleoptile emerged from seed

Planting depth and soil temperature influence the duration of the germination stages

Zadoks
00-09

The **first true leaf** emerges through the coleoptile's tip

Zadoks 09
Leaf just at coleoptile tip

The **coleoptile** stops growth when it encounters light above the soil surface

seed

The **seminal roots** begin developing

Seminal roots are fibrous and are produced by the seed

A close-up photograph of several young corn plants growing from dark, moist soil. The plants are in the early stages of growth, with one prominent shoot and its first leaf visible. The leaves are a vibrant green color and have a distinct parallel vein pattern. The background is a bright blue sky with some light, wispy clouds. The overall scene is well-lit, suggesting a sunny day.

Feekes

1

Zadoks 10

EMERGENCE | **Feekes 1** | One shoot formed;
first leaf through coleoptile

Feekes
1

This is an important time to check plants for **uniform emergence**; planting depth and soil temperature influence the length of this stage

main shoot

Feekes
2

Zadoks 21

TILLERING | **Feekes 2** | Tiller development begins

Tillers produced **in the fall** will contribute more to grain yield than those produced in the spring

Feekes
2

main shoot

tillers

The **crown** forms between the seed and soil surface

Feekes

2

main shoot

tiller

tillers

prophyll

The independent
sheath at the
base of each tiller

tiller

The secondary
root system starts
developing

Are tillers important?

Tillers are absolutely necessary for high yields

Feekes
2

1 can
produce
planted seed

4-5

tillers

are also called
axillary or
side shoots;
not all tillers
will complete
development
and produce
grain

The **total numbers of tillers**
a plant produces is determined by both
environmental conditions and **genetic potential**

KEY YIELD COMPONENT

A **tiller** is capable of forming a single head (spike)

The **head** is made up of spikelets

Each **spikelet** contains individual florets

Individual **florets** can produce a single **kernel**

In Wisconsin, the recommended
planting date range for optimal
tiller development in winter wheat
is **September 20 to October 10**

Feekes
3

Zadoks
22-29

TILLERING | Feekes 3 | Tillering completed

Tillers with 3 or more leaves will be nutritionally independent from the main shoot

Feekes
3

main shoot

★ tillers

The secondary root system undergoes extensive development

Feekes
3

FEEKES 3 CAN OCCUR IN FALL OR SPRING

because winter wheat development is dependent on both temperature and planting date

FEEKES 3 FALL

Tillering completes in fall,
winter dormancy occurs

FEEKES 3 SPRING

Tillering begins in the fall,
winter dormancy occurs,
tillering completes in the spring

What happens during winter dormancy?

Vernalization!

When temperatures fall below 50 degrees Fahrenheit
for typically 3-6 weeks, the plant initiates

differentiation

the growing point changes from
vegetative or leaf producing to
reproductive or spikelet producing

The growing point is at the **double ridge stage** and
is still protected in the crown below the soil surface

The number of florets initiated during this stage will
determine the **potential** number of kernels per head

KEY YIELD COMPONENT

Dig plants as soon as the soil thaws, bring inside and place in a warm (preferably moist) area for a few days, then check for root regrowth

regrowth

Root regrowth will develop from the crown and appear a vibrant white compared to the older roots

Feekes
3

FACTORS AFFECTING WINTER SURVIVAL

-  Good snow cover acts as insulator; keeps soil temperature from going below critical levels
-  Cyclic freezing and thawing increases injury from ice crystal growth in tissue
-  Mid-winter thaw and rain cause flooding at the base of the plants; crowns can die at warmer temperatures
-  Ice encasement traps carbon dioxide and suffocates plant by inhibiting respiration
-  Frost heaving can push root system out of ground, leaving plants vulnerable and weak

4 STEPS TO ASSESS STANDS IN EARLY SPRING

- 1 Venture out and get a general overview of the fields** — vibrant green patches may be interspersed with drab brown areas, but brown does not always indicate winter-killed plants
- 2 Check for winter survival** — identify several representative plants and 1) dig plants and bring inside to check for root regrowth **or** 2) wait a week and revisit to check for regrowth in the field
- 3 Do a plant count** —
below 12 live plants per square foot is an automatic replant; 12-15 live plants per square foot requires more consideration for a replant decision; 15-22 live plants per square foot may recover and reach maximum yield potential; over 22 live plants per square foot means you're good to go!
- 4 Consider a nitrogen application** — the optimal time to apply nitrogen to winter wheat in Wisconsin is during green up; for recommendations and rates, consult UW-Extension publication A2809 *Nutrient Application Guidelines for Field, Vegetable and Fruit Crops in Wisconsin*

In Wisconsin, the growth stage at green up can be **Feekes 3** or **Feekes 4** depending on planting date and environmental conditions

**GREEN
UP**

→ **How to do a plant count**

Count the number of plants in a 3-foot length

Do this for at least 3 areas

Take the average of the counts

Multiply that number by 4

Then divide by the row width (inches)

EXAMPLE

*The 3 counted areas have
40, 35 and 45 plants*

*Add 40, 35 and 45 and then
divide by 3, the average = 40*

Multiply 40 x 4 = 160

*Divide 160 by 7.5 inches =
21 plants/square foot*

Feekes

4

Zadoks 30

TILLERING | **Feekes 4** | Leaf sheaths lengthen,
pseudostem erection begins

**This is an important time for weed control
and/or nitrogen applications**

Wheat plants have a *pseudostem*, which is a false stem composed of concentric rolled leaf sheaths that surround the growing point (the developing head)

During this stage, these leaf sheaths lengthen,
making the plants stand more upright

Feekes

4

This is the last stage that some herbicides
can be used without risk of injury!

Always check and follow herbicide labels

Feekes

5

Zadoks 30

TILLERING | **Feekes 5** | Leaf sheaths fully
elongated, pseudostem strongly erect

plants cut at
soil surface

Feekes
5

As the **developing head** is pushed up into the pseudostem, it becomes more vulnerable to damage

less than 1/8 inch

The growing point is at the **terminal spikelet stage** and about 1/4 inch above the crown

The **number of spikelets per head** has been determined by this stage

KEY YIELD COMPONENT

Feekes
6

1st node

1st node

As the head moves up the stem, it is vulnerable to freeze injury during low temperatures!

1st node

A node is an area of active cell division from which leaves, tillers and adventitious roots develop

1st node

leaves
removed to
show nodes

The jointing stage is when the **internodal tissue** begins to elongate and pushes the **four nodes** that are stacked in the crown upward, similar to how a telescope works

A leaf arises from each of these nodes, with the 4th node giving rise to the flag leaf — the last leaf the plant produces

Feekes 6 plant
shown with all
leaves intact

Feekes
6

*From this growth stage forward,
**broken stems due to wheel
traffic will result in yield loss!***

*The developing head is
moving up the stem and
needs to be protected*

***The number of tillers that form heads
has been determined by this stage***

KEY YIELD COMPONENT

Feekes
7

SCOUT NOW!

and nodes

Feekes
8

flag leaf

This is a **critical time** to make foliar fungicide application decisions!

flag leaf

FLAG LEAF FACTS

The flag leaf accounts for over 50% of the photosynthates used for grain development, a.k.a **YIELD**

It must be protected from disease or insect damage to ensure the plant's full yield potential

Fungicide application decisions to protect the flag leaf should be made based on **presence** and **severity** of disease on the two leaves immediately below it

Feekes
8

The **flag leaf** arises from the 4th node

#4

This leaf arises from the 2nd node

#2

This leaf arises from the 3rd node

#3

HOW DO YOU KNOW IF IT'S THE FLAG LEAF?

Identify the leaf arising from the 1st node

Call this leaf #1 and count upward

The flag leaf will be leaf #4

location of developing head

4th node

3rd node

2nd node

#1

This leaf arises from the 1st node
(see tip on Feekes 7)

sheaths removed to show head and nodes

Kernel size is determined by crop health and water/nutrient availability beginning now and continuing through grain fill

KEY YIELD COMPONENT

Feekes

9

Zadoks 39

STEM EXTENSION | **Feekes 9** | Flag leaf fully emerged from the whorl; ligule just visible

flag leaf

ligule

leaf collar

The area on the outer side of the leaf where the blade and the sheath join

The ligule is a narrow membranous scale on the inner side of the leaf sheath at its junction with the blade

Feekes
10.5

Zadoks 59

HEADING | **Feekes 10.5** | Head completely
emerged from the leaf sheath

The image shows four wheat spikes against a white background. The spikes are green and elongated, with the grain heads clearly visible. The spikes are arranged diagonally across the frame.

This stage completes the heading process

Feekes
10.5

Feekes

10.5.1

Starting now and continuing 5-7 days **after this stage** is the optimum time for fungicide application to suppress *Fusarium* head blight (FHB), also called head scab

Flowering begins slightly above the middle portion of the head and continues towards the top

This stage begins shortly after the head has completely emerged from the leaf sheath

Anthers dangle outside the florets during flowering

awn

Feekes

10.5.1

*The number of **flowers pollinated** determines the number of **kernels** that will develop*

KEY YIELD COMPONENT

anther

The male flower part that produces and releases pollen

pollen

The powder-like grains that enable fertilization

Feekes

10.5.2

The *developing head* is still vulnerable to freeze injury during low temperatures

Flowering continues toward the base

FLOWERING | Feekes 10.5.2 | Flowering complete to the top of the head

Anthers fade to white as flowering completes at the top of the head, while those toward the base are still brightly colored

Feekes

10.5.2

floret opened shortly after pollination to show developing kernel

Feekes

10.5.3

Zadoks 69

FLOWERING | **Feekes 10.5.3** | Flowering
complete at the base of the head

This stage
signals
the end of
pollination

Feekes
10.5.3

floret outer structure removed to
show developing kernel

This is the beginning of the **grain filling stages**;
kernel length is established during this stage

Feekes

10.5.4

Feekes

10.5.4

When squeezed, *clear fluid*
is released from the kernel

developing kernel with
desiccated anthers
still attached

Kernel size increases

but not dry matter
accumulation

Feekes

11.1

Zadoks 75

RIPENING | **Feekes 11.1** | Kernel milky ripe;
milk stage

Feekes

11.1

Dry matter accumulates
in the kernel

When squeezed,
milk-like fluid
is released from
the kernel

Feekes
11.2

Zadoks 85

RIPENING | Feekes 11.2 | Kernel mealy ripe;
soft but dry consistency; soft dough stage

Feekes

11.2

Green color of the kernel, glume and peduncle begins to fade

Starch, nutrients and dry matter
accumulate rapidly in the kernel

The kernel's content is a soft-doughy material

A close-up photograph of a corn cob, focusing on the husk. The husk is a mix of brown, tan, and green, showing signs of aging and drying. The leaves are pointed and layered, with some showing small holes or damage. The background is a plain, light color.

Feekes
11.3

Zadoks 91

RIPENING | **Feekes 11.3** | Kernel hard; difficult to divide with a thumbnail; hard dough stage

Feekes
11.3

Kernels reach their ***maximum dry weight*** and
are ***physiologically mature***

Kernel
moisture
decreases from
40% to 30%

Feekes

11.4

Kernel
moisture
decreases from
30% to 15%

Zadoks 92

RIPENING | **Feekes 11.4** | Kernel harvest ready;
straw dead

Green plant tissue fades to *straw*

Feekes

11.4

Other
cereals

To distinguish barley from wheat during the vegetative stages, check the auricles — barley auricles are long, slender and hairless, while wheat auricles are blunt and hairy

Barley

Auricles long, slender and hairless; leaf sheath and blade usually hairless (scattered hairs on some varieties); ligule medium length; leaf blades twist clockwise

Other
cereals

Other
cereals

To distinguish oats from wheat during the vegetative stages, check the auricles — oats lack auricles, while wheat auricles are blunt and hairy

Oats

Auricles absent; leaf sheath and blade hairless (scattered hair on some varieties); ligule medium length; leaf blades twist counter-clockwise

The background of the entire page is a close-up photograph of several oat panicles. The panicles are light brown and tan, with long, thin awns extending from the spikelets. The leaves are green and have a distinct longitudinal ribbing.

Other
cereals

Oats

A simple method to distinguish oats from all other cereals during the vegetative stages is to observe the twist of the leaves; when viewing from above, oat leaves will have a counter-clockwise curl, all other cereals' leaves curl clockwise

All other cereals

Other
cereals

*To distinguish rye
from wheat during the
vegetative stages, check
the auricles — rye auricles
are short and hairless,
while wheat auricles are
blunt and hairy*

Rye

Auricles very short and hairless; leaf sheath and blade have an inconsistent degree of hairiness; ligule short; leaf blades twist clockwise

Other
cereals

Other
cereals

The auricles of both triticale and wheat are blunt and hairy, so they are difficult to distinguish from each other during the vegetative stage

An alternative method is to remove a seedling from the soil and check the grain shell; triticale shells are oblong in shape and dark in color, while wheat grain shells are oval and lighter

Triticale

Auricles blunt and hairy, leaf sheath and blade hairy; ligule of medium length; leaf blades twist clockwise

Other
cereals
